THERE is no doubt but what the race for the cup presented by William K. Vanderbilt, jun., to be run on Long Island, U.S.A., on October 8th, will be an important international contest, although unfortunately this country will not be represented. The full list of entries is as follows:—By the German Automobile Club—Five Mercedes cars. By the French Automobile Club—Three 90-h.p. Panhards, to be driven respectively by Messrs. Heath, Teste and Tarte, an 80-h.p. Clement-Bayard, with Mr. A. Clement at the wheel, a Renault, and a De Dietrich. By the Italian Automobile Club—Two 90-h.p. Fiat cars, one being that of Mr. A. G. Vanderbilt, to be driven by Paul Sartori, and the other belonging to Mr. W. Wallace, of Boston. By the Automobile Club of America—Two White steamers of 60-h.p. each, one to be driven by Mr. Rollin White and the other by Mr. Webb Jay; two Pope-Toledos of 60-h.p. each, to be driven by Mr. A. C. Webb and Mr. H. Lyttle; one Royal Tourist of 36-h.p., to be driven by Mr. J. Tracy; a Simplex entered by Mr. F. H. Croker, and the Packard "Gray Wolf." The course over which the race is to be held is 32·4 miles long and has to be covered ten times; in shape it is an elongated triangle, the base lying to the eastward between Plain Edge and Jericho and the apex of the triangle being at Queens. The starting point is at Westbury, on the north side of the triangle, toward the base. The turns are all sharp ones, and are to be made to the right. There will be two "controls" on the course, one of three minutes and one of six minutes, at Hicksville and Hempstead, respectively. All cross roads will be barred and a hundred and twenty-five special constables will police the course. Dangerous curves will be oiled and probably the rest of the way watered. The allotment of numbers for the contestants and their time of starting will be made at the Automobile Club of America on the evening of October 1st.

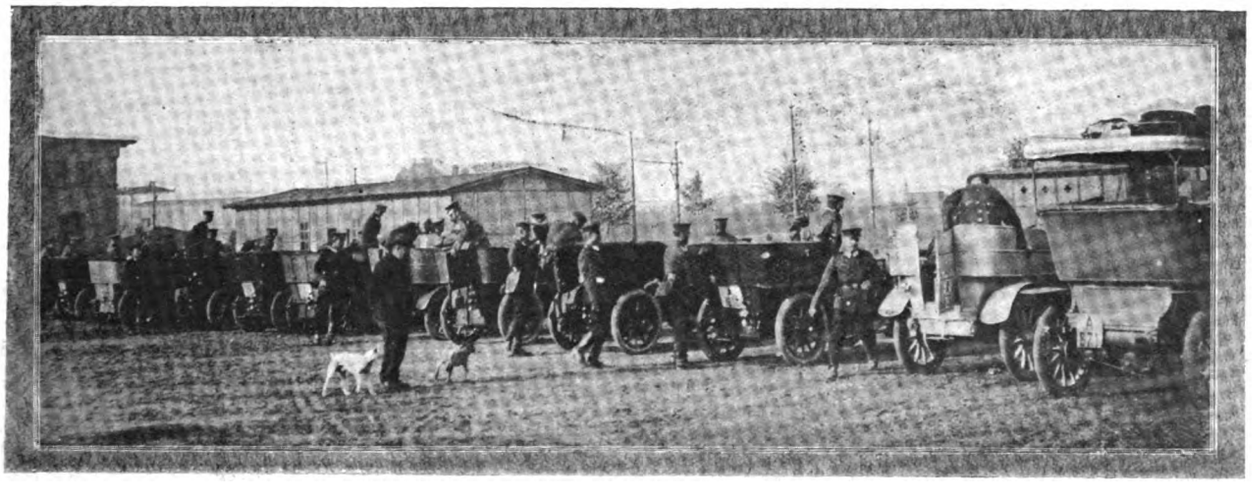
◆ ◆ ◆

Motoring in Canada.

MOTORING in the Canadian North-west is by no means an unheard-of thing, as might be imagined by those who think of the towns out there as collections of wigwams and tents. Winnipeg, Manitoba, for instance, which is by far the most important city in the Canadian North-west, has a flourishing automobile club, though at first there were about as many discouragements to motorists as could well be imagined. Probably the worst feature of all was—and still is, to some extent—the famous "Winnipeg mud," a particularly gummy brand of red clay that not only sticks to anything with which it comes in contact, like molasses, but is so slippery that it is a matter of no difficulty whatever for pedestrians to slide on it and fall. It can be imagined what this mud is in wet weather, and especially in the spring, when the snow is melting off. A large proportion of the country roads are simply tracks through this clay, and in really bad weather are absolutely impassable. In the city and its immediate vicinity, however, things are different, and there are now miles and miles of well-paved thoroughfares. The accompanying illustration shows some of the members of the Winnipeg Automobile Club with their cars in the grounds of ex-Mayor John Arbuthnot.

Motoring in Canada.—A Group of Members of the Winnipeg Automobile Club.

IN view of the forthcoming general meeting of the Marine Motor Association, proposed alterations of rules should be forwarded without delay to the secretary, Mr. James A. Smith, 47, Leadenhall Street, E.C.



MESSRS. J. WELCH AND J. BAYLEY, who have had considerable experience in the manufacture of radiators, bonnets, lubricators, &c., have severed their connection with the Doherty Motor Manufacturing Company, and have joined forces with Messrs. Walsh, Nicholls and Company, Wolverhampton.

THE COMPLETE MOTORIST.*

THE literature of the automobile is extending, and already our bookshelves are become crowded with a multitude of literary guides. The late Sir Henry Thompson was one of the first to write lightly of the motor-car; then followed the two great volumes of Mr. W. Worby Beaumont, volumes which already require to be brought up-to-date if they are intended to remain the standard work on the subject. Mr. Paul Hasluck's "Automobile" and Mr. W. Rhys-Jenkin's "Motor Cars" were two other volumes dealing with the modern method of locomotion. Mr. R. J. Mecredy's "Dictionary," and the *Badminton* book have also been widely read, to say nothing of the verbose work of Mr. Geoffrey de Holden-Stone, the chatty chapters of Major Matson and Mr. O'Gorman's Pocket Book.

Now comes another with the high-sounding title of "The Complete Motorist," and it must be confessed it justifies such a designation so far as is possible within the limits of about 300 pages. Mr. Filson Young is a practised book-maker, using the word in its literary significance, and has already shown his skill with the pen by writing of Mafeking, of Ireland, and of the Mastersingers. Latterly he has studied automobilism, to the advantage of automobilists, who may turn to his volume in full confidence of finding a good account of modern developments. Of the beginning of the motor-car little new can be said, although the illustration of Steven's sailing carriage of 1600 has not yet become so hackneyed as the drawings of Murdock's, Trevithick's, Gurney's and other pioneer coaches. Fortunately for the reader familiar with the early days, the first steps are quickly overtaken, and the pictures of Daimler's motor-bicycle of 1886 and the Peugeot benzine car of 1895 bring us to the period when Sir David Salomons and Mr. Evelyn Ellis did much to place the motor-car permanently upon English roads.

The Fleet of Cars engaged in the German Military Manœuvres.

Having introduced himself and the industry of which he writes, the author proceeds to deal with the petrol motor and its connections, giving a detailed description of the actual working of the engine and its various accessory parts. Transmission and control also form the subject of some excellent pages. Proceeding to the various types of petrol car on the market, Mr. Young makes reference to the competition of English and Continental makers. He rightly recognises that some of our own firms are now holding their own with the best types of French and German manufacturers, although a qualification is made with respect to the ordinary makes, for "the average of their (the British makers) work is still below the average of, say, the French makers." With regard to the present position, Mr. Young says:—"It cannot be said that the British manufacturers have hitherto fully availed themselves of Continental experience, for some of the best-known English motor-cars are designed, if not with a contempt for, at any rate with a complete avoidance of, Continental practice; and the result is that although the makers of English cars of repute are few in number as compared with the French and Germans, their practice shows far greater variety and lack of unanimity, even with regard to broad principles of construction." Chapter IV. is one of the best in the book, and the way in which the author describes the manner of construction of a modern motor-car is admirable. Few will quarrel with the selection of types which are explained in detail, viz., the Crossley—placed first because, in Mr. Young's opinion, it "bids fair to place English motor-car construction at last on a level with that of the Continent"—Napier, Mercedes, Lanchester Daimler, De Dietrich, Wolseley, Renault, Duryea, Hutton, and Thornycroft. This division of the work might be usefully supplemented with a series of tables summarising the various cars in the varying types, giving the sizes in which they are made and the prices at which they are sold. Such matters are sometimes not easy to find in the text; their setting in tabular form, supplemented by mention of other vehicles otherwise unenumerated, would be useful to the reader, and remove from the author's mind the fear of invidious selection. Certainly the suggestion is worthy of consideration when the book reaches its second edition—as it should do very quickly.

Steam cars, now under a "temporary eclipse," are the subject of a chapter which is, in many ways, the least satisfactory in the book. We are surprised, for example, that nearly three times the space should be devoted to a new car with whose performances the public are unfamiliar, as to such a vehicle as the "White," which, despite the failures of other American vehicles in this country, has earned a high name among steam vehicles. Mr. Young is far happier when writing of petrol vehicles, and his points as to the selection of a car will be useful to all. "The first test of a motor-car is, of course," he says, "the test of the road. A car should be given a good trial of not less than a hundred miles on what is called a give-and-take road, and the possible purchaser should study very carefully its behaviour during the test. If any adjustments have to be made he should satisfy himself as to whether they are rendered necessary by the ordinary shaking-down process incidental to all newly assembled machinery, or whether they are due to inherent imperfections of design or construction. The loosening of a bolt, however drastic its effect upon the running of a car, may mean nothing; but irregularities of speed, difficulties in gear changing, heating of the engine, difficulty in starting, although they may have comparatively little effect upon the day's run, may possibly mean a great deal." Other chapters are concerned with the running of cars, small automobiles, tyres, etc., and followed by interesting letters, completing a book which has attained a standard reputation on first publication.

* "The Complete Motorist." By A. B. Filson Young. London: Methuen and Co.

CONTINENTAL NOTES.

The International Motor-Bicycle Race.

The motor-cycling world is now looking forward to the international motor-bicycle race which is to take place on Sunday next. The English competitors in the contest are Messrs. T. Silver, Quadrant; Harding, Lagonda; and Hodgkinson, J.A.P France will be represented by three Griffon machines, ridden respectively by Lamberjack, Inghibert and Demester. For Germany, Adolf Mraz will ride a Progress-Charlottenburg, and for Denmark H. C. Nielsen will pilot a Jorgensen, while Austria will be represented by Messrs. Wondrick and Jomann, both on Laurin-Klements. The race is over five circuits of a 32½ miles course, starting from St. Arnoult, by Dourdan, Boutervillers, and Ablis. The Austrian competitors reached Paris on Monday evening, while the English team arrived on Wednesday morning.

◆ ◆ ◆

The Queen of Holland's First Automobile Trip. [De Auto.

◆ ◆ ◆

Motor-Boat Racing in Denmark.

A joint meeting has recently been held in Copenhagen of the Danish Automobile Club, the Automobile Industry Association, and the Motor Cycle Club, when a committee was appointed to deal with the proposed Scandinavian automobile and motor boat races, which are to be held in the Sound early in June, 1905.

◆ ◆ ◆

The Chateau-Thierry Hill Climb.

The Prefet of the Aisne having given the necessary authorisation, the annual hill climbing competition at Chateau-Thierry, organised by the "Auto," is to be held on October 23rd. The event is reserved for touring vehicles, the racers' "day out" being at Gaillon on October 30th.

◆ ◆ ◆

Motor Boat-Racing at Juvisy.

A motor-boat race meeting is to be held at Juvisy, near Paris, on the 25th inst. The morning will be devoted to the cruisers, for which there will be several races of 36 kilometres starting at Ablon and finishing at Viry-Chatillon. In the afternoon there will be a 100 kilometre event for racers up to 8 metres, and one over the same course for vessels from 8 to 12 metres in length. All the well-known boats, including Mercedes IV., M. Fournier's Hotchkiss, the Panhard Rapée and three Clement-Bayards, have been entered for the meeting.

◆ ◆ ◆

Reliability Trials in France.

It is announced that the Automobile Club of Seine-et-Oise intends to organise a series of reliability trials in February next, the daily runs starting from Versailles.

◆ ◆ ◆

An Italian Tourist's Guide.

The excellent publications issued by the Italian Touring Club have been frequently referred to in these columns. The latest effort is an *Annuario dell' Automobilisma*, or automobilist's annual handbook, which reflects great credit on all concerned in its production. It is, of course, intended for the use of Italian motorists, in whose language it is printed, but it will prove almost indispensable to all foreign motorists touring in Italy. Beginning with a brief description of the petrol motor and motor vehicles, the subjects of Italian customs duties and motor traffic regulations are next dealt with. Then follow a list of the motor clubs, owners of automobiles, builders and repairers of motor-cars and motor-boats, petrol and lubricating oil depots in Italy, &c. The second part is devoted to the clubs, traffic regulations, customs duties, &c., in foreign countries.

◆ ◆ ◆

The Transatlantic Motor-Boat Race.

The offer of a prize of £2,000 for the first motor-launch to cross the Atlantic Ocean is attracting considerable interest, and looks like providing one of the most sporting events of the year. A committee has been appointed to draw up rules, but in the meantime entries are rolling in, there being already over a dozen, including Mr. Noé Boyer, with a 100-h.p. boat; M. Henri Fournier, with a Hotchkiss craft to be something between 58 ft. 6 in.

Digitized by Google

and 81 ft. 3in. in length; M. Charley, with a 65 ft. Mercedes boa; and Mr. S. F. Edge, with the nominal 300 h.p. Napier boat that is being built to carry six passengers and a crew of two men.

◆ ◆ ◆

Another Motor Boat Cup Race.

A challenge cup of the value of £1,000 is being offered by M. Boin-Taburet for motor-boats, employing heavy oil as fuel, of such a character as to be suitable for Colonial service. The boats must be of a minimum length of 12 metres, and have a maximum draught when fully laden of ·8 metre, and must attain a minimum speed of 10 knots. Each boat, whether decked or otherwise, entered for this cup must be so constructed as to be capable of being employed, first for towing purposes, secondly for the transport of troops or of goods. The cup is to be competed for at Trouville annually in one stage of ten hours. The classing will be governed by (1) number of kilometres run (2) the fuel consumption during the run. The winner of the cup will receive a money prize of £40, and the second boat classed £20.

◆ ◆ ◆

Motor Boats in Sweden.

Under the auspices of the Swedish Automobile Club a motor-boat regatta has just been held at Waxholm. Motor-boating has recently become very popular in Stockholm, and the thirty-eight boats which took part in the event were the centre of much interest.

◆ ◆ ◆

Wanted, a Name.

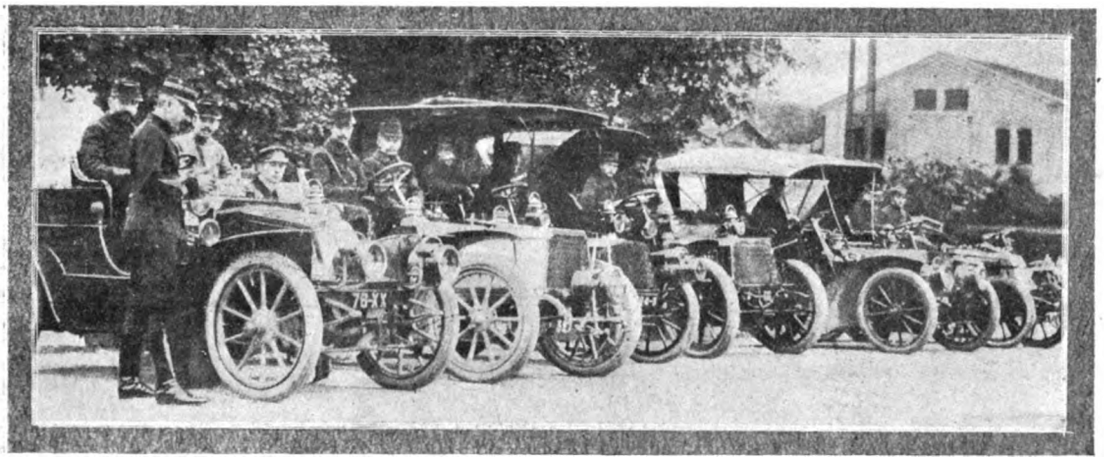
Considerable interest is just now being evinced in French motor-boating circles in the question of a suitable word for motor-boats. Here are a few of the words which have been suggested. "Motoscaphe," "Autonef." "Autocanot," "Canot Automobile," "Autoscaphe," Automobile-Canot." The French Academy has been appealed to, but M. de Herida, of that body, while personally favouring "Autoscaphe," replies that the function of the Academy s not to create words, but to register new words which may come into general use.

◆ ◆ ◆

Motor-cycle Racing in Bohemia.

The Bohemian Motor-Cycle Club is organising a motor-cycle road race for the 9th October. The course is from Prague to Pisek, a distance of 100 kilometres. In conjunction with the event there will be a hill-climbing competition from Pisek to Nava Hospoda.

◆ ◆ ◆



Motor-cabs in Berlin.

A service of motor-cabs is about to be started in Berlin by a company which has just been formed with a capital of £3,500 and with the title of the Berliner Motor-droscken Gesellschaft.

◆ ◆ ◆

The Renard Road Train.

An interesting scheme is under consideration at St. Malo, where it is proposed to run a road train, on the system of Colonel Renard, between St. Malo, Parame, St. Idenc, La Guimorais, St. Coulomb, Cancale, Doe, St. George de Grehaigne, Pontorson, and Mont St. Michel. This train was much in evidence last year at the Automobile Exhibition in Paris, and several trials were made in the streets of Paris with remarkable success.

As in England, Motor-cars were extensively used in the Military Manœuvres just held in France. The above illustration depicts Captain Genty, himself an enthusiastic Motorist, reviewing the vehicles.

A Complaint against Petrol Distillers.

Complaints are rife in Paris against the distillers of petrol, who, it is asserted, are not giving full measure. One well-known motorist states that he has measured the contents of the five-litre sealed cans he has lately purchased, and that he finds them to contain from ten to fifteen per cent. less than the correct quantity.

◆ ◆ ◆

Hill Climbing in Switzerland.

The Swiss Automobile Club is organising a hill-climbing competition from a standing start on the road between Trelex and Saint Cergues (Vaud) on Sunday next. The distance is ten kilometres, there being a rise of 500 metres between the starting and finishing points.

◆ ◆ ◆

The Semmering Hill Climb.

The annual hill climb from Schottwein to Semmering organised by the Austrian Automobile Club is to be held next Sunday, when some fast times should be recorded. The entries in the heavy car class include a 90-h.p. Austrian Mercedes, driven by Braun, a 80-h.p. Darracq, a 75-h.p. Fiat driven by Lancia, a 80-h p. Opel-Darracq, a 60-h.p. Regent and Mr. Clarence Gray Dinsmore's 80-h.p. Mercedes, which will be driven by Herr W. Poege, Werner having left for the United States to take part in the Vanderbilt Cup race. Three cars have been entered in the voiturette section, while about twenty motor-cycles will also compete.

◆ ◆ ◆

The Gordon Bennett Race.

The German Club has granted the Daimler Motoren Gesellschaft two places in the German team for the 1905 Gordon Bennett team without competition, and will further allow them to compete in the eliminating trials for the third place.

◆ ◆ ◆

Speed Trials at Dourdan.

The "Velo" is organising a series of speed trials to be held on the Dourdan road on October 3rd. The trials will consist of a mile competition with a standing start and the flying kilometre. The racing section provides for: (1) motor-bicycles weighing under 50 kilogs.; (2) motor-bicycles from 50 to 80 kilogs.; (3) motor-cycles from 80 to 250 kilogs.; (4) voiturettes from 250 to 400 kilogs.; (5) light cars from 400 to 650 kilogs.; and (6) heavy cars from 650 to 1,000 kilogs. The categories in the touring class are (a) motor-bicycles under 60 kilogs.; (b) motor-cycles; (c) cars costing from £160 to £320; (d) ditto, £320 to £480; (e) ditto, £480 to £720; (f) ditto, £720 to £960; (g) ditto, £960 to £1,200; and (h) ditto over £1,200.

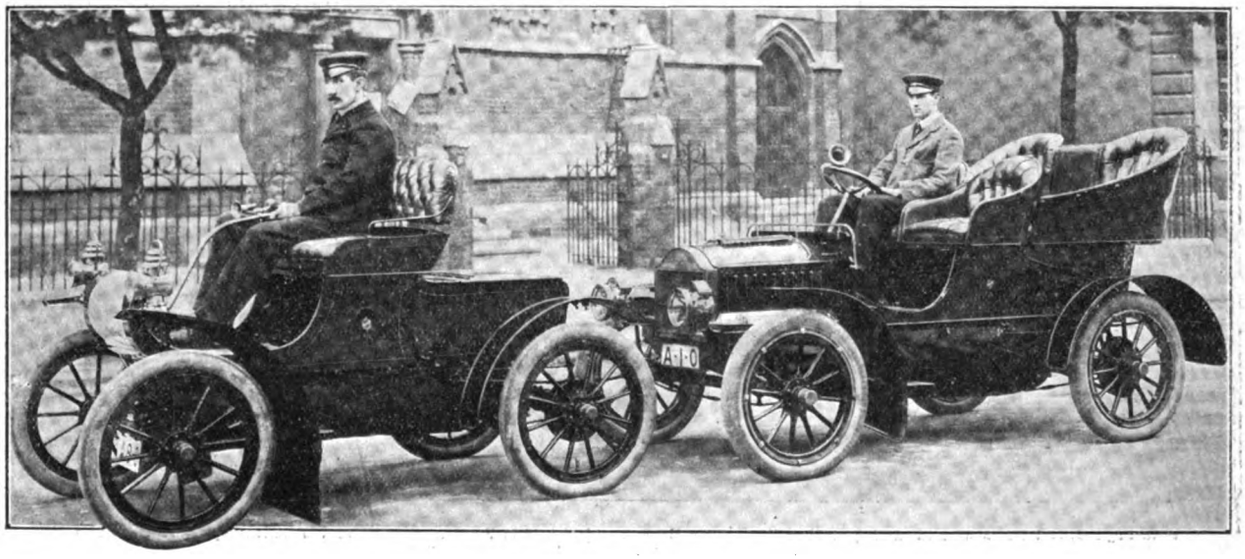
A THIRTY DAYS' TRIAL.



A GREAT deal of interest is being taken by the public in the small car, or the car for the man of moderate means. A great deal of this concern is due no doubt to the recent reliability trials at Hereford, following which Messrs. Jarrott and Letts, Limited, have put two Oldsmobiles on the road for an extended trial. On Wednesday the two vehicles—one a two-seated car, and the other a four-seated light tonneau—started from Great Marlborough Street, London, each car carrying two people and their entire luggage.

The idea is that the cars will do 50 miles in the morning and 50 in the afternoon, making a total of 100 miles per day, and this for 30 days makes a total of 3,000 miles, throughout England, Scotland, Ireland and Wales. The observer who will accompany each car will keep a record of everything that happens. The cars will be run under the ordinary conditions that any man would expect to run his little car, *i.e.*, to take half an hour in oiling the vehicle and looking carefully over it, then do 50 miles non-stop in the morning, stop at mid-day for lunch, again oil up his car and do a further 50 miles in the afternoon, non-stop.

The observers will report to Messrs. Jarrott and Letts, by telegraph, the arrival at the destination each day, and a large map will be shown at the offices in Marlborough St., whereon flags will denote the distance the cars have travelled each day, and where they are; but in case there should be any question of the cars not touching the different towns, the driver of each vehicle will carry a book which will be signed by the proprietor of the hotel where lunch is taken at mid-day, and the hotel at which they stay each night, so that an absolutely reliable and independent record will be kept of all the towns at which they stop. The cars are both painted red, and a map of the route is also painted on the side of the car, and the distance that the cars have to cover, so that the public in the different towns will know exactly how far they have come, where they are going and all about them.

Starting on Wednesday last, the destinations to be reached each day are as follow:—First day, Bournemouth; second day, Brighton; third day, Dover; fourth day, London; fifth day, Norwich; sixth day, Nottingham; seventh day, Leeds; eighth day, Newcastle-on-Tyne; ninth day, Edinburgh; tenth day, Glasgow. The further routes will be published in subsequent issues of the *Journal*.

The vehicles attracted much notice as they sallied forth from Great Marlborough Street towards Hyde Park Corner, attended by a long line of other cars, including Spykers, Bollees, Crossleys, and De Dietrichs, driven by the principals and assistants of the firm to whose enterprise this new attraction of the road is due.

The Two Oldsmobiles which started on a Thirty-Days' Trial on Wednesday.

SOME USEFUL NOTES.

WHEN travelling over rough roads, the driver should sit in such a position that the feet will not be shaken off the pedals. Otherwise, when the clutch is disengaged, as it should always be for a rough spot, and the car allowed to "coast," the feet may be jarred off the pedals, allowing the clutch to slam in, and causing great strain on the gears and transmission mechanism.

◆ ◆ ◆

WHEN about to pass over holes in the road, or short patches of loose stones, the car should have sufficient momentum to carry it over such rough places, so as to allow the clutch to be disengaged. This prevents racking the mechanism.

◆ ◆ ◆

THE low speed gear should invariably be used when starting the car, as this saves both the clutch and the transmission. Cars having powerful motors may be started on the third speed, but this does not do the vehicle any good and may do it a great deal of harm. A practice which should be avoided as much as possible, and which is responsible for many broken gears, chains, and twisted shafts, is that of "racing" the motor before the car is started, and then dropping the clutch in.

As serious accidents often occur when a car "skids," it will pay to be careful when running on wet pavements, particularly asphalte. "Skidding" is more likely to occur when the surface of the road is about half-wet, as it is then in the condition known as "greasy." It will be generally found that a car skids less when the side or emergency brakes are used than when the foot brakes are used. The latter usually act through the differential gear, and the former directly on the rear wheels. A car on which the brakes on the rear wheels are adjusted precisely alike, so that they both grip equally, will skid much less, other things being equal, than one on which the brakes are adjusted unequally.

◆ ◆ ◆

WHEN the car skids, remember that putting on the brakes hard will make matters worse. About the only thing which can be done is to take out the clutch, keep the brakes gently on, and steer the front of the vehicle in the same direction as the back tends to go. When driving a car fast on a slippery road it is best to drive close to the kerb. Then, if one wants to stop suddenly, the front wheels should be turned slightly away from the kerb and the brakes applied. The back wheels will then slide against the kerb, and cannot, of course, skid any further.

MR. P. REID, the well-known carriage builder, of Perth, has opened a garage in that city, where he will have accommodation for a hundred automobiles.

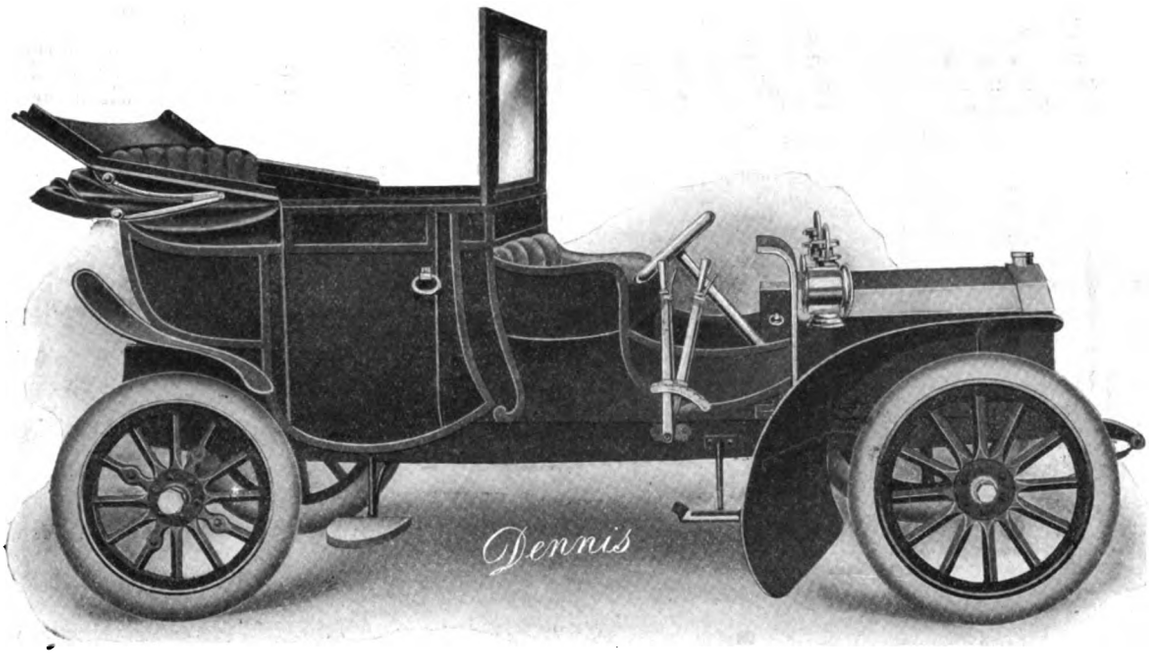

Fig. 1.—The Dennis 20-h.p. Landaulet.

THE 20-H.P. DENNIS CAR.

WE have already briefly dealt with the 20-h.p. car built by Messrs. Dennis Bros., Limited. Recently, however, we had an opportunity of going more closely into its details, when many new points revealed themselves, a description of which may not be without interest. The main frame of the vehicle is of stamped steel, the forward end being so reduced in width as to allow of an extremely large wheel lock, permitting the car to be turned in comparatively narrow roads. An underframe is provided to carry the engine and change speed gear. The motive power is supplied by a four-cylinder Aster engine of the latest type, with mechanically operated inlet valves. The usual type of electrical ignition is provided, the contact

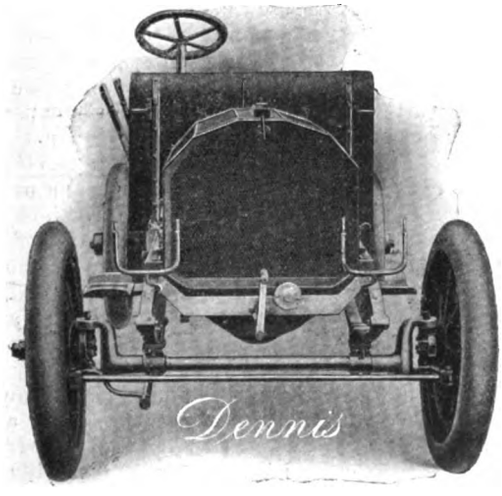

Fig. 2.—Front View of 20-h.p. Dennis Car.

maker being located right in front, below the radiator, and is therefore extremely accessible for adjustment. The water circulation is maintained by a gear-driven pump and a honeycomb radiator, a current of air being drawn through the latter by a belt-driven fan.

The clutch is of the usual cone type, but of large diameter, and is provided with a detachable loose joint between it and the gear-box, which permits of the clutch being taken down without having to disturb any other part. The spring is located within the clutch, and is provided with a ball-thrust race. Three speeds forward and a reverse are controlled by one lever.

The gear box is a substantial aluminium casting, and contains a set of gear wheels of ample width; on the top speed, the drive is direct, with none of the gear wheels in mesh. The secondary shaft itself is a fixture, the gear wheels being keyed to a sleeve, which is steel bushed, and rotates on the fixed shaft. Automatic lubrication is ensured to this sleeve by oil scoops formed thereon, which pick up the oil in the box and pass it to the bearings. The bearings of the primary gear-shaft are lubricated from an exhaust pressure feed lubricator on the dashboard. The gear is changed by the horizontal swinging lever seen within the gear box (Fig. 4), the spindle of this lever protruding through the top of the box, which is practically oil-tight. From the gear-box to the universally jointed propeller shaft the power is transmitted through the Dennis spring drive arrangement, which has already been illustrated in the *Journal*.

One of the principal features of the car is found in the method of conveying the power to the rear live axle. In place

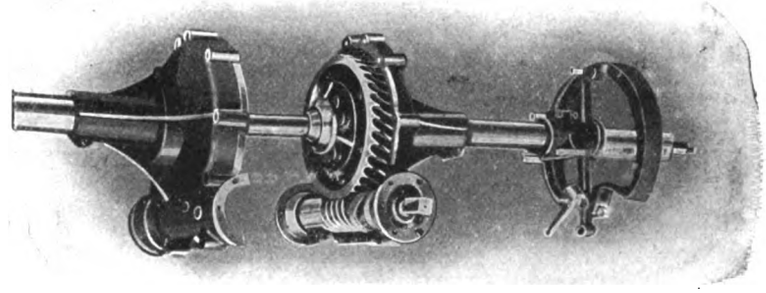

Fig. 3.—The Dennis Worm Drive.

of the usual bevel gear transmission, Messrs. Dennis have adopted a worm gear, the worm being enclosed in the upper portion of the differential gear-box, and running at each end in phosphor-bronze bearings. Ball thrust bearings are placed so as to take up thrust either forwards or backwards. The worm is formed with a quick-pitched thread, and drives either forwards or backwards with equal smoothness. The worm wheel, which is of phosphor-bronze, encircles the differential gear, the latter being

Digitized by Google

of the parallel pinion type, with six pinions and two star pinions. The rear road wheels are not mounted on the axle proper, but on a sleeve, consisting of a malleable casing, surrounding the latter, the power being conveyed from the axle to the wheels by jaw clutches in the hubs. The live axle runs on 5-8 in. ball bearings. The lubrication of the rear axle is provided for by

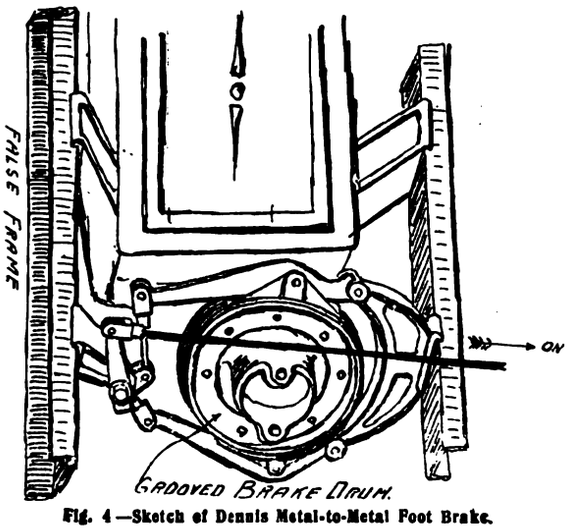

Fig. 4.—Sketch of Dennis Metal-to-Metal Foot Brake.

the supply of graphite and oil to the worm case through an inspection cover on the upper side of the case, access to which is through a small trap door in the floor of the car.

Another novel feature of the Dennis car is the foot brake, which surrounds the spring drive immediately in rear of the gear-box. It is of an exceedingly powerful type, the steel drum being provided with a series of grooves similar to a rope driving pulley. At the top and bottom of this are mounted phosphor-

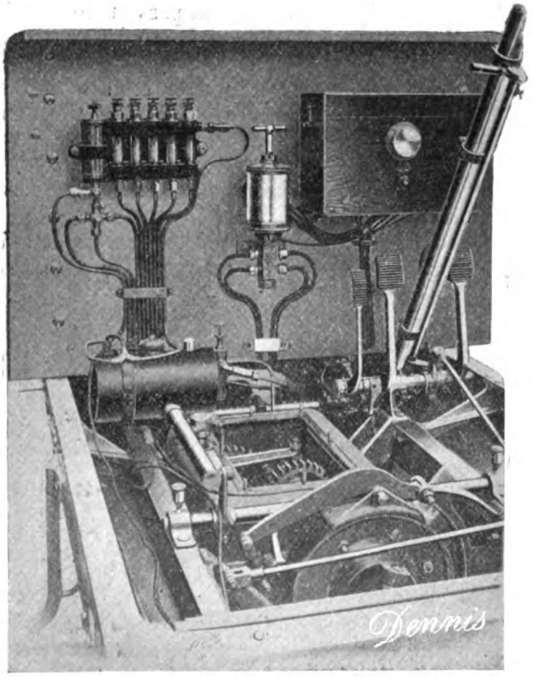

Fig. 5.—View of Dashboard, Gear-box, Foot Brake, etc., with Foot-boards up.

bronze shoes, each provided with grooves corresponding to those on the drum. It will be readily seen that by means of the grooves the braking surface is greatly increased. The rear brakes are of the internal expanding type, consisting of two shoes acting at equal distance on the inner face of the steel drum. Both the foot and hand brakes, it may be added, act equally well whether the car be running in a forward or backward direction.

The steering gear is of the irreversible worm and sector type. As will be seen from Fig. 2, the front axle is formed of a straight piece of tube, and the arms which carry the swivel are fitted with hardened steel cups top and bottom, in which the steering centre rotates. The bottom cup is made adjustable to take up any play, and is locked by a set screw, there being no pins running through the steering centre, which gives it additional strength. The engine and gear-box are protected from mud and dirt by an aluminium casing attached to the frame, which extends to the rear end of the gear-box. The road wheels are of special design and exceedingly strong. They are of what is known as the double artillery type, the spokes diverging from each other where they leave the hub and entering the felloes anglewise.

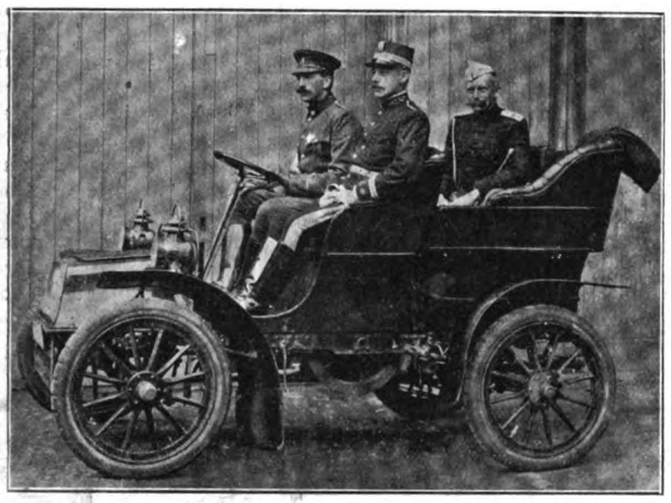
The mixture is furnished by a Longuemare automatic carburettor, so that only two levers are necessary to control the speed of the engine—a hand lever connected with the ignition, and a pedal which acts on the governor and allows the speed of the motor to be accelerated. The wheel base of the standard car is 7 ft. 6 in. Recently, however, to meet the demand for side-entrance cars, a handsome double phaeton and a laudaulet, with 8 ft. wheel base, have been introduced. A view of one of the latter is given in Fig 1.

Being somewhat sceptical of the worm drive, we recently accepted the invitation of Messrs. Dennis to a thirty-mile spin on one of these cars, and are free to admit that we were surprised at the ease and quietness with which it ran. Indeed, on the top speed the only sound we could hear was the ticking of the trembler four-cylinder induction coil. On the run we had evidence as well of the speed qualities of the car as of its hill-climbing capacities, Mr. R. Dennis driving us almost to the top of the Hog's Back, out of Guildford, on the top speed. Altogether the Dennis 20-h.p. car is a well-thought-out vehicle, and merits the success which it is achieving.

INSTRUCTION BOOKS.

ONE noticeable improvement in the automobile movement which will conduce to the mutual advantage of user and manufacturer is the helpful instruction books which are being furnished to purchasers of modern cars. Until recently there has been a lack of definite information furnished the owners of vehicles relative to the lubrication of their cars, the adjustment of parts and the derangements to which the various portions of the mechanism are likely to be subject, and their remedies. Some of the larger and older manufacturers have long furnished books of directions which were valuable in that they contained matter which was the result of the experience of a great many users and thus laid due stress upon the points which service had demonstrated to specially require elucidation; but many of the smaller and newer concerns have naturally been unable to furnish as satisfactory and useful directions to their patrons, on account of the somewhat untried character of their product and the lack of the experience necessary to demonstrate what particular matters the instructions should include.

The tendency which formerly seemed to exist to allow the user to find out through experience what might better have been told him in the beginning, appears to have passed away with the growth of the spirit of candour in the industry, and now the instruction books generally contain particular advice as to the peculiarities of the cars to which they refer, and are written in a lucid and comprehensive way with full diagrammatic illustrations which cannot fail to lead to a more intelligent use of the car by its owner and a better *entente* between the manufacturer and his patron.



However much information a motorist may possess as to motor vehicles in general, there is still a most urgent need for particular detailed instructions referring to the special car he is using, for no amount of general information will instruct him as to the special methods of lubrication and adjustment and the easiest manner of disassembling and assembling the various portions of a specific machine in which the details of construction necessarily differ in many minor respects from all others.

HERE AND THERE.

MESSRS. STANBURY AND CO. intend to make motor-car bodies on premises lately acquired at Prescot Street, Liverpool.

THE Collier Tyre Co., Ltd., have changed their address, having removed from Shaftesbury Avenue to 127, 128, 129, and 130, Long Acre, London, W.C.

The Military Manœuvres.—The Cadillac Car driven by Lieut. P. W. Northuey. At his side is seated the Spanish Military Attache, Col. J. de Manzanos, with Capt. Alex. de Kauffmann, A.D.C. to the King of Denmark, in the tonneau.

MR. L. M. MUSGROVE, of Brixton, is endeavouring to organise a benefit society in connection with the motor industry, and has forwarded us a statement of allowances which could be granted to members in the event of certain payments being made. We do not know on what actuarial calculations these have been based, and it would appear that the scheme is still in an embryo stage.

AS shown in our columns last week, the motor-cars used in the recent military manœuvres proved a great success. The

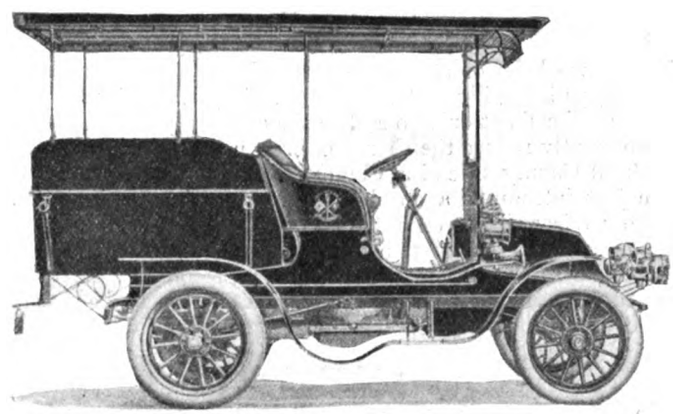
The Military Manœuvres.—General French on Mr. Stanton's Car. Prince Alexander of Teck is a Passenger on the other Vehicle.

vehicle upon which Mr. O. Stanton drove General French, illustrated on page 630, was supplied with an outfit by Messrs. Alfred Dunhill, Ltd., the accessories including a rifle case so placed that the rifle can be extracted by the driver without leaving his seat. Our photographs of General French were taken by Mr. Herbert Smith, a director of the Association of Diamond Merchants and Silversmiths, Ltd., with a Kodak camera.

THE Glasgow and South Western Railway have recently built at their works at Kilmarnock a steam motor-carriage.

ON the main road between Carlisle and Glasgow, at Dumfries, the local Brass and Iron Foundry Company have opened a free garage.

THE expenditure on the roads in the Kington Rural District, said to be the best in the county of Hereford, is £8 per mile under the county average.



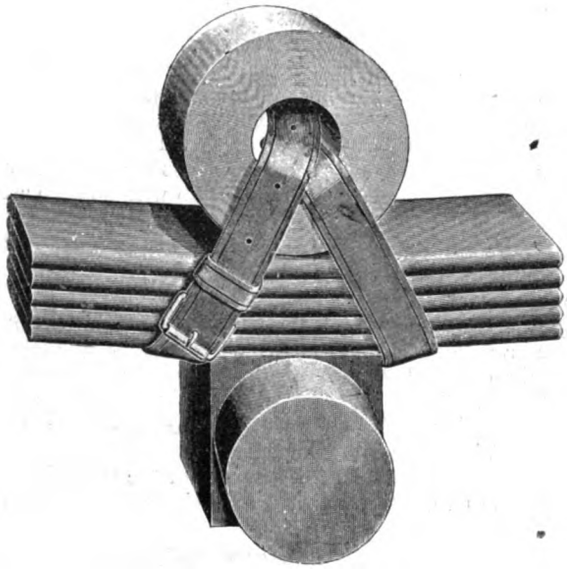
IT is reported that Messrs. Panhard and Levassor are building a new type of 50-h.p. touring car, which will be shown for the first time at the Paris Salon in December next.

MESSRS. STEVENSON AND COMPANY, Polmadie Saw Mills, Rutherglen Road, Glasgow, inform us that they have taken up the manufacture of artillery pattern wheels for motor-cars.

AS already announced, the Aero Club will hold an ascent at Birmingham to-day, Saturday, in connection with a meet of the Midland Automobile Club. The aeronauts in charge will be Mr. Frank H. Butler and Mr. C. F. Pollock, and prizes will be given for the cars which will succeed in capturing the balloons.

MESSRS. VAN RADEN AND COMPANY, Coventry, have lately introduced a single trembler coil which will fire a double-cylinder motor, and a double-trembler with two coils to operate a four-cylinder motor. They are now also making a specially cheap small high-speed trembler coil for motor-cycles, of which one firm has, we hear, already contracted for two thousand.

THE illustration herewith shows one of the two Winton cars ordered by the U.S. Government for the signal service. As men-



tioned in a recent issue of the *Journal*, one of the cars took part in the August manœuvres on the Pacific coast and the other is participating in the Manassas manœuvres this month. The official title of the vehicle is "Signal Corps Telegraph Auto-Car." In the rear of the car is a table to hold telegraph instruments for two men and space for telephone, wire, shovels, and other tools necessary to erect telegraph lines.

THE N.A.G. Automobile Company of Great Britain and Ireland, Limited, has been registered with a capital of £10,000 to adopt an agreement with Messrs. T. L. Spencer and C. E. R. Holmes, and to carry on the business of automobile storers, garage keepers, manufacturers of and agents for motor-cars and carriages. The registered office is at 106, Great Portland Street, W.

AMONG the latest non-skidding and puncture proof bands to be brought before the notice of motorists is the "Sawyer," made by Messrs. Sawyer and Co., of Kensal Rise. The band is made of chrome leather of an extra special tannage; steel studs are inserted on the tread, which effectually prevents any possibility of side-slips and punctures. It is claimed for the bands that they do not interfere with the resilience of the tyre, and are equally effective for light or heavy cars. As the whole of the tyre cover is protected by the leather band, the latter tends to strengthen the tyre, as it is impossible for the damp to penetrate through the material used. The bands are made for all sizes of motor-cars from 650 by 65 mm. to 1,370 by 120 mm., and can also be supplied for motor-cycle tyres, for which they are strongly recommended. The dreaded side-slip is stated to be rendered impossible, no matter how greasy the road may be.

THE Continental Caoutchouc and Guttapercha Company has lately brought out a series of rubber buffers for attachment to the springs of motor-cars, to reduce the shocks due to the body of the vehicle, when travelling over rough roads, bumping on the springs. The buffers are made in a variety of forms and with

different methods of attachment to suit all kinds of spring, a simple type being illustrated herewith. They are easily attached and are claimed not only to add to the comfort of the passengers but to greatly reduce the chance of broken springs.

THE County Chemical Company, Limited, of Birmingham, have just introduced a novel puncture repairing device known as the "Wizard." It consists of two metal parts, as illustrated. The upper or larger portion is a light saucer-shaped brass cap carrying a screw stud in the centre, and is radially slotted, as shown in the illustration. When a puncture has to be mended, the edge of this slot is inserted in the puncture in the air-tube

(which is widened so as to admit it). The saucer is then worked through the puncture until it is entirely inside the tube. The screw stud is then pulled through the puncture, and the top portion, or cap, is screwed home on the saucer. The repaired tube then appears as in the lower illustration, and can be at once inflated, the cover replaced, and the journey resumed. The action of the saucer and the stud coming together is to form an air seal around the edge of the saucer, into which the upper stud recesses. The repair thus effected will stand as long as the tube may be used, and we need scarcely add that it is not possible for another puncture to be made in the same place. The discs are made in three sizes—1 in., $1\frac{1}{4}$ in., and $1\frac{1}{2}$ in. in diameter—and can be used for repairing $\frac{1}{2}$ in., $\frac{5}{8}$ in., and $\frac{3}{4}$ in. cuts or punctures respectively. Therefore, with a selection of these discs in his possession, the motorist can confidently tackle the repair of any ordinary puncture, and have his car running again in a few minutes.

THE first mishap that has occurred to the mechanical transport used in the recent manœuvres in East Anglia happened on Friday of last week, when a tramcar and a supply wagon, drawn by a military patrol car, came into violent collision on Lexden Road, Colchester. The front part of the tramcar was smashed in, whilst the forecarriage was knocked off the wagon, and its contents were scattered broadcast.

AMERICAN motor-car builders and accessory manufacturers will shortly receive from the United States Census Bureau schedules of inquiries which they are expected to fill up. The schedule to be sent out includes returns covering the character of the organization, date when present organization commenced

The 6½-h.p. Royal Humberette, with Cabriolet Canopy, which gained the First Prize in the recent Hill-Climbing Competition at Gainsboro'.

operations, capital invested, number of proprietors and firm members, salaried employees, wage earners, including piece workers, miscellaneous expenses, materials used, value of products, power employed, and various other items. The statistics to be collected will cover the business year of each manufacturing establishment most nearly conforming to the financial year ending June 30, 1904.

THE Belsize Motor Car and Engineering Company, Limited, held their first annual general meeting at the Midland Hotel, Manchester, on Thursday of last week, Mr. G. P. Dawson presiding. In moving the adoption of the report, the Chairman said he was glad to be able to say that the company was maintaining its position, and obtaining its fair share of orders. Their works at Clayton, Manchester, were well employed, and their orders for the coming season were above the average of past years, owing mainly, he thought, to the very high reputation the company's three-cylinder cars had made for themselves. The report was adopted, and it was decided to pay a dividend at the rate of 5 per cent. per annum and to carry forward the balance to the reserve fund.

MOTOR CYCLING NEWS.

A FUEL consumption trial organised by the Auto-Cycle Club will be held on the 1st prox. On November 30th the club will hold its annual dinner at the A.C.G.B.I.

◆ ◆ ◆

ONE of the most frequent causes of unsatisfactory running of tri-cars and small air-cooled engines generally is "overheating," and this is more particularly noticeable when a two-speed gear is fitted. The overheating arises from causes for the most part inherent in this type of vehicle, and it cannot be altogether eliminated, except perhaps by the most careful and experienced driving. Neglecting such remedies as fans, etc., the usual remedy is to water cool the engine in one way or another. This method is efficient, but, on the other hand, it adds considerably to the weight of the machine, renders the parts less accessible, and generally complicates matters, as well as increasing the cost. To overcome the difficulty in a simple way Clarke's "Ejector" cooler has recently been introduced by Mr. L. Anderson, who claims that it affords a highly efficient,

reliable, and durable remedy for "overheating." It weighs but a couple of pounds, is easily fitted, and it works as long as the engine runs. As will be seen from the illustration, the "Ejector" cooler is fitted in conjunction with the silencer in such a way as to cause the exhaust gases to induce a powerful draught of cold air, which is directed upon the cylinder in a continuous stream. The device is automatic, and needs no power to drive it. It causes the air draught to correspond with the speed of the engine, without either causing or providing a tendency towards "back pressure." A Tri-car, fitted with one of Clarke's "Ejector" coolers, 75 by 80 mm. engine, two-speed gear (12 to 1 on low gear), carrying 25 stone, has, we learn, been driven up Westerham Hill and Dover Castle Hill without pedalling.

◆ ◆ ◆

ON Thursday and Friday of last week the Auto-Cycle Club's Reliability Trial took place, its interest being mainly centred in the novel system of fining by means of which the prize list was to be enhanced. Starting from Staines on the first day were Messrs. M. Ponder (2¾-h.p. Humber) F. Applebee (3¼-h.p. Dux), Mr. Hayes (who retired from the contest at Salisbury), Mr. O'Gorman (3½-h.p. Ormonde), H. J. Densham, 2½-h.p. Anglian), J. J. Leonard (2¾-h.p. Lurquin), and H. P. Rose (2½-h.p. Roc). Exeter was reached in the evening, and on the following day the riders made for Southampton, where Messrs. O'Gorman, Densham, Leonard and Ponder arrived shortly after 4 o'clock. Trouble had befallen Messrs. Applebee and Rose on the way.

◆ ◆ ◆

ON the Stockiemuir Hill, on the Drymen road, the Glasgow Motor Cycle Club held a hill-climbing competition on Saturday last. Mr. J. S. Fulton, the hon. secretary of the club, supervised the contest, Messrs. Farrow and Cree acting as starter and timekeeper respectively. The three prize-winners were:—1, A. Lawrie, 3-h.p. Centaur; 2, John Falconer, 2¾-h.p. Bradbury; 3, A. D. M'Connell, 3-h.p. Automotor.

◆ ◆ ◆

THE accompanying illustration depicts the 3-h.p. ladies' motor-bicycle recently introduced by the Singer Cycle Company, Limited. The ease of control is a conspicuous feature of the machine; both throttle and exhaust are actuated from the left handle, and one turn of the wrist will either increase or decrease the pace. Owing to the position of the engine, the rider's skirt is kept absolutely clean, and she can present herself at a friend's house on the termination of a ride scarcely more dusty than if she had been riding an ordinary safety bicycle. The transmission is by chain, well covered in a gear case. Mrs. Kennard writes that she has ridden this machine with much

interest and pleasure, and has found it an admirable hill climber and very fast. She adds that "the horse power is somewhat high for a novice, who would be well advised to content herself with a 2-h.p. engine for making her debut."

THE Automobile Club of Cleveland, U.S.A., has decided to send a circular to each registered automobile owner in the city, quoting the State law and city ordinance in regard to the use of motor-cars on the public highways, and calling upon their owners to comply with the law at all times and to co-operate with the club in suppressing furious driving.

The International Motor-Bicycle Race.—A View on the Course at Foret-Le-Roi.

IT is proposed to organise a motor reliability trial from Sydney to Melbourne, a distance of close upon 600 miles. Should sufficient support be forthcoming from the motorists of Melbourne and Sydney, the run will most likely be held towards the end of February next, and will probably be divided into three classes, viz., cars, voiturettes, and motor-cycles. The route would be divided into three sections—Sydney to Yass (191 miles), the first day; Yass to Albury (186 miles), second day; and Albury to Melbourne (196 miles), third day.

CORRESPONDENCE.

MOTORING IN CANADA.

To the Editor of *The Motor-Car Journal.*

Sir,—A few lines on automobile doings in the far West of the great Dominion of Canada may be of interest to your readers and tend to show the steady progress which the horseless vehicle is making in every quarter of the globe. The part of Canada of which Winnipeg is the principal city, and the centre between the East and the extreme West, was twenty years ago practically undeveloped, the present large and well-ordered city being represented by a village of some 1,000 inhabitants, which to-day has altered to a total population of 82,000, an average increase of four thousand a year. Some two or three years ago motoring was confined to one gentleman, who is the secretary of the present Winnipeg Automobile Club, which was formed in April of the current year and now numbers over fifty members, the progress of the club from the commencement having been very gratifying. A good number of chauffeurs with a racing bent are numbered in its ranks, and it is intended to make Winnipeg take the lead in Canada in arranging motor racing events, endurance trials, etc., on similar lines to those followed in the arrangement of these contests in the old country. At the recently concluded Dominion Exhibition, which was held in Winnipeg for the first time this year, a series of races were arranged by the writer, and aroused considerable interest, a great crowd being present each evening when the races were held. Although there were no racing cars in the city, some very good times were accomplished by the local drivers, the best performance being that of J. K. McCullock on an ordinary 12-h.p. Ford touring car, he covering five miles in 8 min. 20 sec. on a half-mile track, which was practically unbanked. This taste of speed driving has resulted in the arrangement of an endurance test, in the shape of a race to Stonewall and back, a distance of between sixty and seventy miles, and a trophy has been promised by a well-known Canadian firm. It is proposed to make this an annual event open to all comers, the cup to be held by the winner for one year.

There is plenty of scope for automobilists in the West of Canada, and a great future is open to a manufacturer who has business enterprise enough to commence the manufacture of automobiles in the Dominion of Canada, and thereby save the present heavy duty incurred by cars coming from the United States or other countries.—Yours truly,

Winnipeg. A. Emmett.

ARE MOTOR-CAR WHEELS STRONG ENOUGH LATERALLY?

To the Editor of *The Motor-Car Journal.*

Sir,—Having regard to the recent accidents, fatal and otherwise, due to the lateral instability of motor-car wheels, it is questionable whether the present pattern "artillery" wheels, now so popular, are sufficiently strong enough to withstand the severe lateral strains they are subject to, particularly on heavy and high-powered vehicles. The front steering wheels especially are called upon to bear enormous lateral strains in rounding a curve at high speeds, as they have to take the whole thrust in a direction in which all wheels are more or less weak. The present system of manufacture, in taking the spokes vertically direct from the rim centre to the centre of the hub, may be more or less satisfactory in the case of the rear driving wheels, where the strains are mainly vertical and parallel to the driving power, but in the front steering wheels it would appear to be a wiser policy on the part of manufacturers to copy the principles of the bicycle wire wheel a little more by taking the spokes alternately at a slight angle by "splaying" the spokes from the rim to a wider hub, and thus give the wheels considerably more lateral stability.

It is obvious that in all four-wheeled vehicles, mechanically propelled, severe lateral strains are imposed on the wheels. Even the rear wheels of a car are subject to these owing to the constant "sag" and side-to-side swinging movements of the car body and framework on the springs, set up and due to the inequalities of the road surface and the steering of the car, but the lateral strains of the rear wheels are infinitesimal compared with what the front steering wheels have to withstand in this respect, and yet how many cars do we see, especially of the light voiturette type and the cheaper varieties, where the whole of the four wheels are identical in design, build and strength, which is surely a mistake.

Anyone has only to study a broken-up motor-car front wheel to have it forcibly brought home to him how unstable and weak they are, and the wonder is that there are not more accidents due to their failure to stand the strains, though they are numerous enough. Let any driver watch how the two steering wheels behave in running over a rough macadam road, and he will realise the enormous strains thrown on the hub centres in keeping the wheels straight. Some wheels seem to crush up like egg shells directly any unusual side strain is thrown upon them, such as running at an angle on to a kerbstone or high footpath or bank, and numerous accidents have occurred owing to wheels collapsing in turning a corner at high speeds.

It will be remembered that a serious accident happened in the Isle of Man, on Snaefell mountain, to a touring car during the elimination trials, owing to a wheel collapsing in turning a corner. The front wheels of Mr. Earp's car on the occasion of his memorable accident at Douglas broke into matchwood on meeting the edge of the footpath at an angle of about forty degrees, and the writer remembers, when sadly examining them as they lay smashed to splinters near the wrecked car, wondering how they had safely gone through the severe strains put upon them two days before in the 255 miles trials—they seemed to have been built so frail. Then the arguments as to lateral weakness have been still further borne out by the recent tragic accident to Sir William Rattigan, M.P., near Biggleswade, owing to his car wheel collapsing in turning a corner even at a slow speed. Such accidents prove that there is something radically wrong in the present construction of the "artillery" pattern wheels now so popular, and makers will be well advised in returning to the principles of the bicycle wheel in theory, at any rate, if not in the material used.

The writer recently interviewed a manufacturer who confines his attention solely to building motor-car wheels of the "artillery" pattern. While admitting that the spokes would be better alternately "splayed" from the rims to wider hubs, he contended that a properly-built wheel of real "hickory" wood spokes ought to stand any strain that could be put upon it. He stated, however, that in the desire for cheaper wheels many makers used "greenheart" wood for the spokes instead of "hickory," with the result that in case of accident the greenheart spokes snapped off like carrots, whereas real hickory spokes were almost impossible to be broken transversely. It is, therefore, of importance to insist on real hickory wheels being fitted to all cars. A firm of engineers at Blackburn have recently brought out a new wheel in which the spokes are of steel tubes swaged to a special shape at the axle ends, so that they all bind upon one another circumferentially and are then clamped together by two specially shaped hub flanges. The spokes are all in equal tension and are unbreakable and cannot collapse, while the appearance is similar to the ordinary wooden pattern; there is no shrinkage of the spokes, as in wood, causing unequal tension.

To sum up the whole matter, the writer is of opinion that motor-car wheels can be considerably improved in design and lateral stability, and that front steering wheels should be built much stronger laterally than the rear wheels. The opinion of other motorists on this important subject would be interesting; the writer, however, simply gives his impressions from his own experience and observations, and has based his notions on examination of broken car wheels which have frequently come under his personal notice.—Yours truly,

J. T. Ward.

HOTEL CHARGES.

To the Editor of *The Motor-Car Journal.*

Sir,—The letter in the *Journal* of the 10th inst. reminds me of our touring trip through the New Forest. We landed one evening at Horsham, the car was put up in the yard of the "King's Head," where a very large signboard proclaimed, in big letters, "Head-quarters of the A.C.G.B.I." Being of humble mind, we did not put up there ourselves. Next morning in the hotel yard, in consequence of such cobblestones as I never saw before, my steering gear broke down on starting. The repairs were very reasonably done by Messrs. Jackson Brothers, who I would wish remembered when the A.C.G.B.I. appoint official repairers in Horsham. Before starting I ordered three cans of Pratt's petrol from the hotel yard, but, at the charge of 3s., refused two of them. These two were supplied by Messrs. Jackson Bros. at 1s. 2d. per gallon, viz., 2s. 4d. per can, thus saving the overcharge at the head-quarters of the A.C.G.B.I. of 1s. 4d. on the two cans refused, and they were delivered to my car in the yard, as, without the steering-gear, I was unable to move.—Yours truly,

Motor Union, D 372.

THE PORTMARNOCK MEET.

To the Editor of *The Motor-Car Journal.*

Sir,—With reference to the disqualification of Mr. A. Govan in class G of the motor races held at Portmarnock by the Irish Automobile Club, Mr. Alec Govan was disqualified owing to an objection lodged by Mr. A. Rawlinson for not carrying passengers weighing in all forty stone. There was no mention in either the programme or the entry form of the actual weight required to be carried. Neither were the passengers required to be weighed before or after the race, nor were they asked in this particular instance to return the gross weight. When the officials were asked about this they merely stated that they were running the races under the rules of the English Club, and that the rules required a gross weight of forty stone. Now last year the Irish Club ran their races under the same rules, and yet they ran them without any passengers beyond the driver. In face of the club changing this year surely it would be an easy matter to put down the actual weight required to be carried.

I fear, however, that trade influence has a good deal to say to these unfortunate frivolous objections. Mr. Govan won his heat by 300 or 400 yards and in much shorter time than any other heat, and it was self-evident that the race was at the mercy of the Argyll for the final. I hold that in view of the fact that the officials omitted to put down in the programme the gross weight required to be carried as a *condition* of this particular race the judges' decision was hasty and not based on reason. Mr. Govan, as well as many others, attended this meeting at great inconvenience and expense to themselves. It would be well if

Digitized by Google

sport-promoting clubs were to take more trouble in publishing conditions and thus obviate hasty decisions.—Yours truly,

W. R. McTaggart.

TAIL LAMP TROUBLES.

To the Editor of *The Motor-Car Journal.*

Sir,—I cannot quite reconcile "B 453's" letter with my knowledge of electricity. He states that with a four volt accumulator he uses ·08 amperes with his lamp. That is to say, ·32 watts. Now I understand that electric lamps use four watts to the candle power. Apparently, therefore, "B 453" illuminates his back number plate with about one-twelfth of a candle power. I should doubt whether the law would consider this strong enough to "render easily distinguishable every letter or figure, etc." If this device proves satisfactory and the data given by "B 453" are correct, then the lampmaker should reap a well-deserved fortune for manufacturing a lamp with such extraordinary illuminating powers.—Yours truly,

A. T.

A SUGGESTED COMPETITION.

To the Editor of *The Motor-Car Journal.*

Sir,—During the period while the automobilist is debarred from satisfying the elementary sporting instinct of humanity—to *get there first*—competitions flourish, and nearly every desirable quality in a car—reliability, economy, power—to observe the law, has been the subject of distinct and separate test. But, notwithstanding improvement, now and then—more then than now we may hope—a little, just a little, trifling adjustment is necessary. And cars vary exceedingly in the facility with which such adjustments are effected, as was borne in upon me recently when lining up some bearings in two cars. In one, the removal of half-a-dozen bolts was all that was necessary; in the other, twenty-eight bolts had to come out, and involved the search for some box spanners and ratchet brace especially designed for getting at out-of-the-way corners. Of course, the car that wants no adjustment is best, and, fortunately, to judge by the catalogues, there are many of them; but for the others, a repair competition in which the drivers should have to get at, remove, and replace certain specified parts, or rectify some supposed mishap—as, for instance, fired connecting-rod bearing, obstruction in petrol supply, broken valve spring, slipping clutch, damaged pump, foul valves, etc.—would bring out some important points in design that do not always receive the attention they should.—Yours truly,

Motor Mechanic.

THE CARE OF ACCUMULATORS.

To the Editor of *The Motor-Car Journal.*

Sir,—I should be obliged if you or any reader of the *Journal* would give me some hints as to how an accumulator should be treated which is not in constant use. I have two accumulators, and they often have to stand over several months without being used. Would it be best to partially discharge these and then recharge them? I understand it is injurious to accumulators to let them stand without being charged and discharged. I should also like to know whether accumulators should be entirely discharged before emptying the acid in order to clean them. If so, how should they be discharged?—Yours truly,

Willebrook.

[An accumulator which is to stand idle can be treated in two ways, either of which can be selected to suit the convenience of the user. It should either be thoroughly discharged or kept thoroughly well charged, in which latter case it is, of course, always ready for use. In the first instance, proceed as follows:—Thoroughly discharge the accumulator by connecting it to a 4-volt lamp, or a coil of iron wire until it has discharged down to 1⅘ volts per cell, or 3·5 volts for a 4-volt set. Immediately after discharge, empty the acid out, and rinse the cells with water until they are quite free from acid in the plates or in the cell. Then drain it out and thoroughly dry the terminals and top of the case. Carefully vaseline the terminals and rubber bands to keep the latter soft, and put away in a card box to prevent dust settling on the top. In the second instance, charge up the accumulator so that it can be said to be thoroughly well charged. If there is a connecting wire joining the two cells together at the terminals, take this away, as it leaves the two cells with their pressure divided. See that the top of the cell is very clean and vaseline the terminals and rubbers; take out the vent corks, as they cause spraying. After three months, charge up again, if the accumulator appears to have lost its voltage. After an accumulator has been once properly formed, it is not necessary to charge and discharge it when standing, provided it has received a good charge before standing. The easiest method of discharging is by connecting a lamp up to the terminals and leaving it until quite out.

TYRES.

To the Editor of *The Motor-Car Journal.*

Sir,—I have recently taken to motoring, and last July had delivered to my order a 12-h.p. Darracq. I have not yet mastered all the technicalities of the engine, but that portion of the car is eminently satisfactory, and gives no trouble whatever, but I think I can justify the claim to a past-mastership in the matter of wearing out tyres. The car is fitted with Clincher Michelin, size 800 by 85, and in a run of about 600 miles they were reduced to what was practically inflated ragbags, then the puncture fiend came on the scene, and it was with considerable difficulty that I got home. A visit to the Liverpool agents of the company elicited the consoling information that "it was a matter of luck," with a recommendation to purchase new tyres for the hind wheels. I should be obliged if any motoring experts can inform me if there are any other "matters of luck" connected with the sport, which may prove equally as expensive, as I am very anxious to know the worst.—Yours truly,

John Anson'a.

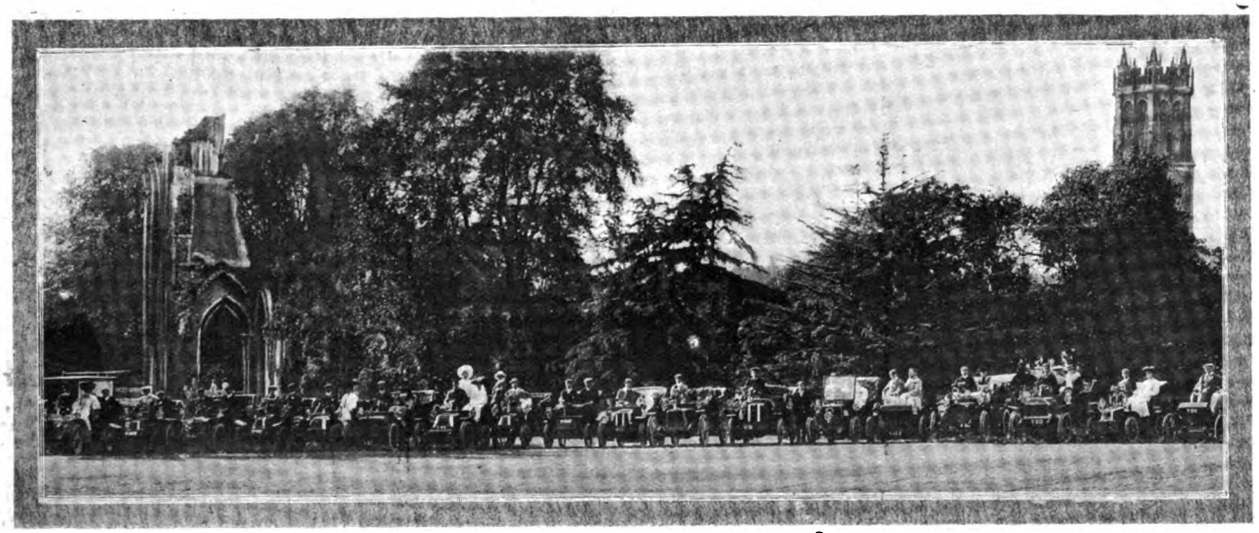

Photo by] The Meet of the Somerstshire Club at G'as'onbury Abbey. (*See page* 633.) *[Monlague Cooper.*

ENGINE-STARTING TROUBLES.

To the Editor of *The Motor-Car Journal.*

Sir,—I can sympathise with Mr. R. Hannen *re* his trouble in starting up, as I have experienced the same trouble, which I found due to carburation, viz., a great enough suction cannot be got by turning the handle to draw enough petrol into the cylinders, not even with the airways closed.

I advise him to do as I do. Carry a small squirt can of the flat type, at about 1s. 6d., and always keep it full and on the car, and when he wants to start up, inject into each cylinder, through compression taps, just so much as one nip of the squirt will ejeet, close the taps, and then turn the handle. This should start the motor all right.—Yours truly,

R. H. Antill.

RECKLESS DRIVING.

To the Editor of *The Motor-Car Journal.*

Sir,—The practice of doing everything possible to avoid frightening horses and causing annoyance to horse drivers is one that should be encouraged. Motor-cars are still in the minority on the road, and, though they certainly have equal rights with other users of the highway, and the automobilist should not permit himself to be imposed upon, still it is the best policy to make as many friends as possible, for the good of motoring generally. The old saw concerning prevention and cure si

Digitized by Google

exceedingly applicable to meetings between horses and motor-cars. If you are a frequent traveller over the same roads you will soon see the result of your good work in this direction. One thing that should be avoided as much as possible is the continuous use of the horn. Use it when necessary, but do not be lavish in your solos, for it is a species of music that few are capable of appreciating.—Yours truly,

JOG ALONG.

BELT TRANSMISSION.

TO THE EDITOR OF *The Motor-Car Journal*.

SIR,—It would appear from articles in the press on the recent failures in the light car trials, that the moderate priced car for the business man or the man of moderate means is a long way off yet. I am one with your other correspondents in believing that a simple efficient belt-driven car, minus the weak points of both gear and previous belt systems will be found to be the solution of the problem. From the remarks already made in the letters that have appeared in your *Journal*, this does not seem very remote either, nearly all the defects having been intelligently dealt with in recommendations for their abolition. Also I am pleased to see that trials are being made by inventors, and manufacturers would do well to go thoroughly into the light car question; the market for a simple, inexpensive, reliable vehicle would be immense.—Yours truly,

INTERESTED.

SOLID TYRES

TO THE EDITOR OF *The Motor-Car Journal*.

SIR,—I have a 5-h.p. Oldsmobile motor-car, and I should be greatly indebted to any reader of the *Journal*, who has had the required experience, for advice as to whether these little cars can stand having

The Military Manœuvres.—General French and Staff at Clacton
Photo by *Mr. Herbert Smith.*

some form of solid tyre fitted to the rear wheels, and also if there would be much loss of speed and hill-climbing power by doing so.—Yours truly,

M. B.

REPAIRS AT BRISTOL.

TO THE EDITOR OF *The Motor-Car Journal*.

SIR,—There is plenty of room in Bristol for a reliable motor repairer. The city and suburbs number nearly 400,000 people, and an automobile club is at last about to be formed there.. All riders from John o' Groat's to Land's End pass through Bristol, and the best position for a repairer would be found somewhere on the route through Bishopston, Cheltenham Road, Stokes Croft and Victoria Street.—Yours truly,

S. C. G.

TAIL LAMPS.

TO THE EDITOR OF *The Motor-Car Journal*.

SIR,—In answer to "Rosthern" in the *Journal* of the 3rd inst., I had some trouble with tail lights and tried all makes, but found they would not stand the vibration, until I came across a lamp made by Lucas, Ltd., and was induced to purchase one at a cost of something like a guinea, and from that day to this—namely, last November to now—I have driven car about 7,000 miles, and have never removed lamp except to trim and clean it, and have never had any trouble with it.—Yours truly,

SATISFIED ONE.

SILENT CARS.

TO THE EDITOR OF *The Motor-Car Journal*.

SIR,—I read your article on "Silent Cars" with interest. I have a rather noisy car, and would—and I expect many others similarly circumstanced would—willingly suppress the noise if it could be done without sacrificing power. Hitherto I thought that muffling the exhaust caused an appreciable loss of power.

I am more hopeful since you state that "in minimising noise, power is conserved and used in propelling the vehicle instead of being wasted." If any of your readers will kindly put me on the right track I shall feel grateful, and, providing the cost is not prohibitive, I guarantee there shall not be a more peaceful car than mine.—Yours truly,

A. G. J.

NAIL CATCHERS.

TO THE EDITOR OF *The Motor-Car Journal*.

SIR,—I have not tried any "special" nail catcher advertised, as they are so very expensive, so I do not know whether they are effective or not. What I have done, and done with undoubted success, is to fix an ordinary chain on my wings to hang over the wheels and so prevent flints and nails from cutting the tyre. It is worth while to try the experiment, as chains are cheap. I have made use of my wing guard stay to fix a chain. I find this very effective, and furthermore the tyre is not worn in any way, although the chain may often want renewal.—Yours truly,

H. HUGHES.

STEAM CARS.

TO THE EDITOR OF *The Motor-Car Journal*.

SIR,—I think many prospective motorists, also many petrol car owners who are considering the purchase of a new car, cannot but be struck with the increasing interest in the steam car industry, which is evinced by the correspondence in the motor press and also the increasing number of steam cars on the roads. Such being the case, it would be very interesting to know how such cars behave under trying conditions as compared with petrol cars, what are the more vulnerable portions of their mechanism, and generally what are the most usual causes of a temporary roadside halt I am alluding in this letter to such well-known steamers as the White, Miesse, or the Serpollet. Of these the Miesse appears to be by far the simplest, an advantage for which it may possibly suffer in other respects, but that is not the point at issue, and except for a little care in regulating the fire so as not to burn out the tubes, I should think the advantages gained by eliminating all automatic regulators must more than compensate for the slight extra trouble involved. However, to return, the Miesse has one main burner, two water pumps and one air pump, and it is difficult to see how these four pieces of apparatus, three at least of which are to be found in many cases on that most reliable machine, the modern locomotive, can be as liable to derangment as coils, clutches, carburettors, ignition systems, and possibly gear boxes, all of which are eliminated. Still, where one has no practical experience it is unwise to draw conclusions, and I think if some of your readers who use these or similar cars could be induced to write their experiences showing clearly the ills to which the steam car is heir, they would be conferring a great boon on a large class of motorists which admire the steam car's silent easy running, but fears to abandon the evils of the petrol car which it knows, for those of the steamer which it wots not of.—Yours truly,

DOUBTFUL.

TO THE EDITOR OF *The Motor-Car Journal*.

SIR,—I have read in your *Journal* of the 10th a letter signed "Wise Man."

I would like to point out to this gentleman that there are other steam cars on the market besides the one he names, and that, just because he has had bad luck (probably due to ignorance) as he says he scorched his boiler, which to my thinking ought never to happen to a man who is careful and blessed with a little common sense, he at once condemns the steam car. Perhaps it may interest this gentleman to know I have driven my car, certainly of a different make to the one he names, but selling under £200, to carry four, over several thousand miles, and except for occasional tyre troubles have gone there and back every time. Of course I always take care to have water in my boiler.—Your truly,

UNBIASSED.

TO THE EDITOR OF *The Motor-Car Journal*.

SIR,—The troubles of a "Wiser Man" with his Locomobile were, I think, entirely his own fault. The pumps fitted to this car are amply large enough, and the failure was most likely owing to the check valves being out of order. If so, it did not matter how large the bore of the pump, the water gauge not showing the proper level was due to sediment getting into the bottom pipes, and when kept properly clean there is no trouble.

I have driven my car many miles and never had any trouble with the pump or water gauge. Every time I stopped I blew off a little water, keeping everything clear. I have not had any experience with paraffin burners so cannot say about them.

I have had many pleasant rides on my Locomobile, and just lately went with a friend on his Weston from London to Canterbury, through Chatham, and back home *via* Maidstone, and nothing better could be desired by any reasonable person, not the slightest trouble all the way

Digitized by Google

Such a letter as "Wiser Man's" will create a prejudice against a type of car that in the hands of a careful user will give every satisfaction, as many readers will not consider that this particular car was in the hands of a gentleman who seems to possess hardly enough mechanical ability to take charge of a mangle.—Yours truly,

W. T. WARNE.

TO THE EDITOR OF *The Motor-Car Journal.*

SIR,—I have just read "A Wiser Man's" letter in the *Journal* of the 10th inst. Your correspondent seems to have bought a "pig in a poke" with a vengeance, but he surely did not expect that a £275 car would be sold for £85 unless there was some need to spend money on it. Had he been wise enough to pay a competent man to examine and report on the car he would probably have been saved much annoyance and loss—he would most likely have found that he had to spend some £50 in repairs before he could hope to run the car, but he would have had some fun out of it, anyway. The mere fact of "drinking" paraffin, and only doing twenty-one miles in four hours, and requiring also hard labour at the hand pump shows that engines and boiler must have been sadly in need of repairs when he bought it, hence the "cheap" price. If he buys any car, steam or petrol, in such a haphazard way he is likely to buy trouble as well.

How can he fairly blame the car for burning his boiler? Common sense would dictate to anyone to make allowance for the car not being on the level. I am afraid if "A Wiser Man" were to burn a boiler in a steam-boat because she was not on even keel and the gauge glasses deceived him, that the Board of Trade would not accept such an excuse.

I hold no brief for steam cars, but I do like to see fair play, and don't like to hear a man blame a machine for his own stupidity; it reminds me of the story of the Irish engineer, who tried to put the bolts in a crank-pin bearing upside down, and then swore that the smith had put the heads on the wrong ends.—Yours truly,

C. S. DREWRY.

TO THE EDITOR OF *The Motor-Car Journal.*

SIR,—Being an old subscriber to the *Journal*, I have watched the discussion therein on the merits and demerits of steam carriages. On the one hand I find that the experience of some motorists is such as to enable them to speak well of steam cars, whilst on the other hand others appear to have had an unfortunate experience with them, and in relating that experience some of their remarks are such as to cause many non-technical men to believe it to be impossible to construct a sound steam carriage. I admit that some of the American steam cars are particularly faulty, the chief evil being the bad construction of the boiler. Most of the vertical firetube boilers are too short in height, too thin in the tube plates, and the vertical shell too thin. The fire tubes are too narrow in diameter, and too close together. With these thin tube plates, together with the small quantity of water contained in the boiler, even when at its highest level, the tubes are easily set leaking. Furthermore, with thin plates, aforesaid, the riveted seams will not keep steam and water-tight, but soon commence leaking. A height of 14in. between the top and bottom tube plate is much too little, tubes ½ inch external diameter are too narrow, and boiler plates only $\frac{3}{16}$ inch thick are much too thin, yet the above dimensions of boiler are found in connection with some of the American steam cars. In vertical firetube boilers it is important that tubes should always be surrounded by a good depth of water, which does much to prevent leakages, also makes steam faster. A steam boiler ought not to be put out of sight under the driver's seat. It ought to be fixed in front of the driver, with its steam and water gauges screwed on it, so as to be constantly in view of the driver. A height of twenty-four inches between the top and bottom tube plate, with tubes one inch external diameter, and not closer together at any point than $\frac{3}{16}$ of an inch, with the vertical shell $\frac{3}{8}$ of an inch thick, and tube plates each ½ inch thick, would do well for a boiler in a motor-car carrying five or six persons. The water round the tubes should never be less than twelve or thirteen inches deep, when at its lowest level, with an additional five or six inches depth for variation in the glass gauge, and the remainder depth of space for steam, making twenty-four inches depth altogether between the top and bottom tube plates. The smoke box on the top of the boiler, together with the stand for the burners underneath, would add a little more to the height of the boiler. It could be welded in the vertical seam, the bottom tube plate could also be welded in, and the top tube plate riveted in, or both tube plates welded in, the holes for the tubes being bored afterwards. Smoke box, and stand for burners, each put on with screws. This would be a substantial boiler, and not give trouble.

The wire-spoked wheels and the frame of some American steam cars are too fragile for a substantial car. A few steam carriages were made in England years ago, and successfully and economically worked until the law prohibited the use of self-propelling carriages. One steamer, amongst others, has conveyed four persons at a cost of one penny per mile, including toll bar charges, making one farthing per mile for each person. Steam acts as a lubricant for the cylinders and pistons, limiting the heat of cylinders, etc., to the temperature of the steam itself, thus preserving them, and thereby giving the engine a longer life than the petrol explosion engine. In case of a worthless boiler, then get a new one properly constructed. A steam carriage of good design, well and strongly made throughout, is the best thing on the road.—Yours truly,

MECHANICAL ENGINEER.

BOWDEN WIRES.

TO THE EDITOR OF *The Motor-Car Journal.*

SIR,—In the report of the judges on Small Cars occurs the following paragraph:—

"Bowden wires are used in a few cases for throttle and spark connections, and proved unsuitable." This specific mention, derogatory as it is, calls for explanation. If the judges had said they proved unsuitable because they were improperly fitted, I could have understood it, but when it is known that the Bowden wire mechanism is universally used with pronounced success in numerous mechanical operations, it is late in the day to condemn it without qualification. One might think that the fact that over a million bicycle brakes, operated by Bowden wire mechanism, have been made and sold, is some evidence of its suitability for such operations, but if further proof is required, its common use on motor-cycles, the shutters of photographic cameras (demanding the most delicate movement), organ valves, and many similar operations, may be cited.

As for its suitability for motor-car work, I may say that it is largely used in France, and its use increasing. In Germany, after a year's testing, about a dozen firms have adopted it, two of them using it for brake work, as well as for the lighter operations, while the German War Office have adopted it for light and heavy vehicles. For such purposes as the last mentioned we have recently been called upon to produce a combined wire capable of braking ten-ton vehicles, its function being a flexible connection between driver and trailer. Schiemann, of Dresden, inventor of the one-track train of road vehicles, is licensed, and is using the Bowden mechanism freely on his vehicles.

It is regrettable to have to say that in the adoption of this, as in many things, I have found my own country the most conservative. In seeking for an explanation, I have concluded that it is chiefly because up till now British manufacturers have been engaged in making up lost time on the essentials of motor-car construction, and have, therefore, paid little consideration as yet to economies and refinements. The Continental firms have passed the one stage and reached the other. It was not so with the British bicycle trade; they had reached comparative perfection, and so readily embraced the Bowden mechanism.

I may add that my firm was not aware of the Bowden wire mechanism being used by any of the competitors in the light car trials, or that it would be subjected to the criticism of the judges, otherwise care would have been taken to see that it was properly fitted, for our experience is that there is a lamentable lack of knowledge of the functions of the mechanism in engineering circles.

Had the judges added to their criticism the simple words "as fitted," this somewhat lengthy letter need not have been penned.

My firm will at any time be pleased to place a car at the disposal of the judges, or any manufacturer, to demonstrate the suitability of the Bowden mechanism for the purposes indicated.—Yours truly,

JAMES R. NISBET,
Chairman, E. M. Bowden's Patents Syndicate, Limited.

TO THE EDITOR OF *The Motor-Car Journal.*

SIR,—Reading through the report of the judges in the Small Car Trials in the last issue of the *Journal*, I notice that they remark, "Bowden wires are used in a few cases for throttle and spark connections, and proved unsuitable." Why the judges should have gone out of their way to make such an adverse comment on the products of a firm not officially competing in the trials, I quite fail to understand; the more so in that on my own car Bowden wires are used not only for the throttle and spark connections, but also for the carburettor control, and have so far not given me the slightest trouble. I really think that such a condemnatory remark on the part of the judges should not have been made unless accompanied by some explanatory statement.—Yours truly,

A SATISFIED BOWDENITE.

QUERIES RE DE DION CLUTCHES.—Messrs. De Dion-Bouton, Limited, write:—We note the letter signed "A. H. R." in the *Journal* of the 10th inst. under the above heading. If "A. H. R." will bring or send his car or gear to us we shall be pleased to advise him how to remedy the trouble he complains of, providing the car is licensed for use in this country."

"What do you want to sell your car for?"
"Great heavens, man! It's a last month's model."

COACH WORK IN CONNECTION WITH AUTOMOBILES.*

By J. Boarland.

The best horse-drawn vehicles have been produced, but the people want to go faster, unfettered by rail tracks or tramways. The motor-car has come to stop because it goes faster than horses, and humanity desires to go faster. There will, perhaps, be a great many horse-drawn carriages used in the future; some may be displaced by the motor-car, but the number of drawn and propelled vehicles owned by those whom we call carriage people is likely to remain the same, and in addition, there will be the probable demand of the middle classes, who are likely to find something within the reach of their income. There is nothing to alarm the coach maker in this evolution, except he has a rooted conviction that the world is at a standstill. There is money in it and coach makers can cater for it. We have centuries of experience and good taste to help us, and it only remains for us to study how to keep our own work in our own hands. I believe we can do it by keeping up the reputation of British carriage manufacturers for good workmanship and graceful design. It is well known that the most ancient trades turn out the most beautiful objects, and that the origins of these objects are to be found in nature.

We have instinctively copied the parabolic curves of the most graceful of all animals. Coach makers have for generations kept to this ideal. Only once did they depart from it, when some ingenious vandal (probably thinking to cheapen production), discarded sweeps and substituted straight lines. The straight line craze caught on, until it was found that other wood workers, with half the coach maker's experience and none of his good taste, could bolt together a number of straight pieces of wood into the form of a box, mount it upon elliptic springs and call it a dog-cart. This was utility without beauty, and in a few years we had lowered the public desire for good design. The railway carriages on most lines furnish an example of utility without beauty. The production of the motor-car is largely a question of design. The engineer's draughtsman is ready to produce something made up of straight lines and circles. He frames his work strictly in accordance with the parallelogram of forces with a few arcs of circles thrown in. He can construct a frame upon which sheets of metal may be placed, and strips of wood nailed on the latter for mouldings. Stresses are his first consideration, gracefulness comes second. The coach maker, on the other hand, gives the required space in which the occupants may sit comfortably, and sweeps his frame round it in such combinations of curves as are most pleasing to the eye. A piece of work built up with straight lines and perfect arcs has a heavy look. It is not enough to build up something that will do. It ought to answer the purpose and be graceful at the same time. My contentions are:—That the front, back, or angle view of a car ought to be as artistic as the side elevation. That the car ought to be as beautiful in design as it is possible to make it, and that it is essentially the mission of the coach maker to produce a perfectly designed car. The present time may be considered the iron age of the motor-car. Coach makers have been familiar for years with the suggestion to substitute various metals instead of wood for panels. The idea has been condemned again and again only to be reiterated by someone else, and in connection with this new industry it has actually taken shape, and we have not only metal panels, but in some cases metal frames also. The reasons for condemning panels of this description are many. The thin metal shows the battens which are inserted in the frame to give rotundity of appearance. They are easily bent or buckled. In the case of sheet iron they rust through under the trimming, and they add to the vibration of the car. With mild mahogany panels the shape can be neatly rounded and the battens are not seen through them. When properly filled up they give a good foundation for highly finished coach painting. They are stronger than metal panels. The difference in weight between mahogany and sheet iron is trifling. Panels may be shaped in mahogany to such designs as would require templets in the case of metal, and instead of being planted on strips of wood tacked on for mouldings, showing all the nail heads, proper English ash framing can be made without nailheads to be an eyesore, and with very few joints visible. The wings of a motor-car when made of sheet iron are noisy; not even the raised border milled round them stops the drumming sound. The same material should be employed in motor bodies as coach bodies are made from, viz., wood, and I will be glad to hear what the exponents of metal panels have to say in their favour. I believe that the best way to make a carriage perfect is to try to remedy its defects. In this paper I will only point out a few defects, but will not suggest remedies. We will begin at the back of the car, and the door of the tonneau must be voted a nuisance when it does not shut properly. How many coach makers in this Institute would dream of sending out a wagonette with a door which would shut so badly as that of the ordinary armour-plated tonneau motor body? The coach maker who does not forsake the principles of construction used in his trade can make a body the doors of which will open and shut properly. The dash, upon which the bonnet hinges, is often an inferior piece of wood, utterly unfit to carry the number of articles which are bolted upon it, and soon succumbs to the heat from the engine. The steps are poor and badly placed. The engineer takes upon himself the selection and the placing of the steps upon the frame, with the result that they are similar in design and general inconvenience to those upon a locomotive engine. The coach maker has spent many hours of his working life in spacing the height from the ground to the bodies of the carriages which he builds, in considering the proper size and shape of the treads, in booting them and in rendering them safe, so that the carriage user may enter and (what is equally important) may alight in safety, whether in the day or night. The bucket seat has its advantages. It separates the servant from the owner of the car, and it gives support to the sides of the occupant, as well as to his back. The angle of inclination may be right for a car running at thirty miles an hour, and for fast touring cars perhaps it is best, but for the smaller cars and for such persons as do not care to go fast, I am inclined to think that the strained, anxious-looking forward position hardly gives that idea of comfort which one is likely to associate with people who are enjoying their ease and the scenery at the same time. The canopy of the touring car may be made dainty or clumsy, according to the taste of the builder. The curtains, which are hung on rings sliding upon a rod attached to and under the roof, and which are gathered round the standards and tied much after the style of a cotton umbrella, may be effectual in keeping out the storm, but I must intrude my personal opinion and state that they do not look smart. The curtains, which are cut to the rounded shape of the car and are made to hang without wrinkles, give the canopy a more dignified appearance. The sliding wind shield perhaps gives the coach maker most trouble. After he has made it to work properly and fitted so that it will not rattle either when down or under the roof, he finds that the dainty French fasteners which keep it in position are badly fitted in themselves, and make noises when the car is running. Might I appeal to those members who belong to one of the accessory trades to produce a fastener which will not rattle; something which may be turned with the wrist and not with the thumb and finger? It may be said that any fastener which cannot be turned with a

* From a paper read at the Congress of the Institute of British Carriage Manufacturers at Leicester last week.

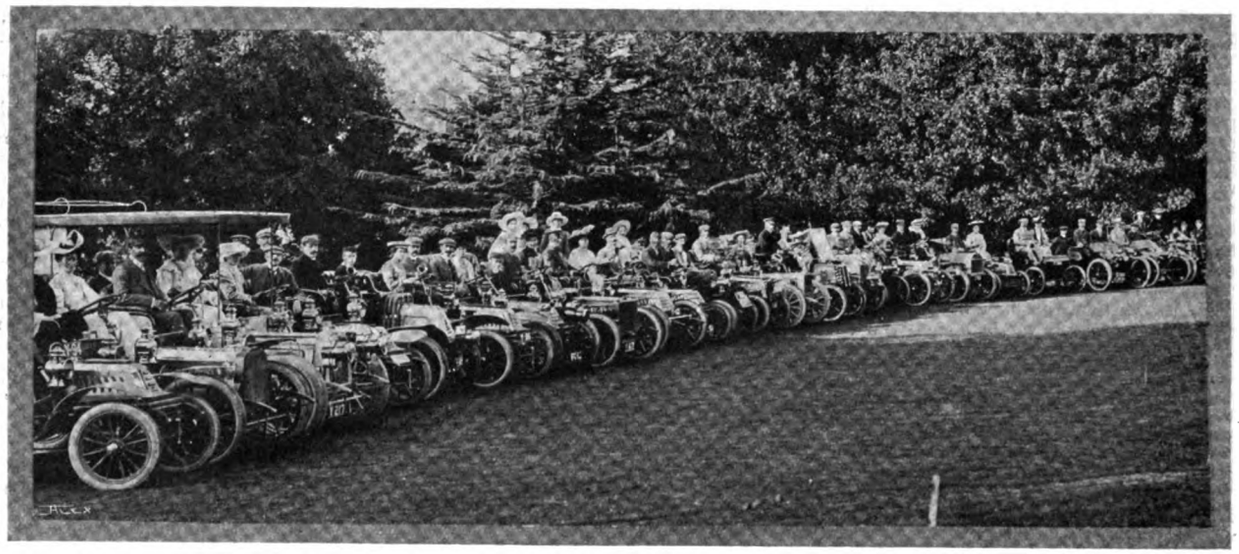

Photo by] The Meet of the Somersetshire Club at Glastonbury Abbey. (See page 633.) *[Montague Cooper.*

Digitized by Google

touch will be condemned. I do not think so. English men and women are strong in the wrist, and it is hardly logical to argue that the ladies and gentlemen who play golf and tennis, and who as boys and girls played with cricket bats and hockey sticks, cannot turn something stronger than the fasteners which are now used for wind shields. With regard to the trimming and painting very little can be said, because the taste of the purchaser has to be consulted. Personally, I think that in a climate where from October till April the sun is but an inconstant visitor, bright warm colours are preferable to deep cold shades. Human nature is paradoxical, for we see the carriage users who in times gone by complained of the slightest noise in their carriages now taking no notice of such things when driving in motor-cars. Motoring is new, but when the novelty has somewhat worn off it is not improbable that noisy doors and windows, and the various things which were found fault with in horse drawn carriages, will be commented upon by the users of motor-cars. When that time comes, some of the attention which is now centred upon the engine will be diverted to the body, and a good body will be considered as essential to a motor-car as a good engine now is. To sum up, the British coach maker in building motor bodies should keep to his old ideals of good workmanship and graceful designs, of utility coupled with beauty. He should model them on the shapes used so long in horse drawn carriages and build them of similar materials.

CLUBS AND ASSOCIATIONS.

LINCOLNSHIRE.

On Thursday last week the members of the Lincolnshire Automobile Club were invited to Boothby Pagnell, near Grantham, to witness some motor competitions which had been promoted by the Hon. Maurice and Mrs. Gifford. Delightful weather favoured the event, and close upon 30 cars, which carried nearly 100 passengers, drove over to the meet. Two amusing competitions were arranged. The first was a driving contest, in which a road lined out with string and stakes in a field, and very tortuous in outline, had to be negotiated. On the way a police trap was arranged, and a mechanical gentleman in "blue"—deftly manipulated—popped out of his hiding-place every time a car approached. Just beyond this there was an obstruction, a child, represented by a huge doll, being thrown across the course. This was done with a view of testing the brakes, the cars having to be brought to a dead stop to avoid collision with the child, and then proceed to the finishing line. The competition was judged by marks, the handicap being based on the time, stopping, and dodging the policeman. The wheel base was also taken into consideration. At least 200 people watched the proceedings, and the efforts of the motorists to get by the police trap caused immense fun. Eight cars were entered for the competition, and when the adjustments had been made it transpired that the following was the order of merit :—

	Marks.
1. Capt. Cole, J.P. (Roxholm), 12-h.p. Durkopp ...	17½
2. Major Goddard (Lincoln), 12-h.p. Richardson ...	22
3. Mr. C. Holland (Boston), Baby Peugeot	26½
4. Mr. R. M. Wright (Lincoln), 8-h.p. De Dion	42½
5. Dr. Hancock Steil (Colsterworth), 7½-h.p. Wolseley ...	43
6. Capt. Lyall (Grantham), 7-h.p. Panhard	48½
7. Dr. Mason (Boston), Baby Peugeot	49½
8. Mr. C. Nelson (Lincoln), 4-h.p. De Dion	62½

To the winner (Capt. Cole) a handsome set of silver apostle teaspoons and sugar tongs was presented. Dr. Gilpin officiated as starter and timekeeper, and Mr. Cyril Greenall was judge. The small cars had an infinitely better chance of negotiating the difficult turning points, and the larger cars received an allowance on this account. When this competition was over an *al fresco* tea was served to the visitors, after which there was a surprise competition, the Hon. Maurice Gifford offering a special prize to the owner of the car whose engine was found to be in the best cared for condition. This competition was sprung upon the motorists so suddenly that there was no possible opportunity of one being able to secure an advantage over the other; in fact, many of the motorists did not know of it until the "bonnets" were off and the judging was in actual progress. Where a car had a chauffeur to look after it, marks were deducted. Capt. J. A. Cole, and a motor expert from Grantham (Mr. J. Smith) were deputed to make the inspection and report. There were several very well-kept engines, and it was very soon seen that the prize lay between Mr. J. D. Sandars' Peugeot and Mr. C. Greenall's Panhard. After a further examination the first named gained the award.

SOMERSETSHIRE.

The famous Benedictine Abbey at Glastonbury, traditionally said to have been founded by Joseph of Arimathea in A.D. 63, visited by St. Patrick in 433, and by him formed into a regular monastic community, was gradually, under succeeding Abbots, extended and adorned until in the reign of King Henry 8th, under Cardinal Wolsey, it had attained the position of the handsomest and wealthiest establishment of the kind in the kingdom. On November 14th, 1539, Abbot Whiting (the last Abbot) after a mock trial was hanged at Wells, and the work of spoliation commenced. Little now remains of the old grandeur beyond the walls. The entire property was purchased some years ago by Mr. James Austin, who has spent considerable sums of money in preserving and collecting all the scattered fragments that can be found.

On Friday of last week, by the kind invitation of this gentleman, the members of the Somersetshire Automobile Club assembled in the Abbey Grounds for a garden party. A magnificent day tempted motorists from all parts of the county, and all were most hospitably welcomed. Sweet music was discoursed by the Glastonbury Band, and with the setting sun the members dispersed to their homes.

The Lincolnshire Club's Competition.—Mr. R. M. Wright on his 8-h.p. De Dion in the Obstacle Race.

KENT AND EAST SURREY.

The last meet of the season of the Kent Automobile Club took place at East Grinstead, on Saturday, where the members of the Club were invited and entertained by the East Surrey Automobile Club. Fine weather made the united clubs' meet a most enjoyable event. Mr. David J. Barry, the hon. sec. of the East Surrey Club, was one of the first to arrive and received the members of the club, among whom were Dr. Charles Firth, Mr. and Mrs. Granville Kenyon, Mr. W. Willis, Mr. Edward Latter, Mr. Owen Firth, Mr. and Mrs. Bernard, Arnold, Mr. Cosh, Mr. Madeley, Mr. and Mrs. Symonds, Mr. and Mrs. Cornell, and several others.

BBEA

SHEFFIELD.

On Saturday 40 members and friends, on fourteen cars and three motor-cycles, went to the Sheffield Club meet at Ashopton, and thence to Birchinlee, taking advantage of the permission accorded by Ald. T. R. Gainsford, the chairman of the Derwent Water Board, to go over the new water-works. From Ashopton the road is not an ideal one for motor vehicles. In the first mile a 200 yards stretch of newly metalled road was encountered. Then there came several short, steep hills, which tried the capacities of both vehicles and drivers. On arriving at the "village" (which, by the way, is quite a town) the motorists were met by one of the resident officials, Mr. S. G. Hallett, and conducted over the works. Amongst the cars present were :—Mr. E. F. Coupe, 24-h.p. Darracq; Mr. C. D. Leng, 10-h.p. White steamer; Mr. Ben Hind, 11-h.p. Clement; Mr. C. Burnly, 6-h.p. La Plata; Mr. Jos. Barber, 7-h.p. Belsize; Mr. W. Watts, 6-h.p. Humber;

Digitized by Google

Mr. J. F. Pickering, 10-h.p. Norfolk; Mr. Turton Chatterton, 6-h.p. De Dion; Mr. H. Beesley, 6-h.p. Wolseley; Mr. A. J. Blyde, 3½-h.p. De Dion; Mr. E. H. Hill, 12-h.p. Darracq; Mr. E. W. Hatfield, 6-h.p. Regal; Mr. J. R. Wade, 10-h.p. Norfolk; Mr. Hudson Lygo, 10-h.p. Cavendish; Mr. E. Ott, 2½-h.p. Humber motor-cycle; Mr. F. W. Oates, 2¾-h.p. De Dion; and the hon. secretary, Mr. F. B. Cawood, 2¼-h.p. M.C. tricycle.

TYRES ON AUTOMOBILES.

BEFORE the Brentford magistrates, on Monday, John Cronk, of West Ealing, was summoned for causing to be travelled a light motor with improper tyres, contrary to the Motor Car Act of 1904. The motor in question was of the Wallis and Stevens type, and the wheels were ribbed. The complaint was laid under the clause of the Act which provides that all light motors shall have flat surfaces to the wheels. For the defence, it was contended that the surface resting on the roadway was perfectly flat, and that the definition of the terms of the Act was to provide against the use of pyramids and bolts, spikes, &c., such as were used in traction engines. Mr. Shrapnel Smith, who said he had studied this type of machine for six years, stated that this particular machine met the requirements of the Act by having more than 4 in. of even surface on the roadway. The question had been raised before the various commissions on light motor transport, and new regulations were being drafted or were already in print. It was impossible mechanically to build wheels of this class flat, because of the tyre expanding as a result of impact with the road, and the whole wheel was put out. Many thousands of pounds had been expended in the manufacture of these light motors, and he himself had had charge of the Liverpool trials and had given evidence before commissions on the subject. The magistrates decided that the ribs on the wheels went beyond the law, and fined the owner £1 and the driver 2s. 6d. For a technical offence in drawing two vehicles instead of one behind a light motor, contrary to the Act, the same defendant was fined £5 and costs.

A MOTOR-CAR ACCIDENT.

THE inquest on the body of John Hales, of Coventry, who was killed in a motor accident at Kenilworth on August 31st, has been concluded.

Thomas Stevens, the driver, was a witness, and detailed the progress to Kenilworth. Before he could start the car he had to flood the carburettor and shut off some of the air. Just before the accident the car was going from twelve to fifteen miles an hour. He sounded the horn when turning the corner. He saw two lights approaching on the wrong side. He put out the clutch and applied the two brakes, but failed to avoid the collision, although the car was almost at a standstill when the impact took place. He was winded by the steering wheel, and considerably dazed. Mr. Parfitt, in addressing the jury, said he felt sure no intelligent jury would return a verdict of manslaughter upon the evidence given that day in support of the contention that Stevens was drunk; but, on the other hand, ten witnesses had conclusively proved there was no truth in the suggestion that Stevens was the worse for drink. The accident was very regrettable, but Stevens was in no way responsible for it. The Coroner, in summing up the case, dealt with the contradictory nature of the evidence as to the alleged drunkenness of Stevens, and said the jury must be able to ear-mark an actual act of negligence on his part before they could bring in a verdict of "Manslaughter." The jury found that Hales met his death by accident.

POLICE TRAPS.

THERE is a measured mile in the village of Minskip, near Boroughbridge.

IN the Huddersfield Police Court a solicitor has been describing a trap in the Leeds Road, Huddersfield. There were, he said, four officers stationed in the road, two at one end and two at the other end of the measured quarter of a mile. Each officer had in his possession a stop watch. These watches, before the motor-car came in sight, were all stopped. As the car passed the first two constables, the two stop watches were set going. When it passed the second two officers, their stop watches were set going. At a given interval the signal was given for the stop watches to be stopped, so that the interval between the stopping of the watches was the time in which the quarter of a mile was covered.

THERE is a police trap on the main London to Coventry road *via* Dunchurch. It commences directly after passing a mile out of Dunchurch towards Coventry, and for the next mile and a half motorists should be careful.

A TELEPHONIC trap between Tring and Berkhamsted police station is in daily operation.

AT the cross roads in the village of Wallop, Hants, the police have a measured furlong.

CARE should be exercised in passing through Maidenhead.

CASE DISMISSED.

AT Hailsham Petty Sessions, Lord Ninian Crichton-Stuart was summoned for driving a motor-car at a dangerous speed at Ersham Road, Hailsham, on July 16th. Mr. Andrew Walsh, of Oxford, appeared for the defence. Edward Pape, of Moor Hall, Ninfield, who was in the motor car at the time, said Lord Ninian Crichton-Stuart was driving. There was an accident at a very sharp corner, up to which they had gone at a fair pace. His lordship then slowed down. They came upon a milk cart driven by a boy in the middle of the road. There was a collision, and the cart was upset. His lordship turned the car and ran into the ditch. Witness went to the boy, who was crying, and gave him 2s. 6d.; he further went to find out the owner (Mr. Lade), apologised, and offered to pay—and had paid—for the damage. The car was going about eight miles an hour when they met the cart. The defendant, in evidence, said that the corner was an "S" curve with a very sharp second turn, which looked as if it were the end of the road. There was a descent, and he naturally slackened speed. He was nearer the left-hand side than the right. He suddenly saw the milk cart, and slewed his car round into the ditch. It ran through it on to the road again, after hitting the cart on the off splashboard. The cart was overturned, but no part of it was against the hedge; in fact, witness passed several times between the cart and the hedge. No complaint was made. He paid the damages and other money to the boy, not because he felt he was legally liable, but "purely in the motoring interest." The magistrates retired to consider their decision, and on their return the Chairman said the majority of the Bench had given the defendant the benefit of the doubt, and the case would be dismissed.

CASES AGAINST MOTORISTS.

Place.	Summoned for	Fine.
Scarborough	Driving recklessly	£5, etc.
Todmorden	No rear light	£1, etc.
Andover	Driving dangerously	£3, etc.
County of London Sessions	Causing bodily harm to a woman by furiously driving a motor-car	Three months' imprisonment.
Middlesbrough	No licence	£8.
Marylebone	Driving dangerously	£10.*
Manchester	Refusing to allow constable to inspect the record of the names and addresses of persons driving cars	£1, etc.
Market Bosworth	No licence	2s. 6d., etc.
Pontypridd	Furious driving	30s., etc.
Liverpool	,, ,,	10s., etc.
Dover	No rear light	Dismissed on payment of costs, 11s.
Marlborough Street, W.	Dangerous driving	£10, etc.
Windsor	Negligent driving	Dismissed.
Huddersfield	Exceeding legal limit	£3, etc.
Bristol	Not making a record of the name and address of a person having a motor-car	5s., etc.
,,	Driving backward for a distance greater than was safe	40s., etc.
Aberystwith	Driving dangerously	21s., etc.
Ross	No number plate	£1, etc.
Knaresborough	Driving dangerously	£5, etc.
Bray	Driving at excessive speed	5s., etc.
Dolgelly	Not stopping when requested	Dismissed.
Mansfield	Driving to public danger	£5, etc.*
Stratton (Devon)	Driving to public danger	£5, etc.
Chelmsford	Neglecting to give information which would lead to the identification of a person driving a motor-car	£5, etc.
Brentford	"Causing to be travelled a light motor-car with improper tyres"	£10, etc.
Maidenhead	Excessive speed	£5.
Clacton	(1) Driving unregistered car; (2) driving without licence	(1) 10s., etc.: (2) 10s.
Berkhamsted	Beyond legal limit	Dismissed on payment costs.
Winchester	Driving dangerously	5s.
Tonbridge Wells	,, ,,	40s., etc.*
Tonbridge	No rear light	5s., etc.
Hailsham	Driving at dangerous speed	Dismissed.
Penge	(1) Reckless driving; (2) not showing licence when requested; (3) not having bell or horn on motor-cycle.	£7 6s.
Glasgow	Colliding with farmer's cart	10s., etc.
Eccles	Furious driving	10s., etc.

THE

Motor-Car Journal.

VOL. VI.] LONDON, SATURDAY, OCTOBER 1, 1904. [No. 291.

Published Weekly by CORDINGLEY & CO., 39 & 40, Shoe Lane, London, E.C.

COMMENTS.

AMONG the most serious evils that can befall a motorist dogs certainly rank high, and, in spite of "cut outs" and other devices, serious accidents daily occur from these canine depredators. As a rule one smash up cures the dog, but, considering the number of dogs, even this method would become monotonous. However, as owners of dangerous dogs are being "listed" in some quarters, and the question being generally discussed in motoring-circles, the following incident is of interest. The daily motor-cycle rides of Mr. A. E. Bradford, of Wolverhampton, carry him through four of the manufacturing towns of the Black Country, and on several occasions he has narrowly averted accidents owing to dogs and fowls. On one hill he was tackled twice by a collie whose owner could not be located. A few days later, at the same spot, the animal made a desperate rush, and, the motorist being unable to pull up, struck the front wheel, the impact being such that the handle bars made a half turn in the socket and Mr. Bradford came with a crash to the ground. A bent pedal, two radiating fins minus, and a cut hand constituted the principal damage. After collecting his watch and other sundries he made a tour of investigation. The owner proved to be Mr. Golcher, of Darlaston. The motorist communicated with the police, who in due course favoured him with an official communication intimating that the dog was to be executed on the following day. If motorists would, on locating owners of dangerous dogs, take their names and warn them, their animals will get salutary lessons in behaviour. At present such owners generally laugh at the dogs' antics; but a warning from the police will place them beyond such false security.

◆ ◆ ◆

An Irish End to End Run.

MR. L. R. OSWALD-SEALY has made a successful attack on the Irish End-to-End Record, covering the distance of 392 miles in 29 hours 58 minutes. Owing to the nature of the roads to be traversed, some of the very worst to be found in the whole country, the Irish end to end trip has had very little inducement for the Irish motorist. It was with no little surprise reported by the motor cyclists that in the month of September of last year Mr. Oswald-Sealy had started on a record ride from Mizen Head to Fair Head, which he accomplished in 32 hours 49 minutes. This record remained undisturbed until August of the present year, when Mr. C. B. Franklin reduced the time by 1 hour 19 minutes, his total time being 31 hours 30 minutes. On Thursday of last week Mr. Oswald-Sealy left Mizen Head on his 3½-h.p. Brown at 8.45 a.m., with the object of regaining the record. Before reaching Gouleen he received his first puncture, and arrived at Skibbereen at 9.55 a.m.; from this to Bandon he had trouble with his exhaust valve tappet, and on calling on Mr. Slattery, at Bandon, had the defective part made right. After a delay of over an hour he got to Cork, and on through Mitchelstown, where he arrived at 4 p.m. to report several punctures. From this to Cahir the roads improved, and at the latter place he took a supply of petrol on board. Nearing Cashel a collision with a dog brought him down; the rider fortunately escaped, but the machine suffered to the extent of a bent crank and pedal pin and the breaking of the exhaust valve lifter. He proceeded on his journey, and, passing through Johnstown, Durragh, Monasterevan, Kildare, arrived in Dublin at five minutes after midnight, having in the meantime covered 243 miles in 15 hours 20 minutes.

◆ ◆ ◆

A Record.

AFTER an interval, during which he had supper, and the crank set and valve repaired, a start was made at 12.55 a.m. When nearing Balbriggan another dog caused trouble, this time more serious, Oswald being completely unseated and deposited on his back in the middle of the road, while the machine was temporarily disabled, the petrol feed pipe being broken and the crank again bent. Fixing the pump connection as a temporary repair, the intrepid rider again starting, got to and through Drogheda, Dundalk, and Newry, where he refilled with petrol and repaired, as far as possible, the damage done by the second dog. Proceeding, he passed through Banbridge, Lurgan Cromlin, and Ballymena, with only two punctures to his credit, leaving Ballymena at 12.45 p.m., Ballycastle at 1.45, and Fair Head at 2.12 p.m., thus covering the distance in 29 hours 32 minutes, beating Franklin's record by 1 hour 58 minutes.

◆ ◆ ◆

Motor 'Buses for London.

MUCH has been heard of late with regard to motor-'buses for London, and on Wednesday Messrs. Thomas Tilling, Ltd., placed a Milnes-Daimler motor-'bus upon the road. This is intended for the route between Rye Lane, Peckham, and Piccadilly Circus. It will carry thirty-four passengers. A similar vehicle is to be placed by the Associated Omnibus Company on the route from Charing Cross to the south side of Westminster Bridge, at ½d. fares. The London General Omnibus Company are putting a steam omnibus on the road between Piccadilly and Hammersmith as soon as the necessary licence has been obtained from the authorities at Scotland Yard. Trial trips were taken on three days last week, when a speed of fifteen miles per hour was obtained on level roads in the Metropolis, and at least ten miles per hour up Pentonville Hill. The mileage per gallon of oil was about three and a-half, and the trials were very satisfactory.

◆ ◆ ◆

Balloons v. Motors.

ON Saturday the Aero Club had a combined meet with the Midland Automobile Club at Birmingham. An ascent was made by Mr. C. F. Pollock and Professor Huntingdon, and two hours and ten minutes later the balloon descended at Ross, seventy miles away, Mr. W. A. Brown on his Renault being the first motorist to appear on the scene. The

Digitized by Google

second balloon, with Mr. F. Butler, Mr. C. S. Rolls and Mr. P. Spencer, descended at Monmouth in a little over two hours and remained uncaptured until the expiration of the time during which the aeronauts were compelled to remain on the spot. Among the motorists who scoured the country round for the balloons were Messrs. F. Mitchell (Mercedes), C. S. Baynton (Wolseley), T. C. Aveling (Thornycroft), C. K. Lloyd (Minerva motor-cycle), J. Wingfield (M.M.C.), G. H. Lanchester (Lanchester), A. J. Millership (Lanchester), S. J. Davis (Wolseley), G. Bird (Clement Talbot), C. W. Dixon (Lanchester), R. R. Brown (Wolseley), J. A. Holder (Mercedes), A. E. Holder (Wolseley), H. C. Holder (De Dietrich), and W. A. Brown (Renault).

◆ ◆ ◆

Justice at Exeter.

MR. E. F. STUDD, J P., who is, we are informed, a member of the Exeter bench of magistrates, is apparently of the class of persons known as anti-motorists. He left the bench the other day to prosecute in a case where a motorist had failed to recognise the signal given by a son of Mr. Studd to stop. We did not know that people who were not lawyers were allowed to appear in such a capacity, and the way in which he spoke to the solicitor in the case was a revelation to frequenters of the court. That, however, by the way. His son was driving a horse which

Philippine Natives Trying a Motor-Car.

[*The Automobile.*

was inclined to bolt on approaching a motor-car. The young fellow flourished his whip—a habit that seems familiar, judging from a letter we have received from an Exeter motorist—intending the motorist to stop. The driver of the car, on the other hand, did not see any signal to stop, and further, he believed that the holding up of the hand was the proper signal. In the end, the magistrates on the bench, Colonel Blake and Messrs. W. T. Bayne and C. J. Webber, imposed a fine of £1 and costs.

◆ ◆

Up with the Hand.

THE hand, and not the whip, is, according to the wording of the Act, the means of signalling to motorists to stop their cars. It can be readily understood that the raising of the whip might easily lead to confusion, and absolutely frustrate its purpose; hence the insistence on the hand being used. But if magistrates are to be allowed to accept evidence of the kind brought forward in the Exeter case to which we have referred, no motorist will be really safe. The point is one of some importance to motorists, and the sooner the magistrates can be brought to understand the provisions of the Act with regard to the matter, the better.

The Race in India.

GREAT interest is being aroused in India by the forthcoming race for the Gaikwar of Baroda's cup, which will be run under the direction of the Motor Union of Western India. The distance between Delhi and Bombay, which is approximately 880 miles, is to be traversed by the competing cars between December 26th and January 2nd inclusive. The timing of the competing vehicles between any two places will be made on a basis of twelve miles per hour as a minimum, and thirty miles per hour as a maximum speed. Entries will be received for all cars up to December 1st, and in addition to the cup, which will be awarded on the score of reliability, there will probably be prizes for:—(a) The car in best condition after the trial, (b) the car best suited for work in India, and (c) absence of noise. Considerable importance should attach to the results in connection with the most suitable vehicle for use in the great Dependency.

◆ ◆ ◆

Welsh Justice.

A CASE has just been heard at Carmarthen which is typical of the way in which motorists are being forced to the conclusion that they are often unjustly treated by magistrates. A driver was summoned for recklessly driving a motor-car to the danger of the public, but amongst the witnesses was Captain Thomas, the deputy chief constable of Swansea, who was on the car on the occasion complained of. He testified to the fact that it did not endanger the public safety; and it might well have been assumed that the magistrates would have regarded such testimony as worthy of credence. But the constable had apparently declared that the public was endangered and a conviction was duly made. This is the sort of thing that persuades motorists to offer no defence when summoned, this being more economical than correcting wrong police evidence.

◆ ◆

A Motor Tour.

DR. J. T. ABBOTT, of Tunbridge Wells, recently made a motor-car tour of 1,015 miles in slightly less than fourteen days. From London he, with a friend, started for Holyhead, and had some adventures on the way. At Bicester they had a poor lunch, for which they paid richly, to say nothing of being mulcted in the sum of sixpence for standing the car in the hotel yard. At Shrewsbury they had inhospitable fare, and for standing the vehicle in the stable yard a charge of two shillings was made. A toll of a shilling enabled them to cross Menai Bridge. At Holyhead they paid a sum of thirty-five shillings for the single fare of their 8-h.p. De Dion across to Dublin. Dr. Abbott had a most pleasant tour through the Emerald Isle, and at the local hotel at Kilcullen, "about as big as a cottage," was informed that in the four days of the Gordon Bennett race meeting last year they made £60 for their beds alone. Food and drink were extra—as we well know; for it was the identical hotel we made our headquarters for a couple of hours before the morning of the race, ere we started off on a wild midnight rush around the course.

◆ ◆ ◆

Experiences of Repairers.

THE medical motorist has something to say as to the calibre of some of the repairers he met in Ireland. Mud having clogged up an adjusting pin in the car, he called on an agent in Dublin, feeling sure he would have a stock of spare parts on hand. "The agent probably knew about everything else under the sun except motor-cars, and more particularly the cars for which he was agent. He assured us he knew all about cars, but could not supply us with what we wanted. This we dragged out of him after a long time. His general slack manner irritated us to such an extent that it ended in my friend telling him that although he knew all about cars, and everything else, he did not know enough to get in out of the rain, and that, moreover, we had as much use for him as we had for a headache. This

Digitized by Google

seemed to annoy him, whereat we were glad. I am sure such agents cannot improve the trade in Ireland. Having left the agent's, we now sought a garage. A slight adjustment in the gears was needed. Here let me refrain from criticising the methods of some repairers. 'Ah sure, sor, don't I know all about it; sure, isn't my mechanic the best in Oireland; sure, didn't he mend the Lord Lieutenant's when no one else could; ah, sure, lave it to me and don't dirty your hands.' This was our greeting at the garage. At least six men had a try; next day it was done, and, though many hours were taken to find out how to do it, I only paid a nominal sum. The next time I will do it myself."

◆ ◆ ◆

Some Practical Details.

During the whole time Dr. Abbott had no mechanical troubles and no punctures. He travelled 1,050 miles in ten running days. His tyres were almost without a scratch. The longest run on two gallons of petrol was seventy-three miles. The total cost of petrol was £2 5s. He is already looking forward to next year, when he hopes to have more time to run over to the Emerald Isle, where police traps are unknown, and where the true sporting element exists.

◆ ◆ ◆

Magistrates and Prejudice.

At the Congleton Court a magistrate whose prejudice against automobiles had been publicly exposed has narrowly escaped sitting in judgment upon a motorist summoned to appear before him. Mr. Bedworth, of Harley, was the defendant, it being alleged that he had driven a car at a speed which was dangerous to the public. The case was adjourned on the first hearing, and on the second occasion Mr. Bedworth laid an objection to the proceedings. On the previous Monday Mr. Barlow (one of the magistrates then sitting) made the following remark before the case was heard, or any evidence taken at all, that "these motors want stopping." To that remark he addressed a letter to the Press giving his view upon Mr. Barlow's remark to the effect that he was pre-judged, and that before he heard any evidence he distinctly and deliberately said that these motors must be stopped. Therefore, whatever he now said, and whatever defence he might bring before them, he was only going to be listened to, apparently, with contempt. The magistrates entered upon a somewhat lengthy discussion, after which Mr. Barlow removed to a seat farther along the Bench, where he could be a quiet listener to the evidence without taking part in the deliberations of the Bench, the magistrates adopting the suggestion that Mr. Barlow should not adjudicate in the case.

◆ ◆ ◆

The City of London Inquiry.

On Tuesday the Local Government Board inquiry into the question of restricting the speed of motor-cars passing through the City of London to ten miles an hour was held at the Guildhall, by Mr. E. P. Burd. Sir Homewood Crawford, the City Solicitor, who conducted the case for the Corporation, gave some interesting figures with regard to the City traffic. The day population of the "square mile" was 359,940 persons, and 1,250,000 people entered it daily, while the number of vehicles was upwards of 100,000. In one day 248,000 persons used the crossing in front of the Mansion House, without counting 61,185 who passed through the subways. It has been ascertained that in the City there are 48½ miles of streets. A police census of traffic, which had given the following figures of the number of vehicles passing one point in a day from 8 a.m. to 8 p.m. was given in evidence as follows:—

	'Buses, etc.	Cabs.	Other Vehicles.	Total.
Mansion House	8,391	8,365	12,989	29,745
Mansion H. Station	3,809	6,819	10,391	21,019
Ludgate Circus	4,742	3,763	17,217	25,722

Captain Nott Bower, the Commissioner of the City Police, acknowledged that he had heard nothing of accidents to life or limb and that motorists had been very careful—but, he added, with almost Dickensonian wisdom, "accidents might happen." No summonses had been issued under Section 1 of the Motor Car Act, and he had no positive evidence of danger to the public. On the other hand the Commissioner had to admit to Mr. Moresby White, who represented the A.C.G.B.I., that a large number of cab-drivers had been summoned for driving furiously. And yet no application for restricting their speed limit has been made, although from tests made by Messrs. Straight and Swindley on the Embankment on Monday it would appear that these vehicles travel at anything from twelve to fourteen miles an hour.

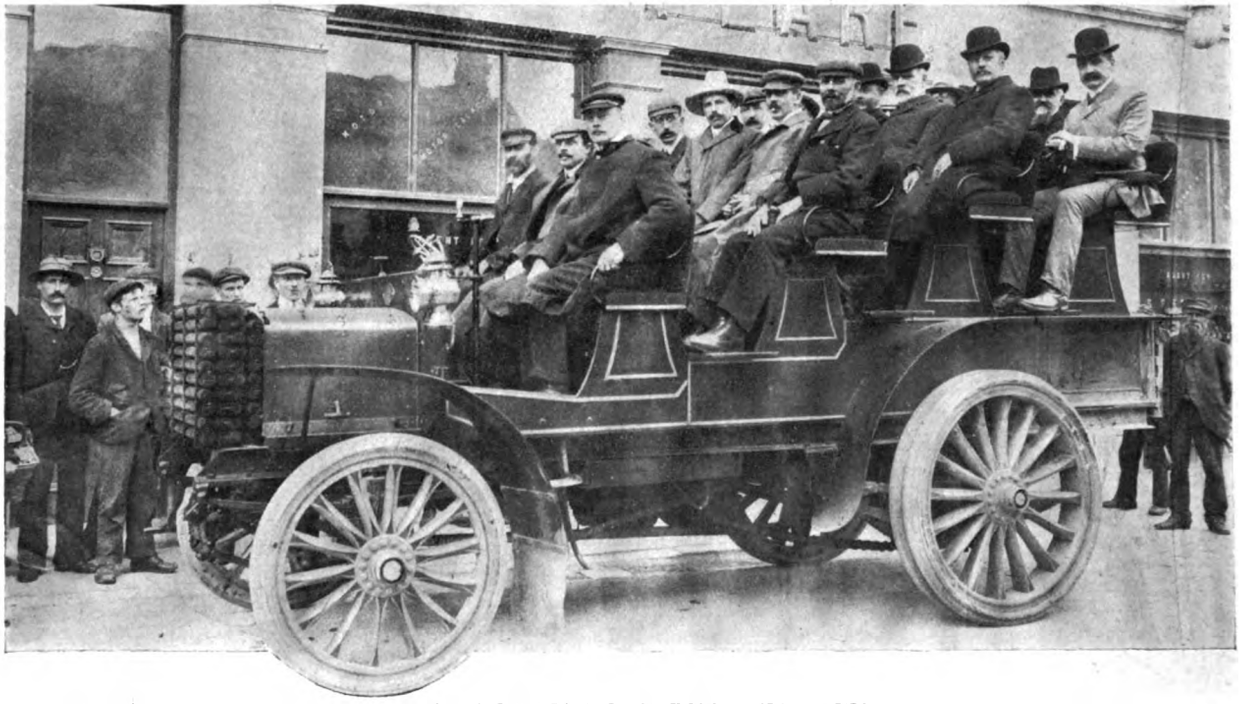
When is a Motor-cycle not a Motor-cycle?

AT the Leeds City Police Court, on Tuesday, before Mr. C. M. Atkinson (the Stipendiary Magistrate), Mr. B. Scarth, of Harrogate, was summoned for driving a motor-bicycle without having an identification plate in front, and also for not producing his driver's licence. The defence was that he was not driving a light locomotive. He was riding a bicycle which had motor attachments, but on the occasion in question he was using it as an ordinary pedal-driven bicycle, and the motor was not in use. The Stipendiary Magistrate said the question was whether the defendant could be said to be driving a motor-car at the time he was asked for his licence. He thought there could be no doubt that if the motor-cycle was in such a condition that it might be stopped at will, without getting off, he would be liable if he did not produce the licence; but the evidence was that it could not be used as a motor-cycle at all without alterations and adjustments being made which would necessitate the driver getting off, and which would occupy some time. In this case it was not being driven as a motor-cycle, although it was a motor-cycle. It was a difficult question. He was prepared, if the defendant liked, to have the matter discussed, but if he was prepared to admit a breach and pay the costs, rather than come to court again without creating any precedent, he would adopt that course. So far as the defendant was concerned, it was a matter of no interest, but to the public it was a matter of interest. Mr. Scarth stated that he would pay the costs, which amounted to 8s.

◆ ◆ ◆



The Motorists' View of the Ten Miles Restriction.

COLONEL HOLDEN, the chairman of the Automobile Club, pointed out at the City of London inquiry that if ten miles were the limit of speed, the spectacle would be presented of a car falling behind other vehicles. He did not know how the police could secure reliable timing results over short distances in the City—a very different place to the rural localities in which police traps have hitherto been set. At ten miles an hour a car would travel 45 ft. in 3 sec., and an error of one-fifth of a second would make a vast difference in the speed shown. As regarded skidding, several devices now in common use would avoid that. Mr. Everard Calthrop stated that a motor-car could be stopped in 50 per cent. less time than a cab; that is to say, that if a cab could be allowed ten miles an hour, a motor-car could be permitted to travel with equal safety at fifteen. Mr. Jeffreys appeared on behalf of the Motor Union and Messrs. J. R. Nisbet, A. Robert, H. A. Cunis and W. H. Wells having given evidence the inquiry closed. It was generally admitted that the City authorities made out a very lame case, and that their application was very badly defended.

◆ ◆ ◆

Non-stop Runs.

THIS is apparently the season of tours and runs. In addition to the Oldsmobiles now on their long pilgrimage, Mr. A. Ford, of Liverpool is on a run of 3,600 miles on a 15-h.p. Darracq, which he hopes to finish without stopping the engine; and on Monday next Mr. D. M. Weigel will start at daybreak to drive over the 600 miles of roads used in the small car trials in Herefordshire on an 8-h.p. Talbot car. The attempt will be made to do the whole distance without stopping, and Mr. Weigel hopes to accomplish his task within thirty-six hours.

The Thornycroft Petrol Public Service Vehicle. (See page 642.)

F. R. and F. T.

TO-DAY (Saturday) two new county boroughs are being constituted, and consequently have to conform to the provisions of Section 2 of the Motor Car Act, 1903, with reference to having an index mark. The Local Government Board have therefore determined that the index marks distinguishing the new county boroughs shall be as follows:—Blackpool F.R.; Tynemouth, F.T.—letters which those who possess copies of the *Journal's* Identification Card may now add to their list. The selection of the letters seems to have been on the same haphazard principle as the original indexing. The single letter F. signifies Essex, F.P. is Rutlandshire, and now the succeeding letters of the alphabet refer to northern towns on the West and East Coast respectively. Was there ever such a lack of system?

MOTORISTS in the Bristol district are being organised for defensive purposes.

A 6-H.P. WOLSELEY car has just been sent out to Trincomalee, India, for Lieut. D. S. Skelton, R.A.M.C.

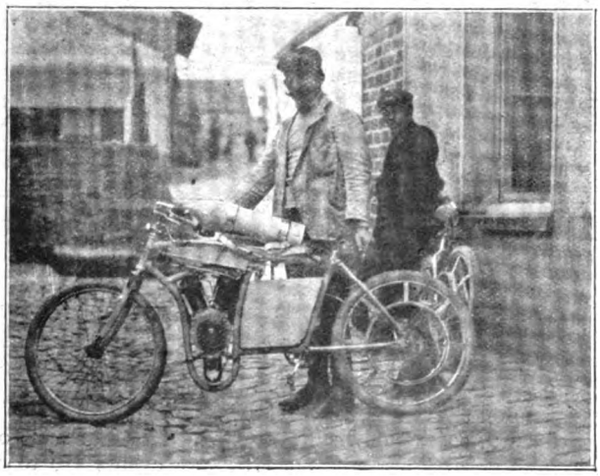
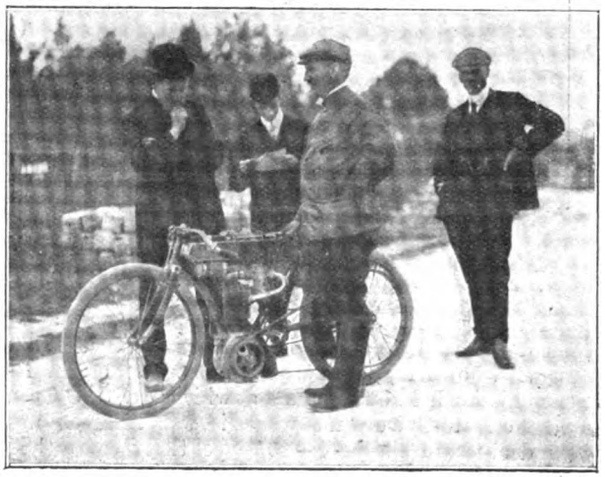
THE INTERNATIONAL MOTOR-BICYCLE RACE



The first race for the International Motor-Cycle Cup, founded by the Moto-Cycle Club de France, was run off on Sunday last on a fifty-four kilometre circuit, about fifty miles from Paris. The starting point was between Saint Arnoult and Dourdan, the route followed being Etampes, Le Foret-le-Roi (neutralisation), Authon, Ablis (neutralisation), St. Arnoult; the circuit having to be covered five times to make the total distance 270 kilometres (about 169 miles). Four countries had sent in challenges to the French Club, but as one country was represented by a single rider, and two others by two each, there were only eleven competitors in the race, these being shown in the order of starting in the appended table:—



Demester, the Winner of the Race.

Silver on his Quadrant.

Tomann and his Laurin-Klement.

Petersen and his Jurgensen.

Rider.	Country.	Machine.	Weight of Machine.	No. of Cylinders.
			lb.	
1. Lamberjack ...	France	Griffon	108·6	2*
2. V. Wondrick ...	Austria	Laurin-Klement	116·1	2*
3. Rignold... ...	England	Lagonda	106·4	1
4. A. Mraz ...	Germany	Progress	116·6	1*
5. N. Petersen ...	Denmark	Jurgensen	—	—
6. Inghibert ...	France	Griffon	109·1	2
7. Tomann... ...	Austria	Laurin-Klement	115·5	2*
8. W. Hodgkinson	England	J.A.P.	109·4	1
9. Tolksdorf ...	Germany	Progress	116·4	1*
10. Demester ...	France	Griffon	109·4	1*
11. T. Silver ...	England.	Quadrant	109·3	1

* Magneto ignition.

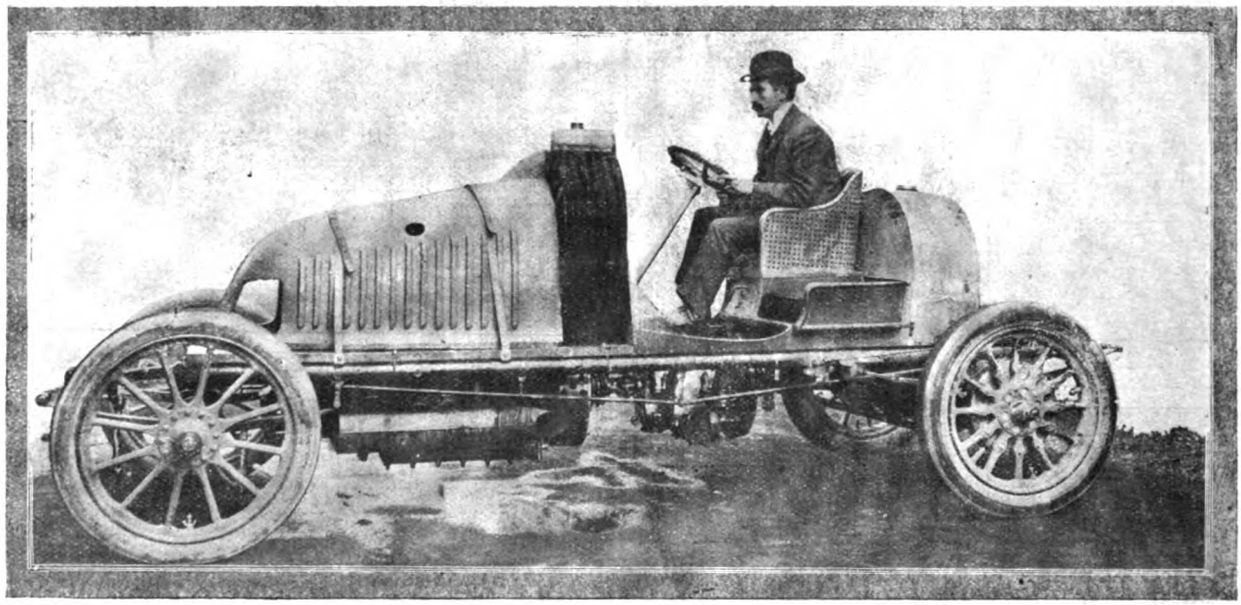
The weighing in of the machines was carried out on Friday and Saturday of last week, 110 lb. being the limit, with an allowance of 6·6 lb. for those machines having magneto ignition. C. Mueller on a Brennabor machine was to have also competed for Germany, but his machine was found to be too heavy, and afterwards was damaged by fire.

The start took place at 6 a.m. in fine weather and in the presence of a large number of interested spectators, having regard to the early hour, the crowd increasing as the morning wore on. The eleven competitors were sent off at two minute intervals by M. Tampier, the timekeeper to the A.C.F., Silver, the last man, getting away at 6.20 a.m. There was a wait of about half an hour, and then the cry, "Here they come" went up, Wondrick, the Austrian, rushing by. He covered the first lap (slightly under 34 miles) in 56 min. 31 sec. gross time, and was closely followed by Petersen and Rignold, while Demester, who passed fourth, was the first Frenchman to appear. Lamberjack, who started first, and was a hot favourite, arrived last, a long way behind. He complained of several punctures caused by nails. Hodgkinson and Silver, of the English team, were also victims of punctures from the same cause, and were not checked at all on the first lap; in all, nine riders completed the first round within the time limit, but before the second circuit was completed the punctures had reduced the field to six. This time Wondrick was still leading, but Demester had run into second place, being only six minutes behind the leader. All hope of an English rider winning the race had gone, Rignold, like the other two members of the team, having had to retire through punctures. When the third circuit was completed it was seen that Demester had taken the lead, and although Wondrick passed second, he was fully 19

Digitized by Google

min. behind. Only five of the eleven starters had survived at that point of the contest, these being the three Frenchmen and the two Austrians. No incidents or accidents were recorded in the fourth and fifth laps, but Demester further increased his lead, and scored a popular win for the home team, while Tomann had the honour of taking second place for Austria; the Frenchman, Inghibert, being third. The official net time of the winner for the 270 kilometres was 3 hrs. 43 min., which works out at an average of about 45 miles an hour. In the French eliminating race over the same course, a few weeks ago, Lamberjack covered the distance in the net time of 3 h. 30 min. 14 sec.

The names and times of the competitors who finished are as follow:—(1) Demester (France), 3 hrs. 43 min. 43 sec.; (2) Tomann (Austria), 4 hrs. 54 sec.; (3) Inghibert (France), 4 hrs. 14 min. 32 sec.; (4) Lamberjack (France), 4 hrs. 44 min. 53 sec.; (5) Wondrick (Austria), 4 hrs. 53 min. 41 sec.



The poor result of the race is undoubtedly due to the fact that every one of the competitors sustained several punctures, owing to the course being strewn with nails. The committee intend to send a complaint to the police authorities, with a view of discovering, if possible, the authors of the mischief.

CONTINENTAL NOTES.

The 60-h.p. Renault Racer.

Two views are given herewith of the 60-h.p. car which Messrs. Renault Freres have built to the order of Mr. W. Gould Brokaw, jun., a prominent American motorist, for competition in the Vanderbilt Cup Race in the United States on the 8th inst. The four-cylinder engine, which is capable of being accelerated up to 90-h.p., is provided with mechanically-actuated inlet valves and the usual high tension ignition. The radiator is quite a new departure; as will be seen, it forms the dashboard, and consists of a series of ribbed radiating tubes arranged in circular form and provided with a fan. The circulation is on the thermo-syphon system, a small water tank being located at the upper part of the coil. The clutch is of the metal to metal type; three speeds forward and a reverse are provided, the drive on the top speed being direct. The front wheels are 810 mm. diameter, shod with 90 mm. tyres, while the rear pair are 820 mm. diameter and have 120 mm tyres. It is stated that the vehicle, which weighs complete about 950 kilogrammes, is capable of attaining a speed of over 90 miles an hour.

The 60-h.p. Renault Car built for Mr. W. Gould Brokaw, jun., for the Vanderbilt Cup Race.

The judges held a meeting after the race with reference to the complaint of the competitors regarding the punctures, and the announcement was made that they had decided to cancel the race. The matter was, however, considered at a meeting of the International Commission held on Monday, at which Mr. M. O'Gorman represented the Auto-Cycle Club, when it was resolved not to approve the decision of the judges to cancel the race, so that the result as given above stands; France thus having the honour of winning the first competition.

THE Enfield Motor Car Co., Redditch, have appointed Mr. W. M Jenkins to the position of works manager. Mr. Jenkins was for a period general manager of Garlick's Motor Co. at Cape Town.

ONLY seven cars have been entered for the motor-vehicle competition which is to be held next week by the French military authorities. The competitors include three Hautiers, two Aries, a Cottereau, and a Latil.

THE new motor chemical fire engine at Leicester, which was only delivered there on Tuesday, was being driven up a road for inspection by a deputation from Glasgow, when it came into collis on with a coal cart. Baillie Clelland, who was standing on the platform of the engine, had his leg broken, and was removed to Leicester Infirmary.

The Transatlantic Motor-Boat Race.

A meeting of the Transatlantic Cup Executive Committee was held last week in Paris, Baron Henri de Rothschild presiding. It was decided that the committee should also have control of the Coup de la Méditerranée, a race across the Mediterranean, from Toulon to Algiers, with resting places, if necessary, at the Balearic Islands on the one side, or Corsica or Sardinia on the other. As the Mediterranean and Atlantic events are to mark a new stage in the motor-boat movement by introducing larger craft, it was decided that no limit should be fixed to the size of the vessels competing for the cups either in regard to length, breadth, or depth. To be qualified every vessel must be equipped with an engine that is theoretically capable of being started in ten seconds. The craft must give a minimum speed of fifteen knots. It was also resolved that in neither the Mediterranean nor in the actual Transatlantic event would any of the competing craft be allowed to take fuel supplies on board between the starting and finishing points. Of the minimum number of six men that each must carry two are to be qualified navigators. In regard to the period of the year at which the Transatlantic Cup could most safely be raced for it was decided that July was the most suitable month. No fewer than thirty owners have already notified their intention to enter craft provided the rules to be drawn up shall appear to them to be suitable.

Falconry and Motoring.

The ancient sport of hawking and falcon flying is being revived in France in a novel form. Highways and by-ways of Normandy are filled with merry troops of motor-cars, whose owners carry hooded falcons on their wrists. From Dieppe and down the valley of the Dun, on the plateau of Veules les Roses, the sport has become immensely popular. Old books are being consulted for hints, and everything done to make the pastime exactly like that of our ancestors. The birds, quite unaffected by the speed of the vehicles or the tooting of the horns, are as ready to return to the owner's leather-clad wrist as though he rode the charger of old instead of a modern automobile.

◆ ◆ ◆

The Dourdan Mile and Kilometre Trials.

Already twenty-seven entries have been received for the speed trials which are to be held by the "Velo" at Dourdan on Monday next, among them being a Napier. Contrary to the original arrangements, it has now been decided to time the standing mile and the flying kilometre separately. It has also been determined not to classify the cars under a general heading, the competing vehicles being of such different horse-powers and cost.

◆ ◆ ◆

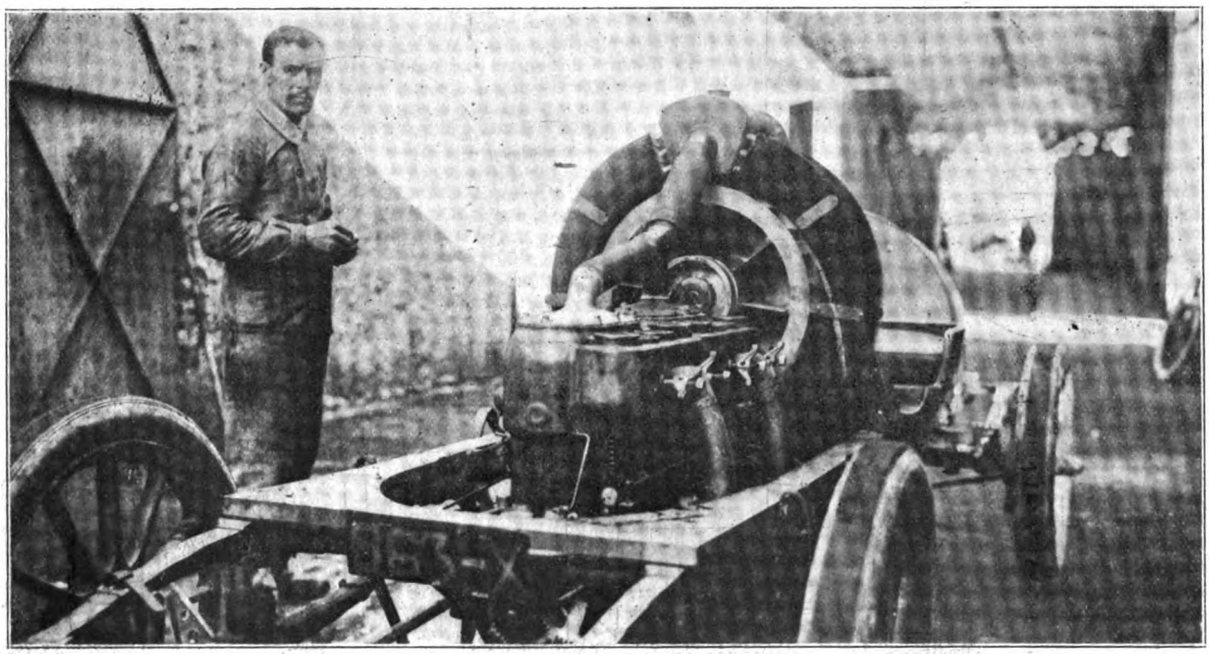
river Garonne and the Canal du Midi, to the Mediterranean. Already fifteen entries have been sent in for the event.

◆ ◆ ◆

Kilometre Speed Trials in Switzerland.

The Swiss Automobile Club held a series of kilometre speed trials with a flying start on the Geneva-Clancy road on Friday last week. The best time of the day was made by M. Dufaux, who, on the vehicle built to represent Switzerland in the 1904 Gordon Bennett race, covered the kilometre in 31 1-5 sec.

◆ ◆ ◆



Motor Vans in Paris.

The French Post and Telegraph authorities in Paris are about to put into service fifteen electrical motor-vans for the transport of mails. Twelve of the vehicles will be constantly at work, the remaining three being kept in reserve in cases of breakdown. The vans, which are designed to carry a load of between 12 and 13 cwt., and weigh complete 1 ton 11¾ cwt., are intended to replace twenty horse-drawn vehicles.

◆ ◆ ◆

Motor-Cycle Racing in Germany.

A motor-cycle race around Berlin was recently run, the distance being a trifle over 149 miles. There were forty starters, of whom thirty-two completed the journey. The best time was made by Herr R. Muller, who covered the distance on a 3-h.p. Brennabor in 6 hrs. 48 min. 53 sec.

View of Engine and Radiator of the 60-h.p. Renault Car built for the Vanderbilt Cup Race.

The Semmering Hill Climb.

The Austrian Automobile Club's hill-climbing competition took place at the Semmering on Sunday last. The Semmering is a mountain which rises to a height of 3,000 feet above the level of the sea, and is situated about two hours' journey from Vienna. On the summit is a fine hotel, the Hotel Erzherzog Johann, opposite the entrance of which is the little obelisk which marks the boundary between the provinces of Austria and Styria. The Semmering seems to have become the classical hill climb for Austria, and the start of the competition takes place at Schottwein, the distance being ten kilometres. The heavy car class was won by Braun on Herr Dreher's 80-h.p. Austrian Mercedes in 8 min. 11 3-5 sec. Duray on an 80-h.p. Darracq was second in 8 min. 32 sec., and W. Poege on Mr. Clarence Gray Dinsmore's 80 h.p. Austrian Mercedes third, in 8 min. 38 3-5 sec. The winner of the light car section proved to be Hieronymous, who with a Spitz car ascended the hill in 8 min. 52 2-5 sec. The best time in the 110 kilog. motor-cycle class was made by Nicodem on a Puch motor-bicycle, time 10 min. 21 3-5 sec.

THE THORNYCROFT PETROL PUBLIC-SERVICE VEHICLE.

MESSRS. JOHN I. THORNYCROFT AND CO., LTD., have recently taken up the construction of public-service vehicles, one of which is illustrated herewith. As will be noticed, the body takes the form of a char-a-banc, the seats increasing in height towards the back, so as to enable all the occupants to obtain a clear view forward. The body is easily removable, so that the car can be converted into an omnibus or other covered vehicle for winter use. The motor is of the four-cylinder vertical type, capable of developing 20-h.p. at its normal speed. The engine, including the governor and the two to one gear, is entirely enclosed, lubrication being on the "splash" principle. The cylinders are cast in pairs, the water jacket being made in one with the cylinder proper. The exhaust ports of each pair of cylinders are connected in the casting and are then brought into a common exhaust-pipe by means of a bridge-piece which has gills cast on its exterior surface in order to assist in cooling the exhaust gases before they enter the silencer at the rear of the car. The gases pass from the exhaust pipe to the silencer through a series of small holes; they are thus made to take a swirling motion, so that by the time they emerge from the silencer they are cold and escape practically without noise. The clutch is of a special type, enabling the load to be taken up slowly, so preventing undue strain on the car. The gear-box provides four forward speeds of, respectively, three, six, nine, twelve miles per hour, and one reverse motion. All the speeds are controlled by one lever, which is placed to the left of the driver. The lever, by means of a side pressure, is made to engage in either of three racks projecting through the side of the gear box. The inner ends of these racks are attached to the sliding spur wheels. The two racks not in mesh with the quadrant are held by an automatic stop plate, which makes it impossible to get more than one gear in mesh at a time. The power is transmitted from the gear box to the back axle by means of a single centrally-located chain. A powerful foot brake is applied to a drum on the gear box countershaft. It is so arranged that no additional pressure is produced on the countershaft bearing when it is applied, there being a purely torsional effect. This is an improvement on the ordinary form of brake, with which there is considerable side-pressure on the bearing of the drum when applied. A hand brake acting on a drum on the back axle is also provided. The springs on this vehicle are particularly long and flexible, the rear ones being attached to the under side of the axle box. The road wheels are shod with solid tyres. The vehicle has accommodation for seventeen passengers, and in addition can carry about 10 cwt. of luggage. One of this type has lately been supplied to the London and South Western Railway Company for service between Lymington and Milford-on-Sea, where it has proved a great boon to the inhabitants of the district which it serves, which has hitherto been without any means of communication with the railway and market town. The particular vehicle illustrated on page 638 has been doing some test runs in various parts of Ireland for the different railway companies, and has made some excellent performances. The photograph was taken in Waterford, when there was a number of important railway officials aboard the vehicle.

Figs. 1 and 2.—Elevation and Plan of Chassis of Thornycroft Petrol Public Service Vehicle.

WHEN the Flintshire County Council wrote asking that copies of the Motor Car Act should be issued in Welsh, the Local Government Board humbly requested the council to tell them the equivalent for motor. A reply is being awaited.

MOTOR CYCLING NEWS.

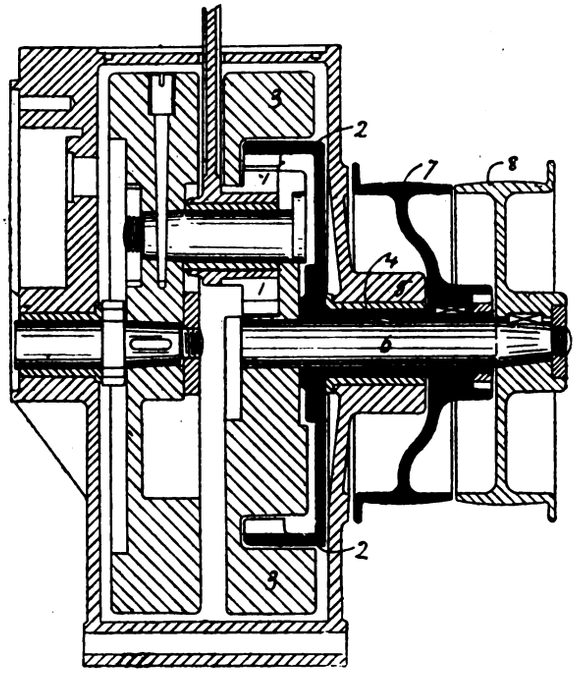
THE Bicester (Oxon) Rural District Council have unanimously passed a resolution of protest to the Oxfordshire County Council against the roads in that district being used for motor-cycle trials.

The "Motor-Car Journal" Challenge Cup, won by C. Collier on "Matchless" Motor-Bicycle.

IT is reported that Demester, the well-known French motor-cycle racer, is contemplating a run from Paris to Vladivostock on his Griffon motor-bicycle.

SEVENTEEN entries have so far been received for the "Criterium du 1-3 de Litre" which the "Auto" will hold at the Parc des Princes track in Paris from the 3rd to the 11th prox.

AT the Linco'n Wheelers' sports at Lincoln last week, in the race for the motor-cycle challenge cup, W. Evans met with a mishap. The winner was W. Pindar on a 2½-h.p. Minerva.



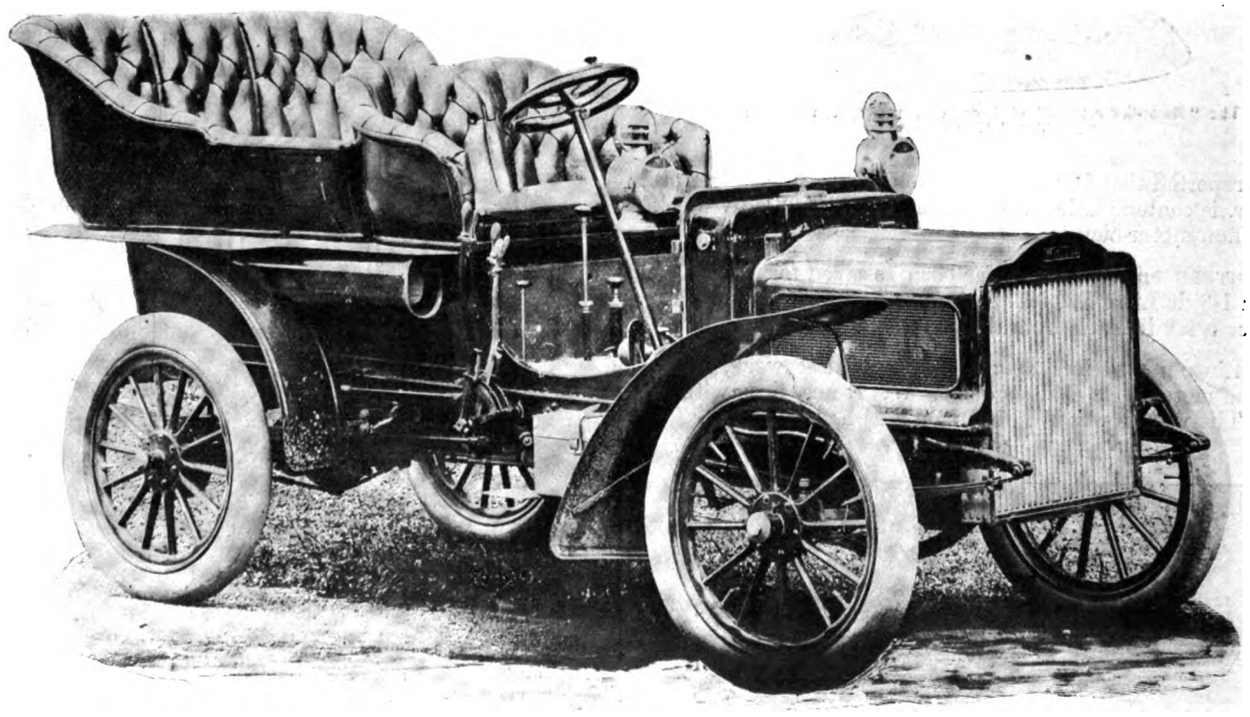
Mr. C. Collier on the "Matchless" Motor-Bicycle, on which he won the "Motor-Car Journal" Cup.

THE Auto-Cycle Club members' fuel consumption trial takes place to-day (Saturday), starting from the Angel, Thames Dittor, at 2 p.m. The route from this point will be to Milford, *via* Guildford and Godalming, and back, about 44 miles. A motor-car will set a fair average speed for the competitors, and any machine which drops behind the car or out of observation will be disqualified. Prizes will be awarded to the three competitors whose machines consume the smallest quantity of spirit.

THE Ulster Section of the Irish Motor Union on Saturday last held a reliability run confined to machines built for two, tri-car, cycle with fore-carriage or trailer, or tandem bicycle or tricycle or quad. The run, a non-stop one for points, was from the junction of the Newtownards and Comber roads at Dundonald, near Belfast, to Portaferry and back, a distance of 56 mile The conditions imposed a stop of half-an-hour at Portaferry, b t during that time no repairs or adjustments were permitted. The maximum speed was fixed in conformity with the legal regulation and the minimum fifteen miles per hour. Five minutes had to deducted for a stop caused by anything other than a punctured tyre, the penalty for the latter being fixed at three minutes, an competitors finishing inside the minimum or outside the maximum time to be disqualified. The following arrived in order printed within one minute of the qualifying time without a stop to their debit :—R. Sinclair (Humber Sinclair), A. W. Hamilton (Ormond R. W. Ireland (Riley) and divide the prizes.

FOR the 1905 season Minerva Motors, Limited, are introducin a 2¾-h.p. motor-bicycle fitted with a two-speed gear, of which

sectional drawing is given herewith. The gear is composed of two gear wheels always in mesh, and is fitted to the interior of the crank case of the motor, the same operation of lubricating the engine thus also oiling the gear. Attached to the big end of the connecting rod in a small pinion (1.) This engages with an internal toothed ring (2), the flywheel (3) being recessed to take the latter. It will therefore be seen that the internal toothed ring and the flywheel are always revolving in the same direction at two different speeds. A hollow shaft (4) fixed to the internal toothed ring is carried to the exterior of the crank case (5) and a solid shaft (6) attached to the flywheel runs through the hollow shaft. Fixed to each shaft is a pulley (7 and 8) to take a flat belt, and to change speed the belt is slipped by a lever from one pulley to the other. The width of the rim pulley attached to the rear wheel of the machine equals the width of the two engine pulleys, so as to ensure the belt always running in line. The control of the two speeds is by means of a Bowden wire operated from the handle-bar.



THE Mars Motor and Cycle Company, Limited, has been registered with a capital of £2,000. The first directors are Messrs. L. Wallet and C. W. Brown.

THE WHITE 15-H.P. STEAM CAR.

WE are this week able to illustrate a new model of steam car which the White Steam Car Company are introducing for the 1905 season. This larger type has been built in response to a demand on the part of the users of the 10 h.p. car for a larger vehicle constructed on the same system. The generator is built on identically the same principle as formerly, simply being enlarged to secure a greater heating surface and more power. In appearance the 15-h.p. car has been changed in several details from the present type, the vehicle, as will be seen from the accompanying illustration, being much more ornate and luxurious. The wheel base has been lengthened from 6 ft. 8 in. to 7 ft. 8 in., giving additional room in the tonneau, and the body is also wider as well as longer, which, together with the fact that the car is higher from the ground, will make it comparatively dustless as far as the occupants are concerned. The front seats are of the bucket type. All the bodies will be built in London.

Other changes of interest in the new vehicle are the adoption of 34 in. artillery wheels with 4 in. tyres instead of the 30 by 3½ in. wheels and tyres, and on the present model a new system of springs has been adopted. The front springs are 40 in. in length and the rear springs 44 in. The latter are not underneath the car but placed a little on each side, and arranged in the manner which has been universally adopted in most of the higher priced European cars. The engine has been enlarged with special reference to the size of the bearings, which will increase its life and power considerably. Additional weight is being placed in the engine construction to enable it to run at a higher speed. The radius of the car has been considerably increased, it being possible to run about 150 miles on one filling of the tanks. The fuel tank of the car is larger, having a capacity in the 15-h.p. vehicle of twelve gallons as against eight gallons in the 10-h.p type. The water tank has not been enlarged, but the condensing arrangements are made so complete by the placing of a fan immediately behind the condenser that the 15-h.p. car can, it is stated, run a very much greater distance on twelve gallons of water than the 10-h.p. car is able to do. The condenser is of an entirely different construction, the tubes running vertically instead of horizontally as hitherto, and being so placed that the necessity for a grease separator is obviated. Several minor points have received attention, the bonnet, for instance, being constructed so as to lift up in front on hinges. The power pump arrangement is so made that rubber hose is done away with, and the throttle is constructed on an entirely different principle. Probably the most important change in the new car is the elimination of any necessity for pumping water by hand. This has been accomplished by providing a hill climbing gear consisting of a pair of sliding gears enclosed in a casing on the rear axle, enabling the car to be run at a 3 to 1 or a 6½ to 1 ratio. The low gear is intended for use on long hills, as it increases the torque of the axle and allows the engine to run at a higher speed, thereby furnishing the generator, through the power pump, with an increased water supply, no matter how long and steep the gradient may be. In connection with this hill-climbing gear there is a neutral point between the gears at which the engine is disconnected from the car. This enables the driver, on starting, to warm up his engine and to increase the steam pressure to the full amount without any hand pumping, as there is always enough water in the generator to make steam for running the engine, but sometimes not enough to move the car. In thus running the engine light the best steaming conditions are obtained without taking the car out of the garage, and the fact that the engine may be disconnected from the car enables it to be easily moved either forwards or backwards, as desired. In the operation of a steam car using a compound engine it has been found that in opening the throttle a sensitive place is encountered at a point where steam is first admitted to the cylinders. It is possible, under certain circumstances, for this sensitiveness to manifest itself in a knocking or rattling sound caused by the back lash in the universal joints. In the new car this has been overcome by providing a light flywheel. From the foregoing description it will be seen that the White Company do not intend to rest on their laurels, and that the 1905 car comprises many new features which will be more appreciated by users of steam cars than petrol motorists. The improvements have been given careful experiment ere being adopted, and while the 1905 car will remain equal in every way to the former models in regard to hill climbing without changing gear, it possesses the added facility of surmounting long, steep grades without requiring the use of the hand pump.

The White 15-h.p. Steam Car.

HERE AND THERE.

MR. J. V. MOINET has succeeded Mr. A. E. Newton as the Hon. Secretary to the Reading Automobile Club.

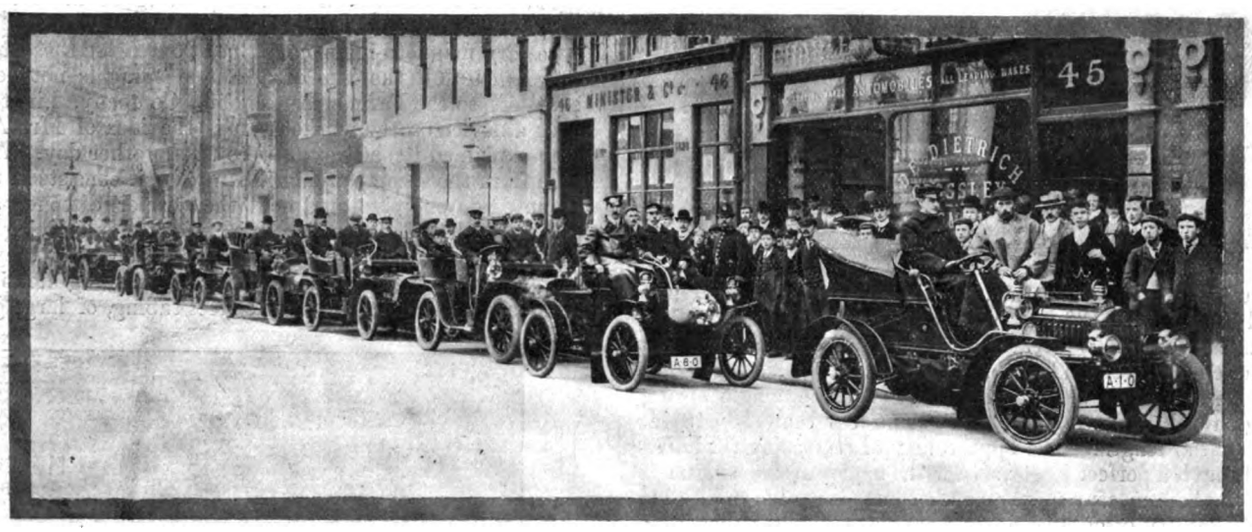
THE Ladies' Automobile Club will visit Mrs. Wilson at Tangley Park, Guildford, on the 15th inst.

MORRISON'S Advertising Agency, of Hull, is now employing a motor-car in the distribution of posters within a distance of twenty-five miles of that town. About three hundred miles are covered weekly.

NEW works for the manufacture of calcium carbide have been established at Askeaton, co. Limerick, by Messrs. Hewson and Company. A mill on the river Deel has been rebuilt, and the water power of the river is utilised to drive a 300-h.p. turbine and generator which have been installed. Raw material is stated to be very plentiful in the neighbourhood, and is found at an average depth of 6 in. from the surface.

DURING the first four days of the tour of the two Oldsmobiles, to which we referred last week, 399 miles were covered, which works out to within a mile of 100 miles a day. On Saturday Mr. W. M. Letts went out to meet the cars, and saw the 7-h.p. car go up Pollhill all the way on the top speed. He was on his Crossley car, and led them back into London by way of the Crystal Palace. The roads were in a terrible state, all grease, but still they both came through in splendid style, and arrived at the garage about seven o'clock. The drivers seemed very pleased at the idea of the Sunday rest. In the different towns through which the cars passed there has been much enthusiasm displayed by the people and everything has gone off beautifully, with the exception of a few stops for tightening a mudguard, adjustment of a lubricator, or little things of that description, but apart from this there has been no trouble. The firm responsible for the enterprise is receiving a number of letters of congratulation on the way the cars are going from people who have seen them. Again, they have had a wire from the Surveyor of Norfolk asking which day the cars run over his roads. On Monday Mr. Letts went over the cars before they started for Norwich, and they certainly seemed very little the worse for the 400 miles. They have now ventured on the most difficult part of the route, *i.e.*, the journey north. If all goes well it will be the third week in October before they again touch London. Last week we gave the itinerary for the present week, terminating at Glasgow to-day (Saturday). On Monday next they will return southward *via* Annan to Carlisle, and the destination each day of the week will be:—Tuesday, Manchester; Wednesday, Shrewsbury; Thursday, Cheltenham; Friday, Newcastle-under-Lyme; Saturday, Holyhead. The next four days will be spent in Ireland.

A GARAGE is being established at Woodhall Spa by Messrs. Humpherson and Company.



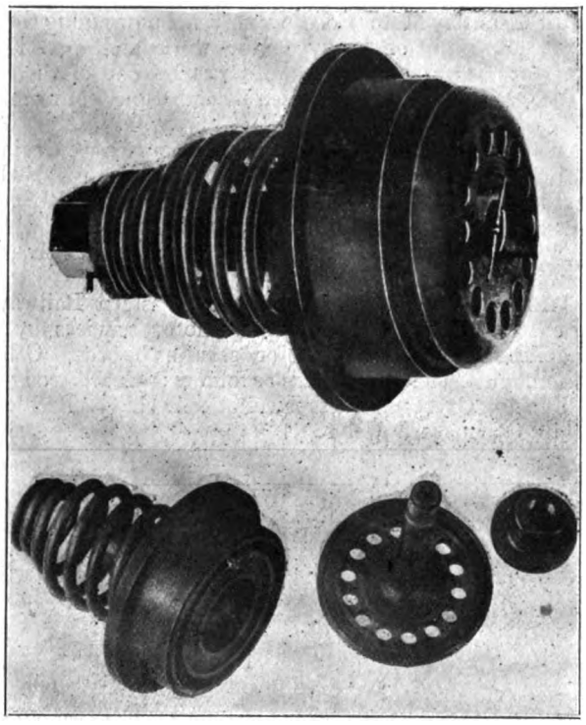
A STEAM 'BUS is to be put on the road between Pulborough and Horsham by the Sussex Motor Road Car Company.

ADMISSION to the Yorkshire Club's speed trials at Wentworth, Woodhouse, will be by way of Flood Hill Lodge, situated at the seventh milestone from Barnsley on the Barnsley-Sheffield road.

THE Maudsley Motor Co., Coventry, are now laying themselves out for all kinds of heavy motor work and petrol launch motors. We have had a 40 miles run on one of their 25-h.p. Lonsdale wagonettes, characterised by smoothness of running and quietness.

A STEAM car belonging to the Western Road Carrying Company, when descending Wicker Hill, in Wiltshire, skidded on the watered road, and, coming into collision with the kerb, turned almost completely round, and was brought to a standstill a few feet away. The granolithic paving was broken, but the damage done was not serious.

THE new time tables of the Great Western Railway Company contain notices of several new motor services by rail or road. Among them is a motor service between Calne and Marlborough. The stations are as follows:—Marlborough, Manton, Fyfield, Overton, West Kennett, Avebury, Beckhampton, Cherhill, Quemerford, Calne.



The Scene at the Start of the Two Oldsmobiles on their Thirty Days' Trial.

MESSRS PETO AND RADFORD, LIMITED, have acquired larger premises for their works at Ashtead, where they will be in a position not only to turn out accumulators, but also accommodate motorists who may be in the district with anything necessary for electric ignition. Charging, repairs, and all accumulator work will be undertaken at their new Ashtead premises, which are situated close to the main road between Epsom and Leatherhead. There is a private road leading off the main road direct into the works, with accommodation for any number of cars, ample power being available for charging electric vehicles of any size.

THE "Otto-Bennett" Company have recently effected several improvements in their "Otto" detachable band. The former solid steel attachment is replaced by flexible wires which can be made taut by an ingenious little lever, which works under the cover. This lever, which is fitted with three notches, enables the wires to be expanded or contracted as desired, rendering attachment and detachment a simple matter. The See bands have also undergone improvement; whereas in the former type the band was not wholly vulcanised, it is now fully vulcanised down to the beaded edge, fitting directly into the rim. Creeping is thus entirely obviated, as is also the possibility of the band working loose.

Digitized by Google

MESSRS. S. F. EDGE, LIMITED, send us some interesting information with regard to the design of inlet valves for petrol motors. They state that for the purpose of comparison "we have taken a valve with a diameter of 3¾ in. seating. An ordinary type of single port valve of this size gives a circumferential length of 10·995 in. If, however, we use the three port Napier valve

in the same diameter of seating, we at once obtain a circumferential length of 13·136 in. When, however, we come to a four port valve, we find a greater improvement still, as we get 17·276 in. circumferential length. In the case of the Napier patent annular valve it has been found that with the single spring and single mushroom we are able to get no less than 18·848 in. circumferential length. The opportunity of increasing the horse-power through a perfect inlet valve with a given size engine is obvious on these measurements, as the same size valve will give an equal quantity of gas in a given time as a plain valve with either less lift or with a smaller valve." Referring to the accompanying illustration, the upper picture shows a complete Napier annular valve referred to, while the lower one shows it in pieces, with its three rings or seatings, making it clear how the gas has access through a greater circumferential opening than the ordinary valve can give for a given size of valve seating.

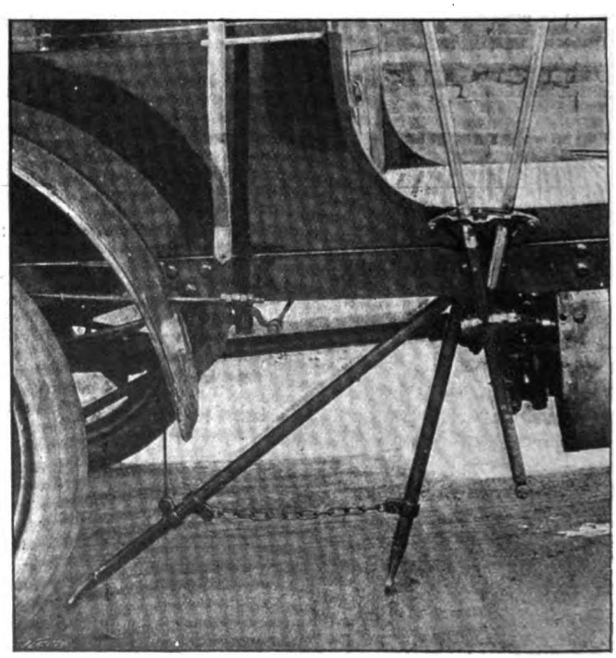
AUTOMOBILES figured very prominently in the American Army manœuvres just held at Manassas, Virginia. In addition to a number of private cars there were three automobiles in camp owned by the U.S.A. Government. One of these was with the artillery battalion of the second division, and is designed to take the place of both the forge and the artillery wagons, both of which are at present included in the equipment of each battery of field artillery. The other two cars were used by the signal corps to assist in the laying of wires about the camp.

In so far as manufacturers strive to assist their patrons in the care of their cars and in the forestalling and rectification of the particular derangements which, in the nature of things, are to be expected, in just so far will satisfaction result. The cars of 1904 are of sufficiently good quality to allow of their few remaining shortcomings being explained in a sincere spirit, without any loss of reputation to any one concerned. Motor vehicles will require care and adjustment and be subject to occasional derangements until the end of time, and it is a pleasure, remarks the "Horseless Age," to see this fact tacitly admitted by manufacturers at large by their treatment of these subjects fully and concisely in their manuals.

NAPIER MINOR won the challenge cup and first prize at the Portmouth Regatta on Saturday week.

MESSRS. REYNOLDS BROS., Peel St., Barnsley, are recommended by a reader as a competent firm for repair work.

SANCTION has been given the Southend Corporation to obtain a loan of £700 for the purchase of a combined motor tip wagon and watering van.



SIGNPOSTS, warning motorists of dangerous corners, in accordance with the Motor Car Act, are to be put up at Bray's Corner, Curtler's Corner, the corner of Fore Street and North Road, and the approaches to the railway station at Saltash.

THE Hozier Engineering Company, Limited, have just completed arrangements to set aside a large portion of their works for delivery vans and lorries, and we understand Mr. J. D. Brimlow, who has a thorough knowledge of this business, has been appointed manager.

AN autumn tour is being organised by the Automobile Club of America. It is to commence on the 10th October, and continue for five days. The route will be from New York to Delaware Water Gap, Philadelphia, Atlantic City, Lakewood and back to New York, a total distance of about 374 miles.

FOR the 1905 season Minerva Motors, Limited, are introducing a new 2-h.p. motor-bicycle at a popular price. Large price concessions have been made in the 2¾-h.p. and 3½-h.p. complete motor-bicycles, to the former of which a patent two-speed gear can now be fitted if required. Prominent among the innovations will be found a special spring fork, while where necessary magneto ignition can be adopted for these models.

ALTHOUGH the idea of a double sprag is not new, it has been left to the Farman Automobile Company, Limited, to put such a device on the market. It is the idea of Mr. A. Pereno, who explained its advantages to us the other day. As will be seen from the accompanying illustration, it consists of two sprags mounted on one pivot and held the proper distance apart by a chain. Each sprag is provided with a forked end, giving altogether four contacts with the ground, so shaped that they will dig instantly into the road and giving astonishing holding power They are constructed of bicycle steel tubing, of large gauge; the

The Pereno Double Sprag.

ends being, of course, solid, and brazed on. Another improvement in connection with the double sprag is that it is arranged to be operated from the dashboard by a lever working vertically. A second form of the sprag has been patented for use on commercial motor vehicles, this having two front rods and two rear rods, giving eight points of contact with the road.

CORRESPONDENCE.

BOWDEN WIRES.

To the Editor of *The Motor-Car Journal.*

Sir,—The unfavourable comment of the judges in the recent light car trials on Bowden wires, and Mr. James R. Nisbet's reply thereto in last issue of the *Journal*, is of peculiar interest to me, and whilst some motorists have been—or profess to have been—fortunate with the system, to me it has been a dismal failure. In justice to Messrs. Bowden one cannot deny that the system is very ingenious, and adds to the smart appearance of motor-cycles and tri-cars, but I have now arrived at that stage when nothing appeals to me unless there is not usefulness in it. I have done everything I could do to make the Bowden wires as fitted to my motor-cycle and tri car a success, but without result. I may have been particularly unfortunate, but they have never been the slightest use to me, and had they acted as they should have done, I shou'd have been spared the indignity and pain of doing a double somersault over the handle-bars and wrecking my machine last November against a sign post on Barnet Common. When my tri-car was delivered at Christmas I again had the Bowden system fitted in the form of band brakes on the two front wheels, which was strongly recommended by the maker. The upkeep of these was no trifle, and I regret to say they were never satisfactory.

In June I was driving my machine by road to Homburg, to witness the Gordon Bennett race, and, being anxious before starting of having my brakes perfectly adjusted by the makers, I wrote Messrs. Bowden, complaining that, as my brakes had never been satisfactory, would they send a man down specially to see what could be done with them, and offering payment for same. They wrote me a courteous letter, saying they were *too* busy to do this, and that, though they supplied the goods to manufacturers, they in no way held themselves responsible for the manner in which they were fitted. I wrote them again, when they replied that a man would call next day, but he never did, and I have never heard from them since, as far as I can remember. Now I was going on a foreign tour, and it was of all importance to me that I should have some safeguard against possible danger, and I do think Messrs. Bowden were wrong in not complying with my request, seeing that I offered to pay them.

I cannot see why Mr. Nisbet should object to the wording of the judges' report on their system, or why the judges should qualify their statement, which is made, after all, in the public interest. The system was criticised in just the same impartial way that any other defect of construction would be, and they have no concern as to who "fitted them." Mr. Nisbet's slur on the "lamentable lack of knowledge in engineering circles" does not justify him or the system he controls in the slightest.—Yours truly,

Owen Joseph.

To the Editor of *The Motor-Car Journal.*

Sir,—I was much surprised at the condemnation of these by the Judges in the small car trials. I have during the past twelve months or more added several refinements to my car and found myself in possession of a clumsy mass of quadrant plates, rods, and bell crank levers with double eyes and spindles.

The whole arrangement was very inconvenient, and continually in the way when I wanted to get at anything.

I have "scrapped" the whole lot and substituted Bowden levers, which I find most satisfactory.

The wires very seldom require removal, as they can be pushed on one side if so required; it can be effected in a few seconds, and fine adjustment is readily made by the stops.

One precaution is needed, the inner wire should be oiled before being passed into the outer casing.—Yours truly,

J. I.

THE SMALL CAR TRIALS.

To the Editor of *The Motor-Car Journal.*

Sir,—Many of our customers have called our attention to the table in the Judges' report, which shows the petrol consumption of the new 7½-h.p. double-cylinder Humberette to be 16·9 miles to the gallon. This is very misleading. The very heavy apparent consumption was brought about by a leakage on one of the runs, caused by the petrol pipe union coming loose from the tank, whereby at least six gallons of petrol were lost on this run. Moreover, each car was debited with every tin of petrol obtained from the stores, whether used or not, and this would account for at least another five or six gallons. Since the trials a test has been made on the car which competed, and we find that it will accomplish well over fifty miles on a two-gallon tin of Pratt's A petrol.—Yours truly,

Humber, Limited.

RECKLESS DRIVING.

To the Editor of *The Motor-Car Journal.*

Sir,—In your issue of the 24th ult. you rightly draw attention to the increasing animus against motor-cars, which is now spreading all over the country, and which, if not checked, will undoubtedly result in such drastic regulations being passed against all motor drivers that the industry will be either severely checked or entirely swamped. The reason for this outcry is easy to understand by anyone who uses the road to any extent outside the suburban districts. They have only to take one walk, ride, or cycle journey, to experience the discomforts of travelling for miles on roads in which even the light of heaven is obscured by the intolerable clouds of dust raised by the passage of monster cars driven by well-dressed Hooligans accompanied by their female partners. These individuals seem to take the keenest delight in driving to the annoyance of every other user of the road; they know perfectly well that they are simply blinding and choking thousands of other users of H.M. highways, just for the sake of being able to brag to their friends about the pace at which they have covered a certain distance, although, as their time is absolutely valueless either to themselves or anyone else on earth, there is no particular reason why they should be so anxious to save it.

To appeal to their sense of the wrongs they are inflicting on other more reasonable users of the highways is simply useless, nothing but punishment of a severe nature will do them any good, and the only course open to the sport at large is to combine and prosecute these vermin with the utmost severity possible. Personally, I intend to begin on my own, and have ordered three speed indicators, which I am going to affix to three motor-cycles, and as I believe every member of our local police rides a cycle, I shall have no trouble in getting a couple of companions for Saturday and Sunday runs, and if we do not have some sport I shall be astonished, and I trust to be able to run to earth two or three well-known scorchers whom I have already got my eye on.

Dog eating dog is not a pleasant spectacle, but in self-preservation something has got to be done, or we shall be back to regulations worse than the old twelve mile an hour limit.—Yours truly,

B. Y. 193.

TYRES.

To the Editor of *The Motor-Car Journal.*

Sir,—In reply to "John Ansonia's" letter *re* tyres, it seems almost incredible that he should have worn out his Clincher-Michelin tyres in 600 miles' running. I should suggest that his clutch must be pretty severe, deserving a frequent dose of castor oil, as I have driven a 16-h.p. De Dietrich with a heavy body, weighing in all 24 cwt., for nearly 4,000 miles without even a puncture. Certainly the hind tyres are protected with Samson bands, but the front ones show very few cuts, speaking well, I think, for the quality of the rubber used in the manufacture of Clincher-Michelin tyres.

I may say that I am in no way interested in the firm, but think "John Ansonia" should look for the cause and put that right, then it should not be "a matter of luck" unless the roads over which he is accustomed to travel are particularly bad.—Yours truly,

H. A. Taylor.

To the Editor of *The Motor-Car Journal.*

Sir,—In reply to "John Ansonia," I also purchased an 8-h.p. Darracq this summer. I have run it about 1,200 miles and the car has not required any repair or a nut tightened. The tyres are Michelin 750 by 85. They do not show any wear, only a number of very fine cuts like marks of the fingernail.

I think "J. A." must have been travelling on top speed all the time with the accelerator pressed down, causing the wheels to slip on the roads, so grinding away the tyres, and he has made a mistake in the distance covered. I only go out about three hours twice a week, as a rule, but I have run over 1,200 miles in four months.—Yours truly,

T. A. Rogers.

To the Editor of *The Motor-Car Journal.*

Sir,—I can sympathise with "John Ansonia" in his tyre troubles. I have driven Darracq cars for the past two years and found they nearly all had the same fault—a great tendency for the clutch to become fierce. On starting, this caused the back wheels to spin round, greatly to the detriment of the tyres. If "John Ansonia" will squirt a little paraffin oil on the clutch before starting on a run he will do away with this trouble and prolong the life of his tyres. The clutch will probably slip to a certain extent for the first mile or two, but after that will be all right.—Yours truly,

M. 470.

To the Editor of *The Motor-Car Journal.*

Sir,—In answer to "Player's" query *re* See fluid, in the *Journal* of the 3rd inst., I have used the fluid for emergency tyre repairs, and find it more or less satisfactory for wayside use, but would recommend "Player" to have his punctures thoroughly vulcanised by a good rubber company. The puncture thus treated renders the tube as good as a new one. I am not quite sure whether the See fluid has a bad effect upon rubber or not. At any rate, I am not altogether satisfied with it.—Yours truly,

H. Hughes.

To the Editor of *The Motor-Car Journal.*

Sir,—Noticing "John Ansonia's" letter in last issue of the *Journal* remarks *re* tyres on a Darracq car, I see he mentions the back tyres only, so I should be inclined to think that, as he is evidently an amateur, he has

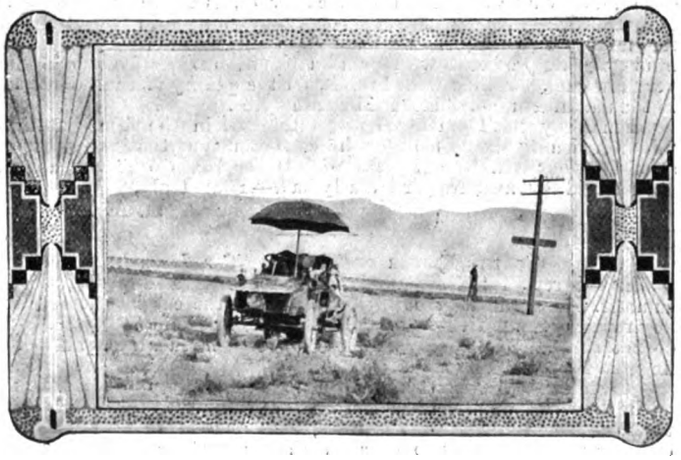
Digitized by Google

been using the clutch roughly. In a new Darracq the clutch is always very fierce, and unless treated very gently will cut the tyres to ribbons. I should advise him to put plenty of good castor oil on the leather, and in starting, changing speed, etc., let the clutch in very gently. I have known a new 24-h.p. Darracq want new back covers once a month till the clutch was seen to, and the driver got used to being gentle with it. I don't think any roads in England would have the effect he described. Hoping this will be of some use to users of Darracqs, and wishing "J. Ansonia" better luck in the future.—Yours truly,

CHAUFFEUR.

WANTED, A CAR.

To the Editor of *The Motor-Car Journal*.



SIR,—Can anyone tell me if there is a car made embodying the following points, as I want a reliable car to go fifteen to twenty miles an hour, that does not require an expenditure of £50 to £100 a year in renewing tyres, covers, gears, chains, etc., the petrol bill being a negligible quantity? Possibly some motor car makers may have more sense than to sacrifice everything to racing, and to think of the requirements of the ordinary man:—1, no gear box; 2, no pneumatic tyres, but something better than solids; 3, no ball or roller bearings; 4, no driving chain; 5, no live axle; 6, no noise; 7, no smell.—Yours truly,

T. T.

A TREMBLER QUERY.

To the Editor of *The Motor-Car Journal*.

SIR,—I am the owner of an 8-h.p. De Dion car, and when on the road it frequently drags, as if something was holding it back, and then it will plunge forward, and continues to drag and plunge for a short distance, till it goes off splendidly for about a quarter of a mile or so, and then starts dragging and plunging again, and so on. The spark is not very reliable, and I think it causes the trouble by misfiring, and then picking up, and misfiring again. I have been recommended to get a trembler coil fitted, as I am told the trouble will then cease. I had the

Alone in an American Desert.

accumulator charged a few days ago, and it is correct, but the trouble arises at the sparking plug. Would any of your readers kindly give me their opinion on the matter, and if they think that by fitting a trembler coil and commutator the trouble will cease?—Yours truly,

PETROL.

OVERHEATING TROUBLES.

To the Editor of *The Motor-Car Journal*.

SIR,—I have a small double-cylinder car with which I have two slight troubles. The first is the water circulation, which, after running well perhaps for days, will stop, and the engine overheat. I then have to wait ten minutes or so on the road to cool down, when, without anything having been touched, the pump starts work and I have no more trouble for perhaps two or three spins. The pump is gear-driven, and is composed of two cog-wheels in mesh.

My second trouble is caused by occasional alarming explosions in the exhaust box, when I switch engine on and off at corners, &c. I should feel obliged if any of your readers could suggest a remedy for both or either of these troubles.—Yours truly,

ENQUIRER.

THROTTLE VALVES AND EXTRA AIR INLETS.

To the Editor of *The Motor-Car Journal*.

SIR,—I should be much obliged if you, or any reader of the *Journal*, could give me information on the following points:—What is the advantage of having the throttle close up to the inlet valves on an engine with automatic inlet valves, as I notice that makers (the Humber) are now fitting them there? Will a butterfly throttle act as well in that position as any other? In fitting an extra air inlet valve to an engine governed by throttle next to the inlets, where should it be fixed on the induction pipe, next to the throttle or to the carburettor?

If the throttle is next to the carburettor, in which position should the extra air inlet valve be fixed then? How often should the springs or automatic inlet valves need stretching out, as I find that on a 12-h.p. car it improves it to give them a pull out now and again.—Yours truly,

S. S. BOUDLEN.

[The idea of fitting the throttle valve close to the inlet valve is simply a matter of convenience, or the most suitable position in the construction. A butterfly valve would work equally well close to the valve as in any other position, but in any case it is necessary for the valve to be well fitted. In the fitting of an extra air valve it is necessary to place this between the throttle and the inlet valve, to prevent the engine from causing a vacuum in the inlet pipe].

OVER-LUBRICATION.

To the Editor of *The Motor-Car Journal*.

SIR,—I should be glad if you or any reader of the *Journal* can assist me in discovering the trouble with my 3½-h.p. De Dion car. It began to smoke very thick, and now it has stopped altogether. The sparking plug and contact seem all right, and the petrol goes through the carburettor.—Yours truly,

H. S.

[The trouble of H. S. is evidently one of over-lubricating, and we would advise a thorough wash out of the engine with paraffin, and a proper charge of lubricating oil. If this is not the cause, it may be that too rich a mixture is being used, which can be remedied by opening the airway of the carburettor.]

A DE DION ENGINE QUERY.

To the Editor of *The Motor-Car Journal*.

SIR,—I have been running a 6-h.p. voiturette (De Dion engine) for about eight weeks, and a noise developed about six weeks since of a clicking, rattling nature, which at a distance has a slight ringing sound. This only occurs when on top speed and immediately upon altering from second to top speed. The sound emanates apparently near or at the contact breaker. It does not affect the run of car in the least as to speed; but, fearing that some part may be taking harm, I should like your opinion, or that of one or more of the numerous readers of the *Journal*, as to probable cause.

I may say that the centre shaft has been examined by the engineer who looks to my repairs, and he says the cause is not there, and appears to treat the matter lightly.

It detracts, however, considerably from my pleasure in driving, and, if possible, I wish to remedy it.—Yours truly,

TRENTHAM.

DARRACQ TROUBLES.

To the Editor of *The Motor-Car Journal*.

SIR,—I have a 12-h.p. Darracq which goes very well when running at a regular pace, but if one has to suddenly throttle down, and especially when running down hill, it misfires badly, which is very startling to horses that may be passing at the time.

If you or any readers of the *Journal* can help me by suggesting a remedy I shall be very much obliged.—Yours truly,

IGNITION.

STEAM CARS.

To the Editor of *The Motor-Car Journal*.

SIR,—I am pleased to see a stand made against the abuse levelled at the Locomobile. It does not deserve abuse; it is a most useful and reliable little car, and, used with common sense, gives no trouble. I have used one for more than three years and am as pleased with it now as when I bought it. My petrol car, by one of the best makers, costs ten times more for repairs and renewals than any steam car.

I do not think "Mechanical Engineer" has ever used a Locomobile. The boilers are not given to leaking; the shell and tubes being of copper, the expansion is equal. It is a most powerful little boiler, with about forty-five square feet of heating surface, and will supply steam enough to average eighteen to twenty miles an hour; the car will climb any hill and will carry a couple of people fifteen to eighteen miles for 1s. The water supply will last forty miles. As to paraffin burners, the makers do not fit these, neither do they recommend them.—Yours truly,

A. H. 59.

To the Editor of *The Motor-Car Journal*.

SIR,—I notice in the *Journal* of the 24th ult. a letter from "Doubtful" asking for the experience of users of steam cars. I am the owner of a Miesse car which I bought second-hand last January, and took over with no instruction, beyond watching a man drive me some 50 miles and going over the engine with the manager of the works where the cars are built. The troubles I have had—mainly due to my own ignorance—are singularly few; practically I have only been stopped on the road for more than fifteen minutes once, when I broke a chain (which was much worn and in bad condition when bought), and recently, when I had some trouble

Digitized by Google

with the burner due to using bad paraffin. The actual engine has given absolutely no trouble whatever, and the burner when fairly treated will give none. The water pump has been repacked once, the air pump has never been touched.

There appears to be no special part liable to break down like the electrical part of petrol cars, and the only part that requires looking after is the nozzle of the burner, which should be cleaned daily (a ten minutes' job). Mine is the old pattern 6-h.p. car, and it will carry four passengers up any hill in the neighbourhood. Of the quietness and small cost of running of the Miesse car I need not speak, for of course paraffin can be obtained at half the cost of petrol. If I were to buy a new car to-day, I should purchase one of the same type without hesitation, and that is the best testimony I can give.—Yours truly,

E. H. O. SANKEY.

HORSE-POWER OF MOTOR.

TO THE EDITOR OF *The Motor-Car Journal*.

SIR,—I have recently purchased a new car, the engine of which has three cylinders 3¾ inch bore and 4 inch stroke and runs about 800 revolutions per minute. It is a very bad hill-climber; on coming to a slight rise it loses its power immediately. It is called by the makers a 10-12-h-p. What horse-power, in your opinion, should this size of cylinders develop, and could you suggest any way by which I could increase the number of revolutions, so as to increase the power?—Yours truly,

N. D.

[An engine with three cylinders 3¾ inch bore by 4 inch stroke should develop fully 12-h.p. running at a speed of 800 revolutions. If the engine does not develop this power there is something wrong either with the construction or with the working. Without knowing the make of the engine it is difficult to give definite information, but we should feel inclined in the first place to see that the compression is good, and if found so we should increase the speed—this by making the contact breaker to still further advance, also by strengthening the springs on the governors.]

SOME MOTOR TROUBLES.

TO THE EDITOR OF *The Motor-Car Journal*.

SIR,—Nowadays, when a really serviceable and reliable motor-vehicle is procurable, most failures can be put down to the inexperience of the owners. That a large number of people drive cars who know practically nothing about their working is very evident. The owner tinkers unsuccessfully for hours and hours and then sends for a competent man to rectify the trouble, which he does in a few moments. The owner with only a smattering of knowledge is sometimes worse off than those who know nothing at all. We all know this man well; a nut drops out from the bottom of the base chamber and he discovers the fact, and thinks his compression gone. It is quite true that De Dion tremblers are rather difficult to adjust, but it is a much better plan to see that the cells are fully charged, first, than to screw and unscrew the platinum-tipped screw for an indefinite period of time, and then to discover the cells are low. Yet this is quite a common occurrence. Then, perhaps, we know the other man with a smattering of knowledge, who in an evil hour takes his engine down when there is nothing wrong with it, and puts it together and finds it absolutely refuses to start. Result, expert arrives and explains that all four-cycle engines usually work better with the exhaust valve correctly set, and not by chance! High-tension wires, too, have their correct places, and if not in their correct places the engine will exhibit rooted objections to starting, much to the alarm of the "man with the smattering," who in the end will seek the inevitable expert. This list could doubtless be prolonged, but it is sufficient to show how some of the motor failures we hear of, and with good cars too, can be accounted for.—Yours truly,

M. C. E.

THREE OR FOUR SPEEDS.

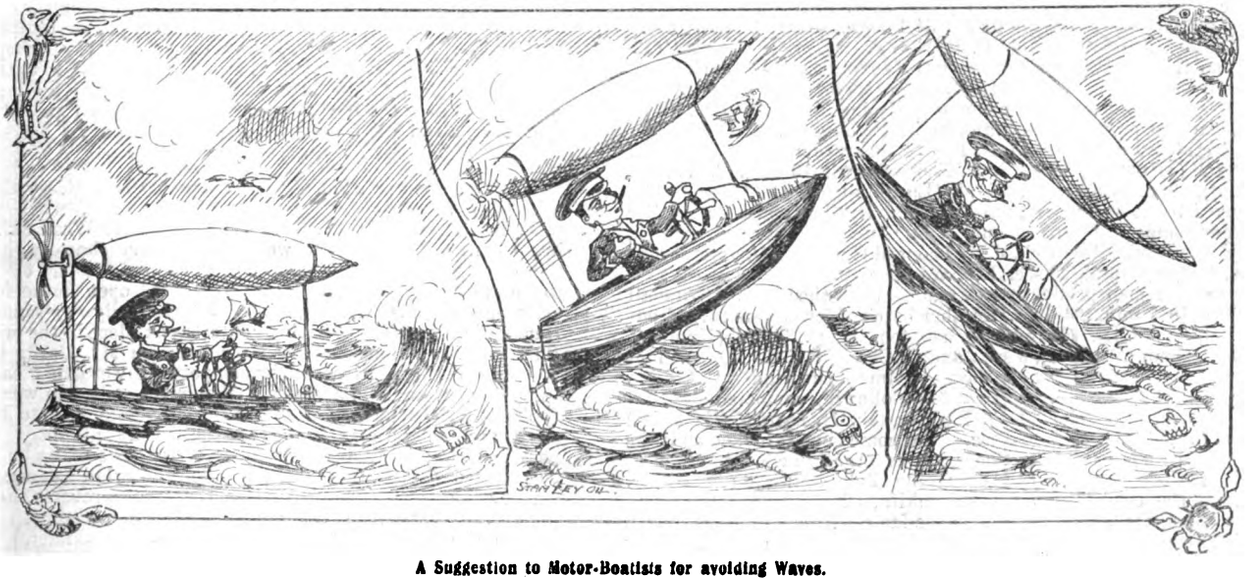
TO THE EDITOR OF *The Motor-Car Journal*.

SIR,—In some of the most recent and up-to-date automobiles three speeds have been provided instead of the more usual four. The question as to whether four speeds are necessary is an interesting one, so I will give my views in the hope that other readers of the *Journal* will give theirs. A three-speed car should be so geared that it will climb practically everything on its third speed. Now this will make the car perform a good average, as, although it may not be so fast as a four-speed car downhill, and perhaps on some long level stretches, it will certainly score uphill. When one considers the matter, it will be allowed that there are considerably more hills which one can rush up than rush down. Now the fourth speed on a four-speed car is only really seen to advantage on a downhill stretch or else a fairly long piece of level road, but the three-speed car will always be seen to advantage, as, its engine always having the preference, so to speak, it will always "get away" quickly. It may safely be said that a three-speed car will do as good an average as a four-speed unless the road chosen is absolutely flat or downhill the whole way.—Yours truly,

EXCELSIOR.

THE HORSE-POWER OF PETROL MOTORS.

TO THE EDITOR OF *The Motor-Car Journal*.



SIR,—The question of the rating or overrating petrol motors seems to be a burning one, and some active body could do the automobile movement a great service by organising a series of brake tests. The services of several competent independent engineers could be engaged, and suitable testing apparatus installed at a nominal outlay, and the results should prove highly instructive, not only to prospective purchasers, but to the technical men of the industry as well. Such tests would counteract the present perverse tendency of overrating motors, and if, as might be expected, some of the firms would not enter for the tests, private owners could be induced to lend their cars for the purpose. The tests should not only bear upon the maximum power obtainable at any speed, but also upon the power at different speeds below that of maximum power, and in the report of the results a minute description of the engine should be given, and dimensions of its various essential parts, such as valves, compression space, &c., so as to prevent the possibility of misjudging the results.

If the tests were properly carried out the results would undoubtedly be given the greatest publicity in the Press, and the manufacturers who rate their machines conservatively would benefit accordingly. Such tests were carried out in France some four years ago, and proved very successful.—Yours truly,

A. F. GLOVER.

PUNCTURE PROOF BANDS.—"Irish" writes:—"Will some of your readers kindly tell me if "puncture-proof" bands will prevent punctures, and also can a car travel at a quicker rate if these bands are attached to the back wheels? If reply is in affirmative, then whose make is considered the most efficient?"

CLARK'S EJECTOR COOLER.—Replying to several correspondents, full particulars of Clark's Ejector cooler for air cooled motor-cycles, illustrated in the last issue of the *Journal*, can be obtained from Mr. F. L. Anderson, 1, Furnival Street, London, E.C.

A Suggestion to Motor-Boatists for avoiding Waves.

Digitized by Google

MOTOR-CYCLE RACING AT THE CRYSTAL PALACE.

THE annual race meeting of the Auto-Cycle Club took place at the Crystal Palace on Saturday in dull and showery weather. A large crowd gathered together on the bank on the north side of the track. The first event of the day was a one-hour scratch race for the "Motor-Cycle" Cup, limited to motor-bicycles with engines having a total capacity in which the diameter in mm., multiplied by the diameter in mm., multiplied by the stroke in mm., does not exceed 343,000, that is 70 by 70, such machines not to exceed 114 lbs. in weight. Of the ten entries for this event seven faced the starter, including J. F. Crundall, the holder of the cup. Unfortunately the race was marred by a serious accident. Chase, on a Chase, and Bennett, on a Kerry, were riding close together when the latter appeared to wobble, and, touching the wheel of Chase's machine, fell. Bent, on a Minerva, was close on behind, and, in endeavouring to miss Bennett, ran wide and collided with the rails at the banking. He was hurled off his machine and badly cut about the head and body. The ambulance corps, which was on the ground, was quickly on the spot, and the injured man was rapidly conveyed to Norwood Hospital. Chase, after riding 22 2-3 miles in 34 min. 9 1-5 sec., retired. Crundall was easily first on his Humber, and maintained his lead to the end, the result being J. F. Crundall (Humber), 42 miles 1,390 yards, first; C. Collier (Matchless), 39 miles 1,056 yards, second; B. Yates (Humber), 38 miles 80 yards, third.

The five miles handicap for the *Motor-Car Journal* cup brought out the largest number of entries. The event, which was open to motor-bicycles with engines having a total capacity in which the dimeter in mm., multiplied by the diameter in mm., multipled by the stroke in mm., does not exceed 440,000, machines not to exceed 170 lbs. in weight, was run off in five heats and a final, in which the fastest loser was allowed to compete. The cup was won last year by J. J. Leonard, who on a Humber covered the five miles in 6 min. 54 4-5 sec.. Heat 1 brought out S. C. Holloway (Minerva) scratch, C. E. E. Smith (Humber) 5 sec., C. B. Franklin, an Irish rider of some promise (F.N.), 5 sec., D. R. Clark (New Centaur), 10 sec., and J. Haslam (Lily), 15 sec. The latter only covered about 200 yards when his belt came off, forcing him to retire. The winner of the heat proved to be Franklin, his time being 7 min. 16 4-5 sec. Heat 2 brought out five more riders, F. E. Barker (Chater Lea), scratch, R. W. Ayton (Triumph), 5 sec., S. A. East (Shaw), 10 sec., E. Varney (Crownfield), 10 sec., and H. A. Dipple (Lurquin-Coudert), 15 sec. The latter proved to be the victor, finishing first in 6 min. 58 4-5 sec. For Heat 3 four competitors turned out, J. F. Crundall (Humber), scratch, J. Perkins (Crownfield) scratch, J. J. Leonard (Lurquin-Coudert) 5 sec., and A. A. Chase (Chase), 20 sec. Leonard gave up at the end of the first lap; the scratch men gradually overhauled the other riders, Crundall finishing first in 7 min. 2 4-5 sec. Another batch of four riders turned out for Heat 4, C. Collier (Matchless), scratch, H. C. Tyler (Humber), 5 sec., W. W. Genn (Minerva), 5 sec., and C. Chapple (F.N.), 10 sec. This heat proved to be the fastest of the day, the time of the winner, C. Collier, being only 6 min. 37 2-5 sec. In Heat 5 the following competed:—F. W. (Chase), scratch, A. Tyler (J. A. P.), scratch, H. Martin (Excelsior) 8 sec., and B. Yates (Humber), 5 sec. For some time it looked as if the event would prove a victory for Chase, but eventually he had to retire, as did also Yates, the winner of the heat being Tyler; time 6 min. 44 sec. In the final the competitors were Franklin, Dipple, Crundall, Collier, Tyler and Genn, the latter starting as the fastest loser. The race proved a tussle between Collier and Crundall, the former gradually drawing away and winning by 80 yards. The result being:—C. Collier, scratch, first; J. F. Crundall, scratch, second; C. B. Franklin, 5 sec. start, third. Time, 7 min. 3 2-5 sec. The *Motor-Car Journal* Cup is thus now secured by Mr. G. Collier, who rode a "Matchless" machine made by Messrs. Collier and Sons, of Plumstead, the engine being a De Dion. The third event of the programme consisted of a series of mile time trials with a flying start for the "Automotor Journal" cup, open to motor-bicycles with engines having a total capacity in which the diameter in mm., multiplied by the diameter in mm., multiplied by the stroke in mm., does not exceed 440,000, that is 76 by 76. Machines not to exceed 170 lb. in weight. Out of the nineteen entries fourteen competed, the result being C. Collier (Matchless), 1 min. 15 sec., first; W. W. Genn (Minerva), 1 min. 16 3-5 sec., second; H. Martin (Excelsior), 1 min. 17 3-5 sec., third. The times were taken by Mr. A. V. Ebblewhite, while Prof. C. V. Boys and Mr. J. Lyons Sampson acted as technical judges.

Photo by] The Auto-Cycle Club's Meeting.—The Start of the Hour Race. *[Russell and Sons.*

CLUBS AND ASSOCIATIONS.

NOTTINGHAM.

LEAVING Nottingham at eight o'clock on Sunday morning, Mr. Ross-Browne made an effort to win the gold medal offered by the club for the longest non-stop run. He put up a total of 257 miles against Mr. C. Hardy's 153. Proceeding *via* Newark he ran on to Lincoln and back to Newark. Thence up to Doncaster, returning through Worksop and Mansfield to Nottingham. Then on to Newark once more and about eight miles out on the Lincoln road; then back again and up to Doncaster, finally stopping his engine upon reaching Nottingham again late at night. On returning to Nottingham the first time one of the exhaust valves broke. Mr. Browne's mechanician sought to repair it, but was obliged to give it up. Thereupon Mr. Browne himself tackled it. The bonnet was removed and held in the car by the official observer (Mr. Charles Perry), and Mr. Browne, sitting on the radiators, successfully overcame the trouble. The road wheels of the car were kept running all the time, and it took one hour and forty minutes to cover the twenty-one miles between Nottingham and Newark. When running on towards Lincoln the cap of the valve separated, and was repaired by the aid of tyre lever, a nut and a bolt—all clamped together.

LINCOLNSHIRE.

THE last competition of the season in connection with the Lincolnshire Club took place on Thursday of last week, when the members were invited by Mr. W. Garfit, M.P., to visit West Skirbeck House, his seat near Boston. The weather was very showery, and instead of there being sixty cars, as was expected, only about twenty ventured to put in an appearance. Mr. Garfit held open house for the entertainment of his visitors, and he personally welcomed all comers. During the afternoon a driving contest took place in the private grounds. This was for a handsome motor clock which Mr. Garfit offered to the winner. The conditions of the competition were that each car should carry one passenger in addition to the driver, and a run was made through the park and back; on the way the park gate had to be opened and shut, and as the cars had to be pulled up abruptly to allow the passenger to alight, it proved an effectual test of brake power. The last stages of the journey were along a winding course into Mr. Garfit's stable-yard, where it was necessary to reverse the engines and back the cars into a coach-house. The competitor doing all this in the quickest time was declared the winner. Owing to the difficult turns, the smaller cars had a much better chance than those

Digitized by Google

with a large wheel base. When the times had been analysed it transpired that Mr. C. Holland on his Baby Peugeot, and Mr. H. C. Tryon on his Buckboard had tied, each having covered the distance in 2 min. 39sec. The latter, however, did not quite comply with the conditions, and Mr. Holland consequently took the prize. Mr. Garfit, however, awarded a special prize to Mr. Tryon for his performance. The other competitors were Mr. George Linnell (Market Deeping), 10-h.p. Wolseley; Dr. South (Boston), Baby Peugeot; Mr. A. W. Holloway (Boston), Baby Peugeot; Dr. F. Husband (Crowland), 9-h.p. Wolseley; and Dr. Crompton (Benington), Baby Peugeot. Amongst those present were Major Goddard (Lincoln), Mr. H. T. Pilley, Dr. Reginald Tuxford, Mr. and Mrs. F. P. Curtis, Dr. E. H. Cragg (the Club Sec.), Mr. Chaderton-Johnson (Boston), Mr. and Mrs. Geo. Godson (Asgarby), Dr. and Mrs. Miller (Wrangle), Mr. and Mrs. T. W. Mays and party (Bourne), Dr. and Mrs. Gilpin (Bourne), Dr. and Mrs. de Beauvais (Ancaster), Mr. and Mrs. C. W. Pennell (Lincoln), Dr. G. Lewes (Lincoln), Mr. and Mrs. A. W. Holloway (Boston), Dr. Husband (Crowland). The last meet of the season will take place to-day (Saturday) at Revesby.

WOLVERHAMPTON.

ON Saturday last the Wolverhampton Automobile Club held a hill climbing competition at Gatacre Hill, Bridgnorth, the Trials Organisation Committee consisting of Messrs. T. Cureton, Geo. Evans, Wm. Owen, Trevor F. Young, and the Hon. Sec., Mr. S. R. Rhodes.

There was a good attendance of members and their friends, the times in the club handicap being given below. The first prize was a trophy of the value of £25, presented by the Star Engineering Company, to be retained by the winner until the first day of September, 1905. The trophy in the open handicap was presented by the Wolf Motor Company.

In the open handicap the times were:—

Name of Owner.	Make of Car.	H.P.	No. of Cylinders.	Time Ascent M.	S.
Meakin, Nelson ...	Mobile	8·10	2	2	24⅕
Cook, J. M.... ...	Argyll	10	2	2	6⅘
Sangster, Chas. ...	Ariel	20	4	1	16⅘
Bayliss, F. W. ...	Wolseley	20	4	1	14⅘

To prevent dust, the course, which was 800 yards long, with a total rise of 139 feet, was treated with a solution of chloride of calcium supplied by the United Alkali Company, Liverpool.

HERTFORDSHIRE.

THE Committee of the Hertfordshire Automobile Club held a meeting on Thursday, last week, for the purpose of passing the official times of the open hill-climbing competition held by the Club on Aston Hill, Tring, on the 10th ult. In consequence of steam and petrol cars being run together in the one class, the handicaps required very careful checking, with the following result:—

Car.	Entered by	Time on Hill. min.	sec.
10-h.p. White ...	F. Coleman	2	31 1-5
10-h.p. White ...	Capt. Fulton, R.A. ...	2	50 2-5

7-h.p. Alldays ...	A. Pemsel	5	28 4-5
8-h.p. Crypto ...	A. Hudden	6	50 4-5

At the conclusion of the proceedings the Committee unanimously passed a hearty vote of thanks to the Hon. Secretary, Mr. W. Whittall,

Count Thun-Hohenstein on his 8-h.p. Wyner Car. The Count commands one of the warships of the Austrian Navy, and carries the vehicle on board, so that he may use it at ports of call.

[*Allgemeine Automobil Zeitung.*

for the excellent manner in which he carried out the organisation and arrangement of the event.

On Saturday last the club held a very successful meet at Hatfield. In spite of the unpromising weather outlook some twenty members and friends turned up at the rendezvous, the Red Lion Hotel, where an excellent tea was served.

POLICE TRAPS.

AT Norman Cross the police are again timing motorists.

POLICE traps have lately been reported in the Colchester, Chelmsford and Maldon districts of Essex.

THE Portsmouth road at Kingston is being carefully watched by the police for speedy motorists.

NEAR Cowfold, on the road from the Metropolis to Brighton, motorists should be on the alert for a trap.

AT Selby (Yorks) the police have a measured quarter of a mile prepared for the capture of unsuspecting motorists. Castleford, too, is a dangerous district.

CASES DISMISSED.

AT Norman Cross, Huntingdonshire, James Garrett, driver to Mr. J. G. Robinson, of Cragdale, Settle, was summoned for driving a motor-car on the highway at a speed exceeding twenty miles an hour. Mr. V. G. Stapleton, of Stamford, appeared for the defendant. Two constables gave evidence for the prosecution, and admitted that when they took the measurement they were in a by-lane 600 yards away. After taking their time they walked down the lane into the main road in time to see the motorist finish the measured distance. Both witnesses stated in cross-examination that no notice was given to the driver that they intended to prosecute him. Mr. Stapleton thereupon raised an objection under Section 9, Sub-section 2, of the Motor Act against the prosecution, because no notice of intended prosecution had been given at the time. The magistrates, after considering in private, decided in favour of Mr. Stapleton's objection, and dismissed the case.

AT Hatfield Police Court, Dr. John Potter, defended by Mr. Firth, was summoned on the 26th ult. for driving his motor-car at Hatfield on the 28th August last furiously, so as to endanger the lives and limbs of the passengers on the highway. From the evidence it appeared that Dr. Potter, accompanied by Dr. Dow and Mr. McDougall, were driving through Hatfield to London in the evening, and when outside Hatfield they came into collision with a wagonette containing six people, including the driver. The bench dismissed the case.

A DRIVER'S NEGLIGENCE—EMPLOYER'S LIABILITY.

A POINT of interest to motorists was raised in a case which came before Judge Stonor, on Monday, at Marylebone County Court. The plaintiff, James Murphy, 34, Winchester Street, King's Cross, W., sought to recover £25 from Mr. A. M. Abrahams, 16, Upper Hamilton Place, Kilburn, N.W., the claim being in respect of personal injuries said to have been sustained owing to negligence on the part of defendant's chauffeur.

From the evidence it appeared that as the plaintiff was driving a cab along the Mall, S.W., the defendant's chauffeur, driving his master's motor-car on the wrong side of the road, dashed into the cab, seriously injuring the plaintiff. This happened at about a quarter to nine in the evening. The defendant stated that he left his chauffeur at about half-past six that evening, and that the man should then have taken the car to the stable close by. It appeared, however, that the chauffeur kept the car out all the evening without permission, and after bringing the car back to the stable, disappeared.

Counsel for the plaintiff submitted that the defendant was liable in respect of the chauffeur's negligence which caused the accident, even though the man was not at the time acting in accordance with his instructions. Several cases were referred to in support of the submission.

Counsel for the defendant contended that as the chauffeur, at the time of the accident, was not engaged in the ordinary course of his employment, the defendant could not be held liable for the man's negligence.

His Honour agreed with this contention, and gave judgment for the defendant, but allowed no costs.

CASES AGAINST MOTORISTS.

Place.	Summoned for	Fine.
Lewes	Failing to produce his motor driver's licence within reasonable time for purposes of endorsement	14s., etc.
„	Driving motor-car without being licensed	20s., etc.

THE

Motor-Car Journal.

VOL. VI.] LONDON, SATURDAY, OCTOBER 8, 1904. [No. 292.

Published Weekly by CORDINGLEY & CO., 39 & 40, Shoe Lane, London, E.C.

COMMENTS.

SEVEN hours have been occupied by the Local Government Board Inspector in an inquiry at Kingston having reference to an application by the Town Council of that place to restrict the speed of motor-cars in the borough to ten miles an hour, and to prohibit motorists from using Bank Lane, a roadway leading to the river. Major Macaulay, the borough surveyor of Kingston, dealing with the roads giving approach to the town, said that the centre of Kingston was only 16 ft. 9 in. In one part the main road to the borough from Richmond was only 18 ft. 8 in., while the Coombe Road entrance to Kingston from Malden was 18 ft. 8 in. wide at one point. The Richmond Park entrance to Kingston was 22 ft. 5 in. wide and the Cambridge Road entrance to the borough was 15 ft. 7 in. At Thames Street, opposite Bishop's Hall, the width of the roadway was but 16 ft. 10 in., and the Church Street entrance to the market-place was 17 ft. 10 in. As to Bank Lane, that was a road 193 yards long leading to the river which had no footpaths, its width varying from 16 ft. to 13 ft. 2 in. At present two vehicles were just able to pass each other, and the road was quite unfit for motor traffic. Altogether during the past twelve years the Corporation had spent between £30,000 and £60,000 in road widenings and improvements. The figures given by Major Macaulay with reference to the width of the streets in Kingston should be enough, we feel, to compel the council to be more liberal in widening its streets.

◆ ◆ ◆

Traffic in the Town.

SUB-DIVISIONAL Inspector Brice, who is in charge of the police at Kingston, said that on Sunday, August 10th, at three different points in the borough, which caught all the traffic, observation was kept on the vehicles. From 10 a.m. to 10 p.m. 472 motor-vehicles, 7,216 cycles, and 1,249 other conveyances passed through the town. That, too, was rather below the usual average for a Sunday, during which there was but little local traffic. The number of motor prosecutions in the borough during 1903 was eleven, and this year up to the present there had been nine cases, and there were six others still pending. During the present year thirty accidents and collisions in which motor-cars were concerned occurred in the borough. Included in the number was one fatal accident, and eleven persons were injured. And yet, despite that state of things, he had never had occasion to report to the Commissioner that the present powers under the Act were inadequate to deal with motor-car traffic in the borough

Why Restrict to 10 miles an hour?

SUCH was all the evidence that could be brought in favour of the application. On the other hand, Mr. E. K. Purchase did not consider Bank Lane a dangerous spot; Mr. G. T. Langridge pointed out that the imposition of a ten mile limit would lead to a congestion of traffic; Dr. W. Finny, an ex-Mayor of the Borough, thought such a limit was not desirable; Dr. O. Coleman, the senior medical practitioner in the district, who uses a motor-car in his daily practice, objected to the general application of such a rule; Colonel Fairtlough and Mr. R. W. Buttemer voiced the opposition of the West Surrey Automobile Club, and Messrs. T. Jays, P. Willis and R. H. Horsman having given evidence against the application, Mr. Rees Jeffreys said that in his opinion the Corporation should erect warning boards at dangerous corners and places instead of asking for the speed limit to be restricted. The decision of the Inspector in the case of Kingston, as well as in that of the City of London, is anxiously awaited.

◆ ◆ ◆

Travel in London.

THE London County Council are evidently fully alive to the changes that are coming along in street locomotion in the metropolis. At Tuesday's meeting Mr. Allen Baker, replying to questions from members, said the experience of several provincial counties did not lead him to believe that the motor-omnibuses which will shortly be seen in London streets would offer any serious opposition to the Councils tramways. In the event, however, of such omnibuses being put on the Council's horsed tramway routes, steps would be taken to see whether motors could not be used on the horsed tramcars, so as to compete with the opposition. All this rivalry will tend to the acceleration of speed in London, with consequent economy of time to business people.

◆ ◆ ◆

The Blackpool Races.

COLONEL MARK MAYHEW has been visiting Blackpool to inspect the track for the proposed races on the 14th and 15th inst. He has returned very favourably impressed with the course that is proposed for the events, and there will be a really representative entry of English automobiles. It is recognised that the proposed meeting is an added attraction at the end of the season for Blackpool, and apparently some little jealousy has been aroused in Southport in connection with the matter; but it must be remembered that motorists cannot be expected always to go to the same place, and, whilst the number of racing men is necessarily somewhat limited, the real chance of success for these seaside meetings is to hold them at different places. Thus those participating are given some variety of scenery. After all, the excitement of a motor-car race does not last long, and were it not for the opportunities for social intercourse that are created by such meetings, we do not think motorists would be so keen about them.

Digitized by Google

The Programme of the Meet.

THE meeting will take place under the auspices of the Automobile Club, and the trials will be timed by their official timekeepers, but the whole of the organisation is being carried out by a local committee. The promenade shown in the photograph is undoubtedly a fine racing track, as it is quite straight, absolutely flat, and with a magnificent surface. The programme consists of races over a standing mile, and also over a flying kilometre; in the case of the latter a very great length, in which the cars will be able to get up speed, will be provided. There are promises already of a considerable number of the big racing cars, and the local committee trust that they will receive good support in the way of entries for all classes. The sections for the touring cars are for touring cars pure and simple—that is to say, for cars which have been built for touring vehicles, not got up specially for the occasion with racing bodies or similar equipment, and they must be provided with lamps and mud-guards, representing, in fact, the car as used upon the road. By having the classes arranged for both the standing mile and the flying kilometre, an advantage is being offered to many drivers in that they will be able to have a second run with a flying start and not be knocked out at once by their inability, perhaps, or by their misfortune to get away their car quickly from the start.

The Blackpool Speed Trials. View of the Promenade on which the competition will be held.

◆ ◆ ◆

Some Entries.

THE entries are thoroughly representative, and will include at least two racing Darracqs, a De Dietrich, the Hon. C. S. Rolls' 100-h.p. Mors; the six-cylindered and other Napier cars, a 90-h.p. Mercedes and several "Sixties" of the same type, a 40-h.p. Bollee to say nothing of the Crossley, Daimler, Wolseley, Speedwell, Gardner-Serpollet and other vehicles in which the public interest is keen. In fact, it would appear that the forthcoming event will be a battle of the giants, and some record times should be chronicled. Mr. E. Shrapnell Smith will act as starter.

◆ ◆ ◆

Haulage by Road.

AT the Dairy Show at the Agricultural Hall, London, the "Jones" Haulage Syndicate have been showing the Londonderry steam wagon which made a non-stop run from Seaham Harbour to London, as recorded in the *Journal* of July 2nd last. For this vehicle the Syndicate have secured the agency for the Midlands as well as for Ireland and Wales, and they are also using it in their work as road carriers and haulage contractors. A 7-h.p. petrol-driven lorry, fitted with Dougill's friction drive and capable of carrying 30 cwt. at a speed of ten to fifteen miles an hour, has also been on their stand. They are now organising a system of haulage by road on regular routes, of which runs from Birmingham to Bristol, Manchester to Birmingham, and Birmingham to London are already in operation. Possessing facilities for the prompt handling of produce, they have only the innate prejudice of the farmer to wear down to ensure much agricultural traffic. The transport of goods for many other trades is already secured.

◆ ◆ ◆

Tyres for Motor Vehicles.

THAT the last word has not yet been said with regard to tyres for motor vehicles is evident from the many letters we receive from motorists expressing dissatisfaction with the existing forms. Many automobilists have been so unfortunate in their experiences with pneumatic tyres that they have abandoned them in favour of solid rubber until such times as a tyre shall be produced possessing all the advantages of the pneumatic tyre with none of its drawbacks. Many minds are at work on the knotty problem, and it is reasonable to assume that sooner or later the labour of at least some of these experimentalists should bring forth a successful solution. Among those who are devoting attention to the subject is Mr. W. Meadows, of Brixton, who has produced a pneumatic tyre claimed to give all the resiliency of the usual form, with the additional advantage of being non-puncturable.

◆ ◆ ◆

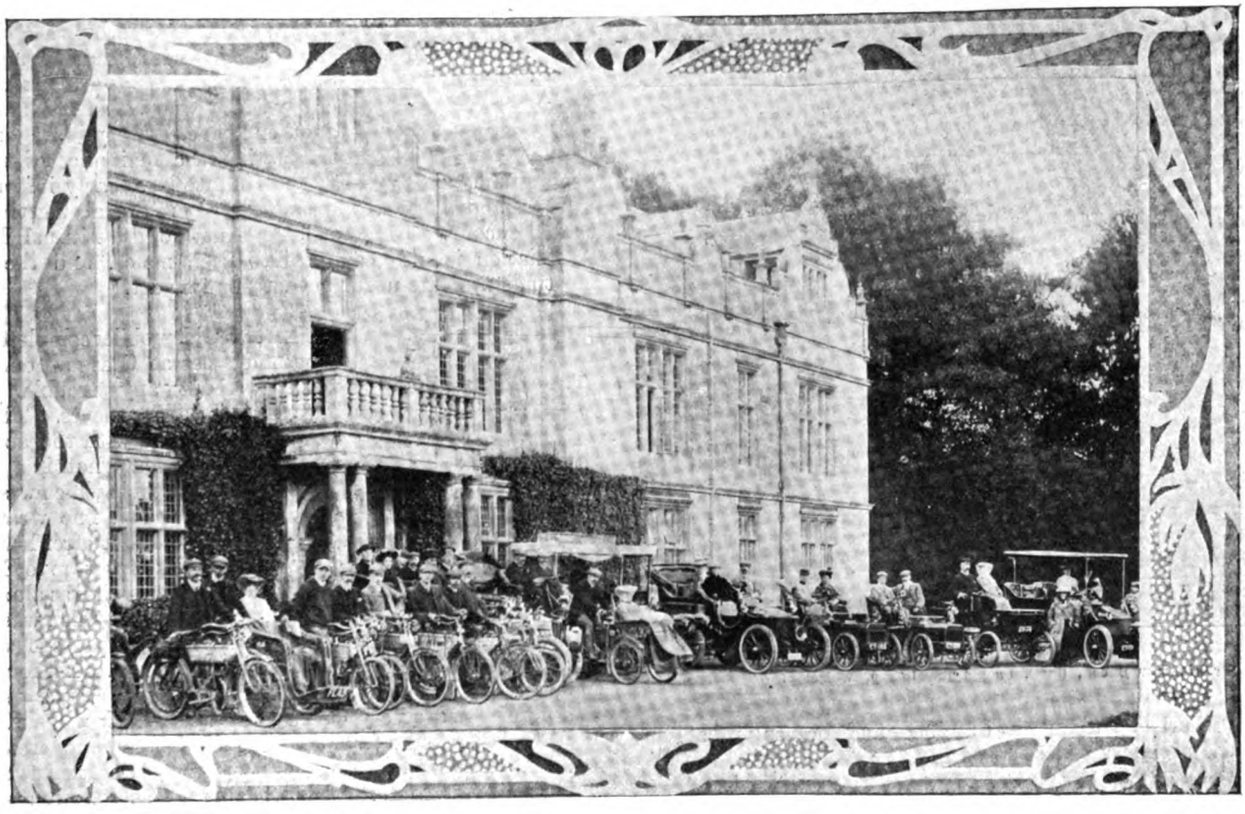
A New Idea in Tyres.

WE had an opportunity the other day of inspecting the specimen tyre which Mr. Meadows has had made, and it may first be mentioned that the rim is somewhat wider than usual in order to accommodate two inner tubes arranged side by side, he preferring to have his air cushion formed by two small tubes instead of one large one. No rubber outer cover is used to protect the inner tubes, or as a tread, its place being taken by a series of segments. The inner face of the segments is provided with two semicircular grooves separated by a ridge, so that they lie close on the two air tubes; the segments may be of thin steel or of wood with a steel tread, and are held in position by means of a long central bolt which passes between the two air tubes and through the wooden felloe of the wheel, being held in

Digitized by Google

place by nuts. The treads, of which there are usually twelve to each wheel, are so arranged that there is normally a space of about a quarter of an inch between each, the gap being filled by a rubber insertion, this arrangement being adopted to allow the necessary movement to the treads, which, as will be readily understood, are forced slightly inwards as they come in contact with the ground, the bolts being of slightly less diameter than the holes in the felloe to allow of this. The treads extend over the edges of the rim, so entirely shielding the air tubes from puncture, while, in order to protect the latter from the effects of wet and mud, they are enclosed in a stout waterproof casing, provided with small holes through which the bolts are inserted. The outer faces of the treads can be of any desired form, either flat or resembling that of a twin solid tyre; the latter is the form recommended by the inventor, as it is one which considerably reduces the liability to side slip. The new tyre, which is more especially intended for use on public-service and commercial vehicles, is certainly of simple construction, and should not be very costly to manufacture, while the treads can be easily and cheaply renewed in case of wear. Altogether the idea is one which strikes us favourably, and we look forward with interest to an actual test of the tyre on a motor vehicle.

◆ ◆ ◆



Non-Stop Motor Record.

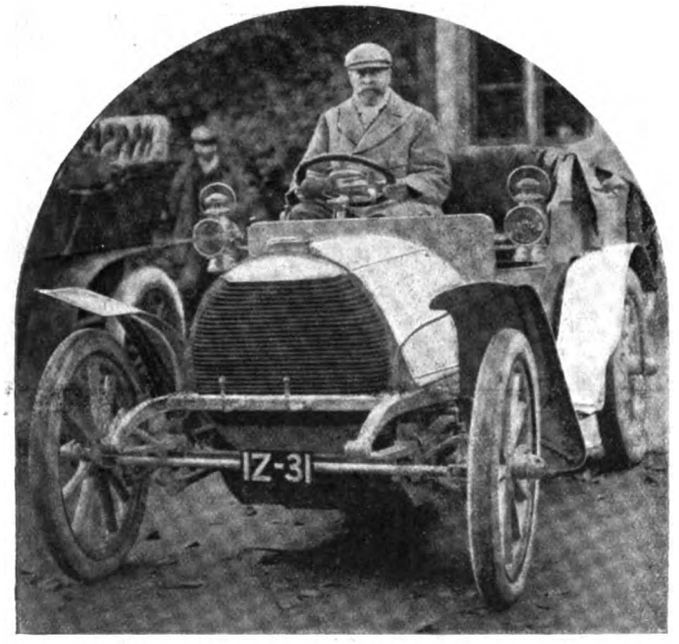
SHORTLY before half-past ten on Saturday night a travel-stained automobile was driven into the London Hippodrome by Mr. Archibald Ford. On the 23rd ult. the driver started on a long journey, and during the course of slightly less than 204 hours covered a distance of 2,391 miles without stopping the engines of his 15-h.p. Darracq car, thus beating the previous British record of 2,017 miles, accomplished by Mr. D. M. Weigel. The world's record of 2,350 miles, made by Laroche in America, also went by the board. A flashlight photograph was taken of the scene at the Hippodrome, which we are able to reproduce, and in commemoration Mr. Ford received the present of a car similar in pattern to the one on which he established the fresh record. Mr. Ford arrived in London from the north, on Saturday morning, and at once started for Brighton, but he found the southern roads dangerously slippery. Shortly before reaching Brighton the car skidded upon the greasy surface, and, colliding with some strong iron railings, the front mudguard was badly damaged, while the basket containing supplies was carried right away. Everything was quickly put to rights, however, and this proved really the only accident that took place during the long trip. Mr. Ford occupied a much longer time than Mr. Weigel, and rested for several hours during the trial, the machine, of course, running throughout.

◆ ◆ ◆

The Darracq.

THE run was not without its exciting incidents. When descending Bolney Hill, during a particularly dark night, Mr. Ford's engineer took a wrong turn, and found the car within a few feet of a sheer drop of 200 or 300 feet; needless to say, he stopped in record time. On another occasion, in coming through Moseley Street, Newcastle, owing to the treacherous nature of the roads, the car skidded right round, mounted the pavement and stopped with the tonneau a few inches from a jeweller's window, much to the evident disappointment of the passers-by. The Scottish roads were several inches under water and the nights were frightfully co'd and foggy. During the entire journey the car gave absolutely no trouble, and beyond filling the tanks with petrol, water and oil, the only adjustment necessary was the cleaning and screwing up of the ignition tremblers. The tyres used were flat-tread Michelins, and the only troubles arising from these were through faulty fitting, which occasioned three nips, no punctures occurring during the whole of the long run. Mr. Ford showed remarkable confidence in the car which he selected for his record breaking journey, as that used was a standard vehicle, taken out of stock, the only addition being a secondary petrol supply to the carburettor, to allow of taking down and cleaning the gauze filter, which is fitted above the float chamber, though this was found unnecessary,

The Meet of the Northamptonshire Club at Apethorpe Hall, the Seat of the Hon. H. L. Brassey.



Digitized by Google

owing to the careful manner in which the petrol tank was filled through a specially constructed funnel.

◆ ◆ ◆

A Dublin Case.

AMONG the owners of automobiles who have lately been fined at Dublin—and there have been a great number—was Mr. A. D. Pratt, the American Consul in Dublin, who was fined for driving his motor-bicycle at an excessive speed. His solicitor said he was an American citizen, but he would not raise the point. The magistrate said that the technical point might apply to an ambassador, but hardly to a consul. Anyhow we are glad to see that he, recognising that he was in the wrong, paid his fine and went his way without raising all the pother that an official in the British service in the United States thought well to do in somewhat similar circumstances. Defendants in such cases should not seek to rely upon any technical objections which would not be allowed to prevail in the event of ordinary mortals being concerned. The attitude of the American Consul

Sir Hickman Bacon, Bart., on his new 18-h.p. Wolseley.

in the police court at Dublin was dignified, and he has probably recognised the necessity of less speed in the city.

◆ ◆ ◆

Fire and Explosion.

ON Thursday of last week a fire broke out in the motor-car shed of the Great Western Railway Company, at Helston. Repairs were being effected to the motor-mail-'bus; standing beside this vehicle was another, constructed on the Jersey principle. A jet of gas was burning at the lower end of the building, about five feet from the head of the 'bus and about five feet from the petrol tank. The driver had repaired the sparking plugs and was unscrewing the plug of the petrol tank to remove water that had accumulated there, when an explosion occurred—it is supposed through the petrol fumes being blown underneath the car to the naked gaslight. He was below the car, and as soon as the explosion occurred was covered with burning petrol. A fellow driver named Sanders went to his assistance and hurried him from the building. Sanders went back to try and save the cars, but found the body of the 'bus in flames. He then tried to get the other car out, but failed through the sliding door having become immovable. The building then took fire and other structures in the vicinity were threatened.

The Service really Suspended.

WHILST the fire was at its highest, an explosion occurred. Without the slightest warning there was a loud report, the petrol tank having been blown from its fixture on the car. It penetrated the white hot galvanised iron of the building immediately beside the permanent way, and was hurled across the roadway used by passengers and into a field opposite Weighing nearly a half-hundredweight, the tank was thrown about 200 yards, and it is fortunate that no injury attended its flight. The scene after the fire was an impressive one. The cars were complete wrecks. Everything that could be burnt was consumed in the conflagration, and all that remained were the *chassis* of both cars, twisted into fantastic shapes. Nothing except the iron fittings of the cars were left, and even these have been ruined by the intense heat. These were the vehicles that the Great Western Railway Company had used in the service between Helston and the Lizard, which they had decided was to be suspended on Saturday last, owing to the refusal of the local District Council to steam roll the roads which the cars traversed.

◆ ◆ ◆

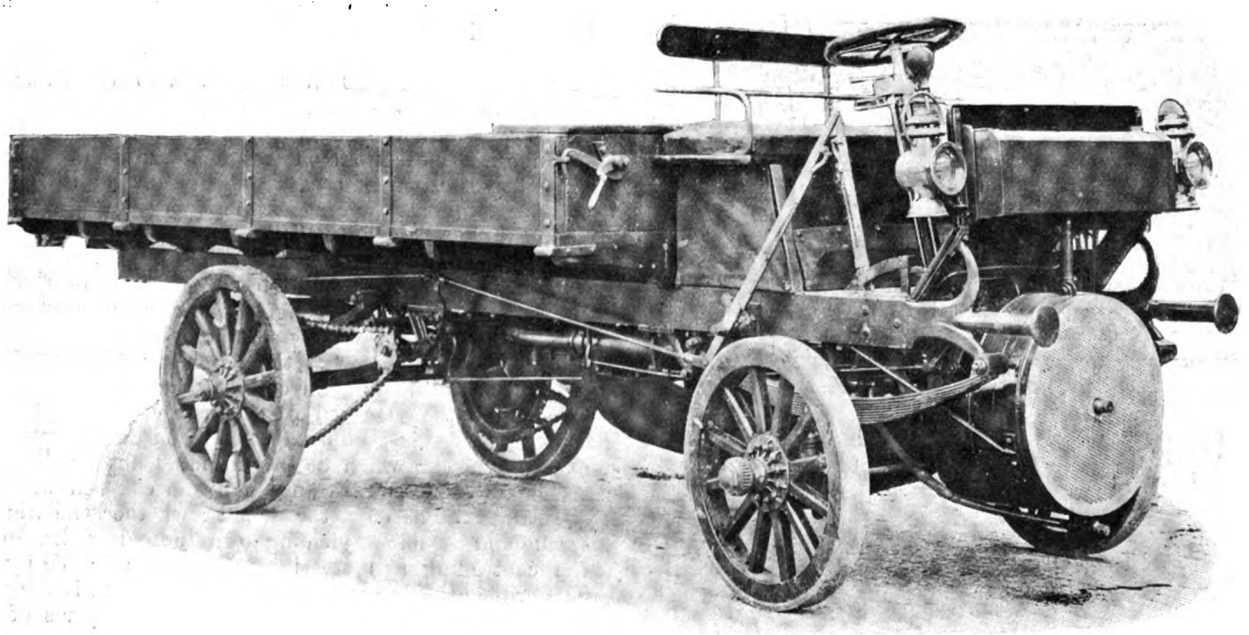
Clubs and Associations.

MANY of the provincial clubs concluded their series of outings and trips on Saturday last, as will be gathered from our "Clubs and Associations" news on another page. They are now contemplating the beginning of the winter programme, and we shall be glad to have early information of lectures and papers to be read at any provincial meetings during the forthcoming season. The Automobile Mutual Protection Association is also coming into prominence, and the monthly meetings indicate useful act vity on its part.

◆ ◆ ◆

The Oldsmobile in Ireland.

THE two Oldsmobiles completed the first thousand miles at Glasgow on Saturday week without any trouble whatever, beyond slight adjustments. The big car had a little trouble with the accumulator running down, but nothing to delay them. The cars have run up to the time table which was arranged for them right from the first day. They had fine weather until they got to Leeds and Newcastle-on-Tyne, but after leaving Newcastle it was pouring with rain all the way right up to Edinburgh, and from Edinburgh to Glasgow. On Saturday it was almost impossible to drive owing to the rain, hail and sleet, which was anything but pleasant. Neither of the cars has up to the present had a puncture, nor any trouble at all with their engines. Although having had such terrible weather the last two or three days, the drivers and observers are very fit. The run this week will end at Holyhead to-day. They take the boat on Sunday, and cross over to Dublin. The Irish route was not definitely settled at the time of going to press, but it will probably be as follows :—1st day : Dublin to Belfast. 2nd day : Belfast to Dublin. 3rd day : Dublin to Waterford. 4th day : Waterford to Cork. This gives a total distance of 412 miles for the four days. They should finish at Cork on Thursday next, and will then cross over from Cork on Friday night, arriving at Milford Haven on Saturday.



FROM Messrs. Michelin and Company, the well-known French tyre manufacturers, comes one of the most interesting books we have received for a long time past. It is entitled "The Pneumatic Tyre and the Motor Car 1894-1904," and gives a history of the development of the pneumatic tyre for motor-cars from 1894 onward. One of the illustrations shows the first pneumatic-tyred motor-car, a very crude machine with large wheels all fitted with Michelin tyres. This car started first in the Paris-Bordeaux race of 1895 and arrived ninth. The subsequent development of the tyre and its success on motor vehicles is fully described, the text being accompanied by illustrations which render the book of considerable interest and historic value. We understand that copies of the book will be sent on application to M. Wolff, 44, Bedford Row, London, W.C.

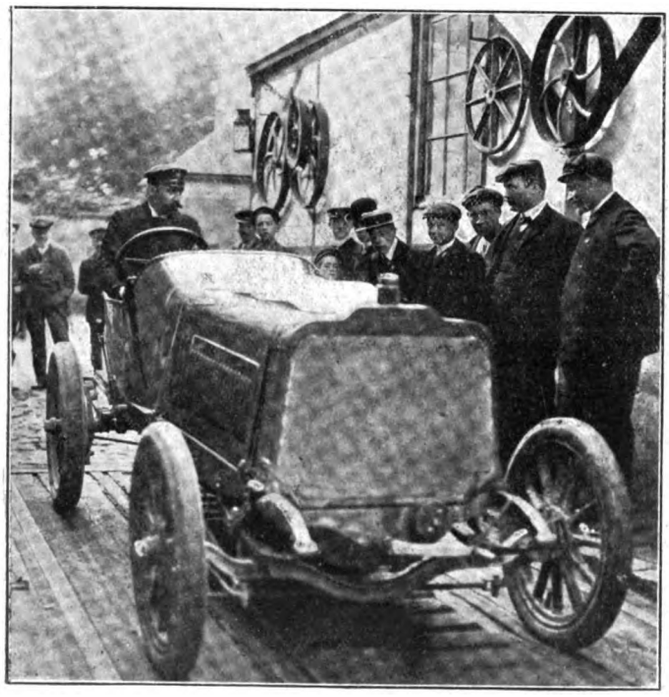
THE BEAUFORT PETROL MOTOR LORRY.

THE Beaufort Motor Company, in addition to their pleasure cars, are now entering the field of commercial vehicles, and the other day we had an opportunity of making a trial run on the heavy petrol lorry they are introducing, and of which an illustration is given herewith. The lorry is designed to carry a load of three tons; the main frame is constructed of steel of a large channel section, supported on the axles by long springs. The motive power is supplied by a twin-cylinder vertical engine, developing 12–16-h.p. The cylinders, which are 125 mm. bore by 150 mm. stroke, are in one casting. The normal speed of the engine is about 700 revolutions per minute, but can be varied between very wide limits, we ourselves having timed the engine to make as low as 100 revolutions per minute. The water circulation is maintained by a pump driven off the half-speed shaft by means of a spring device and a circular honeycomb radiator, behind which is a fan to induce a current of air through the cooler. A new departure is found in the ignition, both magneto, and the ordinary high tension with coil and battery, being provided. The magneto is of a new type, the current generated by it being passed through the coil and giving a high-tension current, utilised in the ordinary type of sparking plug, the make and break device usually required with magnetos being thus dispensed with. We are not able to give full particulars at the moment of the new magneto, but it may be mentioned that it is of a simple type, having only one winding, this being, however, of a special form; it is driven off the engine by enclosed spur gearing. The contact maker and governor are mounted on the same vertical spindle, driven by bevel gear off the half-time shaft, and are in an accessible position. The governor is adapted to act on the admission; all the valves are mechanically actuated off one cam shaft, and are so arranged that they can be removed with a minimum of trouble. A large inspection door is provided on one side of the motor, enabling the valve cams and the big ends of the connecting rods to be inspected.

Passing now to the transmission mechanism, the power is conveyed to the gear-box through a large metal-to-metal clutch, controlled by a pedal in the usual way. The gear-box is adapted to give three forward speeds of respectively 3, 7, and 10 to 12 miles per hour and a reverse, the latter being actuated by a separate foot lever. The change-speed gear is of the usual sliding pinion type, with direct drive on the top speed, a noticeable feature being the unusual width of the pinions. The main shaft, which passes through the gear-box, is also provided with very ample bearing surfaces, there being two separate ball bearings and a thrust bearing at each end. From the gear-box the power is transmitted through bevel gearing to a differential countershaft and hence by side chains to the rear road wheels. The countershaft runs on ball bearings, and provision is made for adjusting the mesh of the bevel gears without disturbing the gear-box. Radius rods are provided between the countershaft and rear axle. The latter is of the round, solid type, while the front axle is of tubular steel construction. Ample brake power is provided, a pedal controlling two band brakes on the countershaft and a pull-up hand lever, a further pair acting on the hubs of the rear road wheels, all the brakes being of the internally expanding type, entirely enclosed and so protected from dust and dirt. As a further protection against running back on hills, two sprags are supported on the rear axle. The road wheels are of a strong artillery type with wide steel tyres, although solid rubber tyres can be fitted if desired. The steering gear is of the rack and pinion type, of a construction sufficiently strong to withstand the shocks that vehicles of this type are subjected to. A sight-feet lubricator, operated by the pressure of the exhaust gases, is mounted on the dashboard, the pipes to the various bearings each being provided with a feed-regulating screw. The vehicle has a wheel-base of approximately 10 ft., and the track is 4 ft. 9 in.; the lorry platform measures 11 ft. by 6 ft. A somewhat novel departure is the provision of spring buffers to the front ends of the frame, these being clearly discernible in the illustration. The engine is located under the driver's seat, so that it occupies a minimum amount of the useful length of the frame; the seat is so made that it can quickly be lifted off to give access to the motor. Behind it is a double compartment chest, in one half of which is a most complete set of tools and spare parts, and in the other a cylindrical petrol tank having a capacity of 20 gallons, and fitted with a non-explosive device described in a recent issue of the *Journal*.



The motor, whose flexibility has already been referred to, runs very quietly, this being partially obtained by the use of a special expansion chamber for the exhaust gases, in addition to the silencer proper. The lorry, which is designed to carry its full load up gradients as steep as 1 in 6, has successfully mounted the well-known Netherall Gardens with a load of one ton. Altogether, the details of the new Beaufort lorry appear to have been most carefully thought out, and we anticipate seeing a good many of them in use at no distant date.

Digitized by Google

THE DOURDAN SPEED TRIALS.

THE mile and kilometre speed trials organised by the "Velo" were run off on the road at Dourdan on Monday last in fine weather, although the course was not in the best of condition. When the list was closed it was found that altogether fifty entries were received. The weighing-in operation took place at the works of Messrs. Gautreau, at Dourdan, on Sunday. As was mentioned in a former issue, it was decided to allow the competitors two separate trials, the mile from a standing start, and the flying kilometre, and not to have a general classification. The mile trials were run off first, the tourists leading the way, followed by the racers. Marevrelle on a Creanche was first in the under £160 class, time 2 min. 13 sec.; Gabreau on a Boyer headed the £160 to £320 section in 1 min. 57⅘ sec. Amand on a 10-h.p. Gardner-Serpollet made the best time in the £320 to £480 class (1 min. 35⅕ sec.) A Gardner-Serpollet, driven by Pelser, won the £480 to £720 category (1 min. 38⅕ sec.), while the victor in the £720 to £960 class was Gasté, who, on a Radia, covered the mile in 1 min. 21⅖ sec. Florio in the over £1,200 class did the mile on his Mercedes in 1 min. 16⅗ sec.

Baras Weighing in his Darracq Racer at Dourdan.

The best flying kilometre in the touring section was made by Gasté on the Radia (38⅕ sec.), Florio being 1⅗ sec. slower.

Coming now to the racers, the best time for the mile in the heavy car class was made by Baras on a Darracq (time, 52⅕ sec.). Dufaux on the Dufaux racer built for the 1904 Gordon Bennett race, being second in 1 min. 3⅖ sec.

In the light car class there were only two competitors, the fastest time being made by Emery on a Darracq (59⅕ sec.)

In the under fifty kilogramme motor-bicycle section Lanfranchi on a Peugeot proved to be the winner, he covering the mile in 57⅘ sec., this being a new world's record. Olieslagers on a Minerva was second in 1 min. 2⅗ sec.

The best times in the various categories in the flying kilometre trials are given below :—

Class.	Rider.	Machine.	Time. Sec.
Light Motor-bicycles	Lanfranchi	Peugeot	29⅘
Voiturettes	De la Touloubre	Darracq	36⅕
Light Cars	Emery	Darracq	29⅖
Heavy Cars	Baras	Darracq	25⅘

The times for the cars are relatively slow, being far from approaching, not to speak of lowering, the record. On the other hand Lanfranchi on his Peugeot motor-bicycle succeeded in setting up new times both for the standing mile and the flying kilometre.

HOW TO SELECT A MOTOR-CAR.

ALMOST daily we are asked by some correspondent to specify which is the best motor-car on the market. To such a question it is difficult to give a categorical answer, since personal tastes and prejudices enter so largely into the matter. As the French say, *chacun a son gout*, which means nearly the same thing as the old Latin *de gustibus non disputandum*. Still, so numerous are the various types of motor-cars now in common use, that one who has but a superficial knowledge of mechanics scarcely knows which form to select for his own purposes.

Yet there are several plain considerations which are bound to govern the most inexperienced layman in the choice of a motor-car. The use to which the vehicle will be put is a question of paramount importance. It should be determined in advance whether the car is to be employed for long-distance travelling or for town driving. The question of price comes next. The automobile industry at present is in very much the same state as was the bicycle industry in 1899. At that time a good machine was worth about £30. Now a bicycle, better constructed and more durable, can be bought for a third of the money. As in those days, it is better to purchase a car from one of the large manufacturers. The prospective automobile buyer should not hesitate to pay £20 or £30 more for a car that will perform all the services which he may expect it to do. When the amateur visits the various depots and compares different models, he should not allow himself to be wholly influenced by the exterior of the car or by the more or less happy arrangement of parts; for external appearance has little to do with mechanical construction, and can be made to suit the taste of the purchaser. What is of greater moment is the motor and co-acting mechanism. The motor constitutes the essential part of the car; everything else is largely of secondary importance. The purchaser should carefully examine the car which he has in mind and ascertain whether its motor and power-transmitting mechanism are good and adapted to the needs of the vehicle; whether the framework is strong and capable of yielding to strains and shocks, and whether the controlling and steering mechanisms are easily operated. The prime consideration, it must be repeated, is a good motor, simple in construction and operation, all the parts of which are readily accessible and easily controlled.

Light cars, of which there are several types in general use, have the advantage of being cheaper than the larger automobiles. These are eminently serviceable, not only in towns but also for long-distance travelling and touring. An important point on which the purchaser of a motor-car for country use should satisfy himself is the hill-climbing power of the vehicle submitted to him. It is not necessary that the car should take its full load up a steep hill, but it is essential for satisfactory touring that ordinary hills should be taken at a fairly good speed, and without having to shed any of its passengers. Many automobiles are so under-powered—that is, the weight of the car body and load is too great for the power of the motor—that on a hill of any length or height they cannot pull their load at a speed of more than four miles an hour. The buyer should insist on a hill-climbing test in his presence. After this purchasers would do well to take the time over a mile on the flat, to see that the car as geared for hill-climbing will also make good time on the level.

THE "General Motor Car Co., Limited," has changed its name to the "Metropolitan Engineering and General Motor Car Co., Limited." The factory is at Commonside East, Mitcham, Surrey, and the show rooms at Norbury; another depot is being opened in Royal Parade Croydon.

CONTINENTAL NOTES.

Mercedes Cars in 1905.

It is announced that an important syndicate has acquired the whole of the output of the Daimler Motoren Gesellschaft of Mercedes cars for 1905, and that they handed over immediately the whole of the production to different agencies; for instance, the German agency is given to Messrs. Flinsch and Co., of Frankfurt-am-Main; the Austrian agency to Messrs. Arnold Spitz, of Vienna; France, England and America to Mr. Charley, of Paris, who has sublet the American agency to Messrs. Allen, Halle and Co., of New York, and the British agency to Mr. Harvey du Cros, Jun. It is further reported that the 1905 output will consist of only two types, 28-32-h.p. and 35-40-h.p.

A Public Service in Roumania.

The prefectural authorities at Ilfore, Roumania, propose to organise a public motor-car service between Bucharest and Oltenitza, and are calling for offers for two vehicles; tenders are to be sent in by the 25th inst.

Public Services in Switzerland.

A company has just been formed in Zurich with the title "Mobil" Gesellschaft fur Motorwagenverkehr, to start a motor goods transport service between Zurich, Glarus, Lucerne, Aarau, and Schaffhausen. It is stated that the company has secured a number of contracts for the conveyance of goods between the places named, and that orders have been placed for four "Orion" petrol lorries, which are to be delivered in December and January next.

The Herkomer Cup for Touring Cars.

On Sunday, the 18th ult., the Bavarian Automobile Club took a drive to Landsberg on the Lech, in Upper Bavaria, in order to pay a visit to Professor Hubert von Herkomer, who, as is well known, has offered a cup for an international competition for touring cars. The cup is to be worked in silver and enamel by the great artist himself, and will not only have a high material worth but will also be a valuable piece of art. The prize cannot be competed for more than five times. Those winners who may loose the Cup in subsequent years are to receive special prizes, one valued at £100 having already been offered by Dr. Magin, of Paris, for the winner of the 1905 competition, which will take place in Munich. Further, during the meeting at Landsberg Professor von Herkomer promised to paint the portrait of each winner in the competition.

The Improvement of Hotels.

In connection with the forthcoming *Salon*, which, by the way, promises to eclipse all previous exhibitions, the French Automobile Club is organising a competitive exhibition of hotel bedrooms as they should be from the standpoint of sanitation, comfort, furniture, and fittings. There will be three grades of model rooms of first and second class hotels and country inns. Five gold medals will be awarded in this connection and £450 will be offered in prizes.

The 1905 Gordon Bennett Race.

It is possible that Italy will next year have to hold an eliminating contest to select the Italian team for the Gordon Bennett race. Three firms have notified the I.A.C. of their intention to build special racers, viz., the F.I.A.T. Company, Messrs. Matteo Ceirano and Company, and Messrs. Giovanni Cierano and Company.

Another Motor-Boat for England.

Like the Richard-Brasier "Trefle-a-Quatre" another well-known motor-boat is to fly the British flag in future, M. Vedrine's "Mercedes IV.," which won the Calais-Dover motor-boat race, having been acquired by Mr. A. L. Guinness.

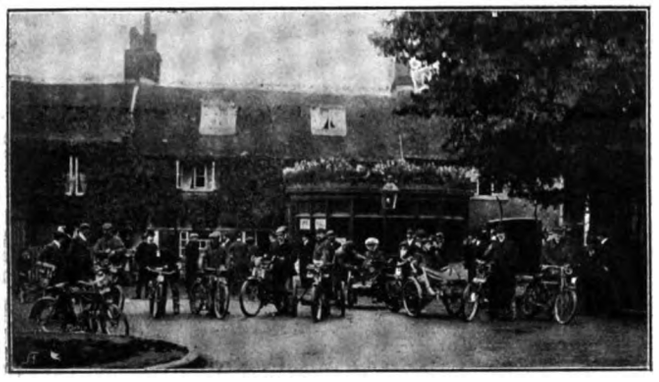
The Chateau-Thierry Hill Climb.

The hill-climbing competition for touring vehicles which the "Auto" is organising for the 23rd inst. comprises the following sections:—(1) motor-bicycles the engines of which have a maximum cylinder capacity of one-third litre (·333 cubic centimetres); (2) cars costing less than £160); (3) ditto under £350; (4) ditto under £480; (5) ditto under £720; (6) ditto under £1,000; (7) ditto under £1,400; and (8) ditto over £1,400. Except in Sections 1 and 2 there will be two classes—one for open and one for closed vehicles. The competition will take place over a mile course at Chateau-Thierry, from a standing start. All the vehicles must be in touring trim, equipped with cushions, mudguards, steps and silencers, and except in Classes 1 and 2 must carry four persons. Entries should be sent to the "Auto," the fee per vehicle up to the 21st inst. being 20 francs.

Photo by] The End of Mr. A. Ford's 2390-Mile Non-Stop at the London Hippodrome. *[Campbell-Gray.*

The A.C.F. Industrial Vehicle Competition.

The French Automobile Club has decided to postpone its industrial vehicle competition from the present month to the end of May, 1905. A wheel and tyre test is to be included in the trial.



Hill Climbing in Switzerland.

The Swiss Automobile Club held its annual hill-climbing competition on Sunday last on the road between Trelex and Saint-Cergues. The course measured six miles and included many turns, with a 5.3 per cent. grade. In the heavy car class the best time was made by M. de Ville on a 16-h.p. Rochet-Schneider, time, 17 min. 40 sec. In the light car class the fastest time was made by M. Padey on a 16-h.p. Berliot (14 min. 1 sec.). The fastest time of the day was made by M. A. Benoit on a ZL motor-bicycle, time, 12 min. 21 sec.

A MOTOR-CYCLE CONSUMPTION TEST.

THE Auto-Cycle Club's consumption trial on Saturday last was somewhat of a fiasco. The event consisted of a run from Thames Ditton, where the petrol tanks were officially filled, to Milford, *via* Ripley, Guildford and Godalming, and back; the distance out and home being 50 miles. Although only a dozen of the 28 entries put in an appearance at the start, the number must be considered satisfactory, having regard to the muddy state of the roads, due to the heavy rain of the morning

The Competitors ready to Start from the Angel at Ditton.

and of the previous day. Some time elapsed in filling up the petrol tanks, but eventually a start was made at 2.45 p.m., the competitors having to keep within sight of the official car, which set the pace. All went well until Godalming was reached on the return trip, when the car broke down, and the competitors were left to make their way back to Ditton alone. The well-known hostelry was reached just as darkness came on by all but one of the competitors, the missing rider being Mr. E. Palmer on a 3-h.p. Singer tri-car. A long weary wait ensued for the officials to arrive and refill the tanks to see how much petrol had been consumed. An hour went by, and although it was generally felt by the shivering waiting ones that the officials had had sufficient time to get back by train, no officials came. Two competitors—Mr. C. A. Smith, 2¼-h.p. Ariel tricycle, and Mr. H. Reeves, 2½-h.p. R. and P.—gave them up as a bad job, and just as others were preparing to do the same a telegram arrived, stating that they could not get back, and authorising Messrs. Lyons Sampson and Perman to make the necessary measurements. A graduated vessel and a supply of petrol being obtained, this was done, the tanks being filled right up. As, however, there was a doubt as to whether the tanks had been equally fully filled at the start or only to within a certain distance of the top, the following figures may require slight revision:—

Competitor.	Machine.	Carburettor.	Petrol consumed on 50-mile run.
H. P. Rose	2¾-h.p. Roc	Spray	42 oz.
S. Harris	1¾-h.p. F. N.-Whippet	,,	44 ,,
E. Perman	2-h.p. Seventy	,,	52 ,,
H. Martin	3-h.p. Excelsior	Surface	60 ,,
J. J. Leonard	2¾-h.p. Lurquin-Coudert	Spray	74 ,,
H. J. Densham	2½-h.p. Anglian	,,	79 ,,
H. Rignold	4½-h.p. Lagonda	,,	86 ,,
F. W. Applebee	3½-h.p. Rex	Surface	93 ,,
J. Van Hooydonk	3½-h.p. Trimo*	Spray	120 ,,

20 fluid oz. equal 1 pint. * Two-seated.

The lowest consumption was equal to about 190 miles per gallon of petrol, while the average of the single machines works out at 120 miles. Good as this is, better results would have been obtained had the roads not been in such a shocking condition. As already mentioned, two of the competitors had left before the measurements were taken, and they are consequently not included in the table.

SOME USEFUL NOTES.

THE question of changing gears is one that calls for consideration on the part of the novice. When one is able to handle the car well on the low gear, one may safely change into the next. Before changing gear the motor should be accelerated a little, the clutch withdrawn, and the gear lever moved smartly to the second speed notch. Be careful, however, not to get past the notch. If there is a "latch" on the change speed lever, it will, of course, have to be first raised before the lever can be moved. It will facilitate changing gear to raise the latch and then move the lever until the latch clears the notch, when it may be released. The latch will then be in contact with the quadrant and ready to drop into the second speed notch when the lever reaches that position. The latch, by dropping into the notch, tells when the gears are in mesh. This method of changing is much easier than when one lifts the latch and holds it clear of the quadrant until the gears are thought to be meshed and then releases the latch, which may not find its notch until the lever is moved backwards and forwards one or more times.

◆ ◆ ◆

IN cars having the "gridiron" or Mercedes type of quadrant, care must be taken that the change gear lever is not moved into the wrong slot. In going "up," if a gear is skipped, say from first to third, it will not do so much damage as if a gear is skipped in changing from a high speed to a low, say, from fourth to second. In the latter case a great strain is imposed on the clutch and transmission, as the momentum of the car is utilised in turning the motor over at an extremely high speed, and may result in breaking a gear or twisting a shaft.

◆ ◆ ◆

THE beginner should practice changing gear until this can be accomplished without looking at the quadrant, as this takes his attention from the road in front. After a little practice he will be able to change gear as well in the dark as in daylight, "feeling" by the position of the lever the speed he is on.

◆ ◆ ◆

THE following suggestion as to the proper way to hold the starting handle may be of interest to novices. Never push down, as shown in Fig. 1, when attempting to start the motor, because a "back-kick" when pushing down will generally result

Fig. 1.

Fig 2.

in a broken or sprained arm. The correct way is shown in Fig. 2. Partly grasp the handle with the four fingers of the right hand, according to the direction the engine turns, so that the crank lays across them midway between the palm and finger tips, and then pull up. If the motor should "kick," the handle will be merely pulled or slid from the fingers, and will not hurt in the least. Stand in such a position that in case of a back-kick the free end of the starting crank will not strike the legs.

HERE AND THERE.

SIX cars are in use by the Bray and co. Wicklow Motor-car Company.

ON the New Road, Ashford, Messrs. Brenchley and Co. have an establishment for the repair of automobiles.

CLOCK dials, such as are in use at many railway termini, are being adopted in connection with the motor-'bus service at Eastbourne.

The Fire at the G.W.R. Motor Shed at Helston. (See page 656).
Photo by] [A. H. Hawks.

IN future Continental motor tyres will be sold as before exclusively by the Clipper Tyre Co., and the Clipper Tyre Co. has agreed not to fix the selling prices of the motor tyres of the Continental Caoutchouc and Guttapercha Co. higher than those of the leading rival firms.

THE first automobile road race held in Western Canada was run off on Monday, the 5th ult., when five cars competed in a race from Winnipeg to Stonewall and back, a distance of forty miles. The event was won by Mr. J. K. McCulloch on a 12-h.p. Ford in 1 hour 40 minutes.

MUCH interest is taken in Egypt and the Soudan in the expected arrival at Khartoum of motor-cars for passenger service in the desert. The difficulty has been to find vehicles which are capable of travelling over the sand, but it is hoped that an early solution of this problem will be found. The Sirdar, Sir F. Wingate, was recently making experiments in this direction on the sands at a Scottish seaside resort.

ANOTHER trial of postal motor-vans is to be made in Melbourne. A private firm has consented to lend the Postmaster-General a light motor-van, capable of being used for the speedy collection of letters at the various city pillar boxes. The van will be tried for a month, and if found suitable will be the means of paving the way to the official adoption of motor vehicles for postal purposes in Victoria. A similar trial is about to be made in Perth and other big cities in Australia.

FOLLOWING up the interesting results attained by the railway coach propelled by a 100-h.p. petrol motor which is in use by the North-Eastern Railway Company, the Wolseley Company, designers of this vehicle, have produced a tram-car driven in a similar manner. The car weighs ten tons, and will carry thirty passengers and about one ton of luggage at speeds up to twenty miles an hour. It is fitted with a change-speed gear similar to a motor-car. All four wheels are driven, as in locomotive practice, to ensure sufficient grip. The motor, which is of standard Wolseley type, nominally developing 20-h.p., is expected to consume two gallons of petrol per hour when working under full load. The development of the petrol motor tram-car will be carefully watched to see how it compares with the expense of constructing, maintaining, and running electric tramways.

A GARAGE, with inspection pit, etc., has been erected in connection with the Swan Hotel, Petworth.

MR. C. LOCK, whose premises are at Stockwell Gate, Mansfield, is a practical repairer of motor-cars.

MESSRS. COURSE AND SON have a garage in Hassett Street, Bedford, from which they are letting motor-cars on hire.

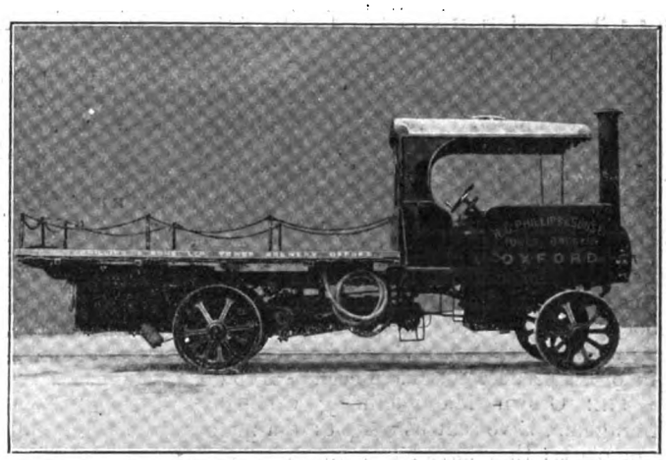
MESSRS. LETZER AND JORDAN, of London Road, Kingston-on-Thames, have been appointed district agents for the Beaufort cars.

A MOTOR-'BUS service is, we learn, being suggested for Pudsey, a Yorkshire town that is asking for Parliamentary powers to start a tramway.

THE Napier team for the 1905 British eliminating race for the Gordon Bennett Cup will consist of Messrs. Cecil Edge, J. W. Stocks, and A. E. Macdonald.

MR. W. E. TAYLOR has resigned the post of general manager of the Birmingham Motor Express Co., Limited, which has just opened another route to Harborne.

THE Morley Automobile Club held their initial run to Wakefield. Unfortunately mishaps to a couple of motor-cyclist members marred the pleasure of the outing.



MESSRS. S. F. EDGE, LIMITED, have acquired the premises of the Regent Street Garage, Limited, which will therefore be discontinued by their present proprietary after the 1st prox.

ONCE a motorist always a motorist. No one who has tasted the independence of the self-moving car and the deep diversity of pleasures it procures, turns his back on this form of locomotion.

BEFORE the official receiver, some debtors, who lately carried on business as saddlers and harness-makers at 12, Tower-hill, London, E., have attributed their failure to decline in trade, owing to the increase of motor traffic and to other causes.

THE first successful automobile race meeting in Canada was held at the Exhibition Park, Toronto, a month ago, under the auspices of the Toronto Automobile Club. The feature of the day was the exhibition riding of Barney Oldfield, who covered three miles on the half-mile track in 3 min. 57 2-5 sec.

FOR the first time in the history of the Paris Municipal pawn-shop, a motor-car was pawned with it the other day. The proprietor drove his car slowly into the courtyard, and, after satisfying the official that the machine was really his own property, he was allowed an advance on it.

The Four |Ton Steam Lorry recently supplied by the Wantage Engineering Co. to Messrs. W. G. Phillips & Sons, Ltd.

WE had a short run on a 1905 pattern two-speed Rexette the other day, and amongst other detail improvements we noticed was the fitting of elongated springs under the front seat. This made the riding very comfortable and is certainly a great improvement. The engine is very powerful and is cooled on the thermo-syphon system. An ordinary steering wheel is fitted, and ample brake power is provided. The car can climb hills of a fairly good gradient on the top speed, and can get up practically any hill on the second.

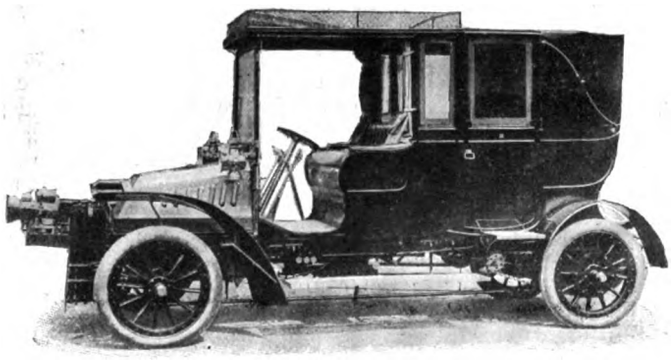
NOTICE boards, as suggested by the Motor Car Act, are to be erected at many cross roads in Perthshire.

WOULD-BE motorists are reminded that the fastest car is not the one that goes farthest in an hour, but the one that is stalled least in a year.



IT is reported that experiments are to be made in Simla with regard to employing electric motors to replace coolie labour for propelling jinrickshaws.

A MOTORIST has been aiding the police at Lowestoft by going to the station and bringing up reinforcements to the help of a couple of constables struggling with a violent prisoner.

THE Kensington Motor Company, Limited, are removing at the end of this month to new premises in Avonmore Road, Kensington, W. There they will have garage accommodation for about 100 cars.

THE LACRE MOTOR CAR COMPANY, LIMITED, have just issued a special circular relating to their device for turning any type of motor-car into a serviceable and elegant brougham. In view of the approach of the winter season, the appearance of the circular is timely.

ISSUED by the Droitwich Ratepayers' Association and the Corporation of Worcester, a new guide to the towns named and the Lower Severn Valley comes to hand, its capital illustrations and the excellent letterpress giving it an alluring power, and should do much to attract visitors to the district with which it deals.

The accompanying illustration depicts a 16-h.p. Turner-Miesse Steam Car with landau body recently built for an invalid gentleman. The vehicle is of a most comfortable and easy-running character and reflects much credit both on the constructors of the chassis—Turner's Motor Manufacturing Co., Ltd., and the body builders, Messrs. Hooper and Co.

THE Tramways Committee of the Wolverhampton Corporation are, we learn, prepared to receive particulars and approximate prices of steam and petrol motor-omnibuses suitable for service in town and suburban districts. The vehicles are to be capable of seating from thirty-two to thirty-six passengers.

PROFESSOR BAILEY, of San Francisco, an expert on metallurgy, has started on an automobile prospecting trip for Death Valley, California, where it is generally supposed there are rich mineral deposits. The district is famed as a death-trap owing to the intense heat and the absence of water. The valley has never been properly examined for gold or silver, but Professor Bailey believes that, with the assistance of his motor-car, he will accomplish what none of his predecessors have been able to do.

THE Crown Manufacturing Company, of Small Heath, Birmingham, have sent us samples of a motor repair band and a motor plaster they have lately introduced. They are designed to be used for temporarily repairing burst motor tyres on the road. After the air tube has been patched, the inside plaster, which is made of stout three-ply duck cloth, vulcanized together, is placed between the tube and cover of the tyre; it withstands the air-pressure, and prevents the cover from bulging. The outside band, which is neatly moulded with tapered edges, is then laid on the tyre cover, and the flaps are tucked inside to hold the band in position. The makers claim that the band and plaster enable a very satisfactory temporary repair to be made to any make of tyre, and as their cost is low, they form a useful addition to the tyre repair kit.

THE Chicago police have adopted a system of flash light signals with which to time motorists at night.

THE Kent County Council has purchased a Richard-Brasier car for the use of the County Surveyor.

THE North Eastern Railway Company have built a petrol motor parcel-van at their works at Gateshead.

DURING the recent manœuvres in Essex 1,500 gallons of petrol were used by the members of the Motor Volunteer Corps.

THE Bristol Wagon and Carriage Works Company, Limited, has facilities for the repair of motor-cars at their showroom in Victoria Street, Bristol.

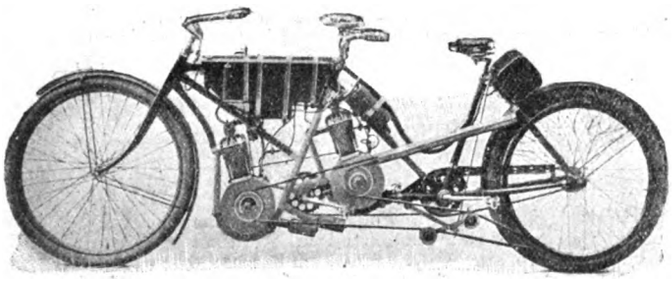
THE Kensington Rubber Company, Limited, has been registered with a capital of £1,000 to carry on the business of manufacturers of and dealers in indiarubber goods for motor-cars, etc.

THE Doherty Motor Accessories Company, Limited, Coventry, send us a circular descriptive of a set of fittings, comprising radiator and water tank, bonnet, hollowed metal dashboard, lubricating and petrol tanks, silencer and wings, they have standardised for cars of from 6 to 10-h.p.

AN appeal has been heard at the Naas Quarter Sessions in which John Tyrrell, Eadestown, appealed from the decision of the Naas magistrates at Petty Sessions, at which he was fined £2 and costs for throwing a stone at Dr. Lane-Joynt, who was in his motor-car near Kilcullen on the 28th May. The conviction was affirmed.

MESSRS. LOWE BEVAN AND CO.'S latest production in the way of hood fittings for motor-cars is a special "Facile" set for side-entrance vehicles. These fittings are made with patent oval tubes for receiving hoop sticks, and are supplied in polished steel, brass, nickel, or silver-plated; they can be also supplied fitted up complete with hoop sticks and water-proof cover, with or without curtains, to suit any shape or size of car body.

MESSRS. MATTHEW WELLS AND CO., of Manchester, have sent us a trial sample of the lubricating oil they have put on the market for petrol engines. It is known as "Wellsaline," and is made for both air and water-cooled motors and supplied either in bulk or in the usual gallon tins. They are also catering for the lubricating oil requirements of steam vehicle users and also manufacture oils and grease suitable for the gear boxes and differentials of automobiles.



CALLING in at the extensive depot of Messrs. Friswell, Limited, at Albany Street, N.W., the other day, we had an opportunity of inspecting a handsome 12-h.p. Peugeot limousine which has lately been built for Lady Beatrice Rawson. The vehicle, which is painted in red, with black lines, is upholstered in red leather. The limousine is of the detachable type, enabling the car to be readily converted into an open side entrance vehicle when desired. The little Baby Peugeot is apparently losing none of its popularity, for we noticed quite a number of them being got ready for despatch to clients in different parts of the country.

THAT the 1904 season is approaching its end is indicated by the appearance of the 1905 models of cars. Among the first of these is the 10-h.p. Motobloc, the agents for which in this country are Messrs. Montague Hawnt and Co. We had a short trip on the new vehicle the other day in company with Mr. Hawnt, in the course of which we had ample evidence that not only is it speedy on the level, but that it tackles hills with ease. So far as the engine and transmission gear is concerned the new model shows but little change, the system having given excellent results. It is in the details that improvements have been effected; the throttle, air and ignition levers are now mounted on the steering wheel, while the clutch and brake pedals are of the push forward type. The frame has been slightly lengthened, as have also the front springs. The steering bar is now located behind instead of in front of the axle; the steering pivots of the front wheels are provided with a ball bearing; the brake drums are now attached to the hubs of the rear wheels and not to the spokes of the latter, thus relieving them of strain, while another minor but useful improvement is the provision of oil holes to all the springs. The changes which have been effected are the result of experience during the past twelve months, and we look forward to the "Motobloc" giving a good account of itself during next season.

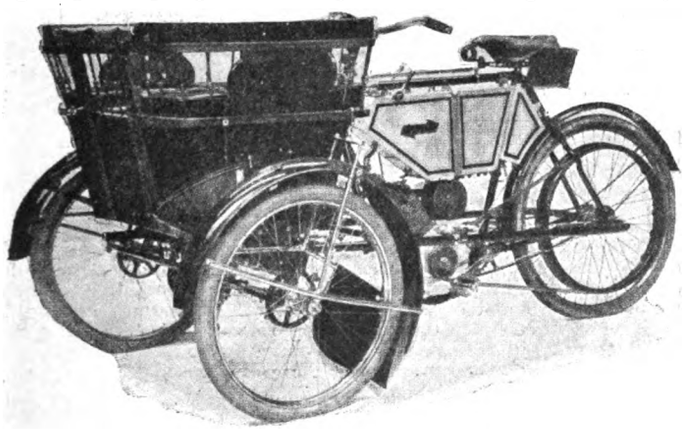
MOTOR CYCLING NEWS.



THE accompanying illustration shows a new motor-tandem recently brought out by the Wagner Cycle Company, of St. Paul, Minn., U.S.A. This tandem is equipped with two 2½-h.p. motors, With the Wagner extra seat attachment it makes a fine triplet. The petrol tank holds five quarts, sufficient for seventy-five miles running. The machine will run at speeds of from four to thirty miles per hour. Both engines are controlled by the front driver by means of a single lever, but the engines can be operated

separately, if desired. Belts are tightened simultaneously. The machine has separate carburettors, batteries, coils, silencers, etc., but the two belts for driving pass over a common pulley on the rear wheel, and are tightened by a common device. When desirable one motor can be used for propelling and the other can remain idle, or in case of one being disabled the other will always take the rider home. Pedals are provided for both riders, so that either rider can pedal when starting the motor

◆ ◆ ◆

MESSRS. MILLS AND FULFORD, of Coventry, who have for some time devoted special attention to the construction of trailing, fore and side cars for motor-cycles, have recently introduced the novel fore-car shown in the accompanying illustration. It is known as the "Governess," and has a seating capacity for two adults or four children, and as the seats are arranged one each side of the body, the driver has a clear view of the road in front of him. The illustration shows the car fitted to a motor-cycle. The body is of wood, painted and varnished, and comfortably upholstered, with a door in front and a fastener exactly on the same lines as in a horse-drawn governess car, except that entry is from the front instead of the back. It is mounted each side on long elliptical springs. The mudguards have strong tubular stays

on each side of the steering wheels, and are extended above the guards to form lamp brackets. The frame of the car is arranged so that it can be coupled up to any type of motor-cycle. All that it is necessary to do is to detach the front forks, and slide the head over the steering column of the frame. The extended members of the frame clip on to the back forks, and are provided with bushes for that purpose, which enable the members to grip either round, D or oval fork sides

◆ ◆ ◆

THE Brighton Cyclist Club held a motor-cycle hill climb on Thursday of last week on the north side of Clayton Hill, which was in every way a perfect success. There were thirteen entries, and, though the hill was thronged with people, the only drawback was the number of vehicles. The competitors were sent up the hill singly, all being got off within half an hour. The handicap was drawn up by Mr. F. Straight, of the Auto-Cycle Club. The following was the result of the handicap :—

	Start. Sec.	Actual Time. Min. sec.	Net Time. Min. sec.
1 F. H. Parsons	35	1 31	— 56
2 J. Mellison	20	1 19	— 59
3 J. Holloway	10	1 22	1 12
4 F. Thorogood	10	1 23	1 13
5 E. Le Couteur	20	1 34	1 14
6 W. Cowderoy	scratch	1 18	1 18
7 J. Best	40	2 10	1 30
8 E. W. Carter	10	1 44	1 34
9 T. Treacher	15	1 54	1 39
10 A. J. Crawford	10	1 52	1 42

F. W. Fowles, H. J. Funnell, and J. Feldwicke, 25 sec., did not start.

Cowderoy, who rode a 3½-h.p. "Cowderoy Minerva," did the fastest time, *i.e.*, 1 min. 18 sec.; Mellison, 2¾-h.p. "Bat," being next with 1 min. 19 sec., and Holloway, 3-h.p. "Holloway," third, with 1 min. 22 sec. The following assisted as officials :— Judges, Messrs. C. Dumbrell (captain) and A. W. F. Varley; starter, Mr. J. Feldwicke (president); timekeepers, Messrs. Brown and Ward; umpires, Messrs. W. Trussler, H. Butler, T. Mepham, D. A. Friend, J. Jones, H. Jarrett, and W. Shaw.

Mr. H. Rignold on his 4½-h.p. Lagonda on which he competed in the International Cup Race.

◆ ◆ ◆

THE Bristol Bicycle and Motor Club have held a hill climbing contest over a mile course with a total rise of 350 ft. Gold medals were won by Messrs. C. R. Edbrooke (3-h.p. Leader) and F. G. Tricks (3-h.p. Crabbe) for the fastest time and most meritorious performance respectively.

ALTHOUGH not yet absolutely completed, the large new works of Messrs. Clement Talbot, Limited, are open for inspection by anyone interested. A card of admission can be obtained on application in writing to the company. The huge gas engines built by Messrs. Willans and Robinson, Limited, of Rugby, which will supply the power for the new factory, were started for the first time last week, and were found satisfactory.

THE Cannstatt Mercedes, Limited, has been registered with a capital of £100, to carry on the business of manufacturers of and dealers in motors of all kinds, cycles, velocipedes, carts, wagons, vehicles, ships, boats, launches, flying machines, engines, mechanically-propelled vehicles and carriages of all kinds, engineers, machinists, &c. There will be no initial public issue, and the company has been registered without articles of association.

CORRESPONDENCE.

THE NECESSITY OF WITNESSES.

To the Editor of *The Motor-Car Journal.*

Sir,—I was driving along King Street, Hammersmith, the other day, when I noticed straight in front a woman appear from behind a tram car. She had her back towards me. I blew the horn, she at once jumped, and rushed to get out of the way of the terrible automobile, which she of course thought was travelling at sixty miles an hour and more, stumbled, and trod upon her dress and fell down upon her face. Of course great shouts and screams went up in the busy street. However, after she had cleared away her debris, I let in my clutch and drove gently away, smiling to myself.

When about fifty yards away, I heard shouts for me to stop, and a policeman came running after me, saying, "You have knocked a woman down and you must come back." I was rather amused at this, so reversed. Arriving at the great crowd that had collected, I stopped my engine, and pulled out my pocket-book to obtain witnesses' names and addresses. One gentleman came forward at once, giving me his name and address, saying "it was nothing whatever to do with me, you never struck the woman, and stopped the car short of her by about fifteen yards; in fact, it was entirely her own fault, and such persons ought not to be allowed to walk about such busy thoroughfares as Hammersmith."

Getting further into the crowd I heard a woman say, "I hate motor-cars, but I won't see them blamed for that they don't do," so I at once took this sporting lady's name and address, she saying exactly the same as the first witness. Finally the officer who stopped me came up, and apologised most humbly for having stopped me, saying he did not see the affair happen himself, but was informed by someone that I had knocked a woman down.—Yours truly,

J. Russell Sharp.

THE RULE OF THE ROAD.

To the Editor of *The Motor-Car Journal.*

Sir,—The recent smashing up of a motor-car by being wedged between two electric tram-cars again calls attention to the growing neglect of the ordinary rules of the road, either through carelessness or ignorance. With regard to passing tram-cars, there is only one side on which to pass a tram, and that is on the inside. The tram rails are laid in the centre of the road solely with the intention of allowing a convenient space on the near sides of the road for other traffic. It would be very awkward if the lines were laid on the extreme near sides of the road, leaving the centre of the road clear for other traffic. How would traffic wishing to turn into side roads, or turning out from side-roads into trammed roads, fare?

The trams, running on rails which are laid in the centre of the road, cannot deviate from their course, and in the case of a vehicle overtaking a tram, the only safe and logical course for it is to pass the tram on the inside. Should the vehicle attempt to pass on the off-side, it is immediately confronted by the traffic coming in the opposite direction, and is on its wrong side immediately it goes over beyond the centre of the road. In the event of such a vehicle running into, or being run into, by another vehicle, it is entirely to blame, being the cause of the accident through being on its wrong side of the road. The practice of passing trams on the off-side is so very common that it is a wonder more accidents do not occur. It is so very obviously wrong, even from a common-sense point of view, that it makes it even more difficult to understand why people will run such risks of accident. In the case of roads having electric standards in the centre of the road, the danger is greatly multiplied.

I write this in the interests of road users generally, as I observe that cyclists besides motorists are very great sinners in this respect.—Yours truly,

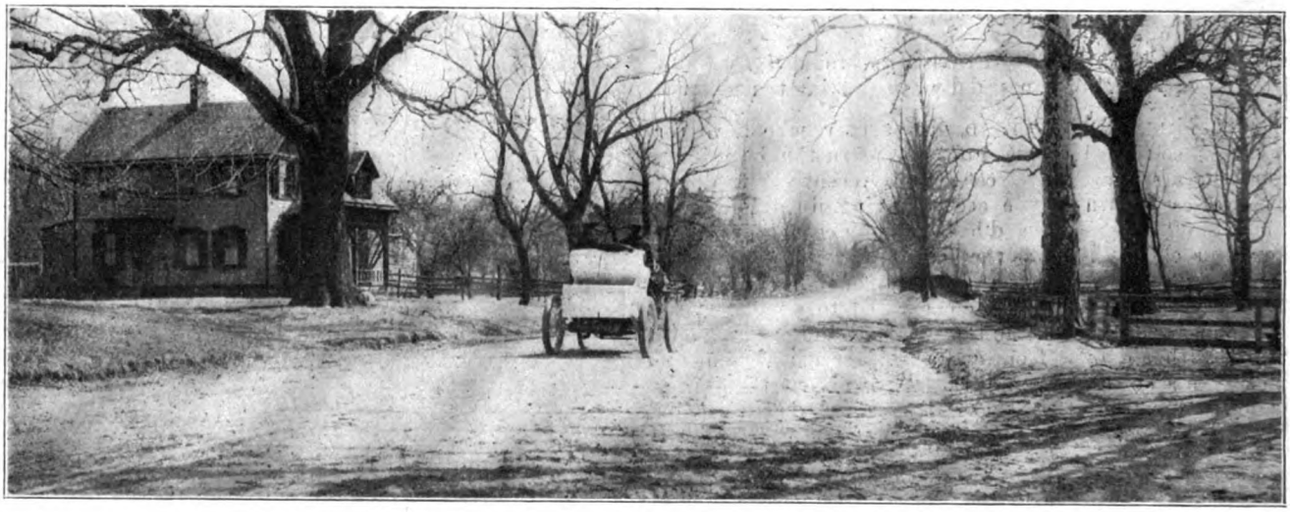
Motor Cyclist.

WHERE ARE REPAIR SHOPS WANTED.

To the Editor of *The Motor-Car Journal.*

Sir,—As a subscriber to your *Journal* I am writing to ask you if any of your readers can tell me where a repairing shop for motor-cars is required. I am thinking of starting a small business of that sort. I thought if I could get on a much-frequented main road just outside a large town there might be a chance of success for an efficient man.—Yours truly,

D. H.



A PETROL MOTOR QUERY.

To the Editor of *The Motor-Car Journal.*

Sir,—When my car has been running for a short time the engine will not stop when the ignition current is cut off, but continues to explode six or eight times, and often finishes with a loud report in the silencer. Can any of your readers tell me how I can stop this trouble? The engine is an 8-h.p. single cylinder which has run about 1,200 miles, and the sparking plug keeps clean.—Yours truly,

T. A. R.

[This trouble is without doubt due to the cylinder being foul, and could be remedied by taking it off and cleaning thoroughly; the firing is caused by the deposit in the cylinder head becoming incandescent and so firing the charge. This will continue until the heat diminishes, the engine generally coming to a stop with a back-fire.]

The Vanderbilt Cup Course.—A View near Jericho, Long Island, U.S.A.

A DE DION ENGINE QUERY.

To the Editor of *The Motor-Car Journal.*

Sir,—It is impossible to say with certainty without inspection what causes the noise which "Trentham" complains of in the last issue of the *Journal*, but I think that if he gives his engine a little more gas when he throws the top speed clutch in the noise will not occur. He will, of course, give the engine more air as the speed increases after changing.—Yours truly,

T. Marshall.

To the Editor of *The Motor-Car Journal.*

Sir,—Replying to "Trentham's" letter in the last issue of the *Journal*, I should be inclined to put the noise down to the click of the valve when closing, as invariably all engines of this type cause this clicking, especially after being run a short time. This is usually due to the wear on the gear-wheels, which practically becomes equal on either side of the teeth, especially at the point where the cam engages. If this should prove to be the trouble, it is almost unavoidable.—Yours truly,

Colin.

ARE MOTOR-CAR WHEELS STRONG ENOUGH LATERALLY.

To the Editor of *The Motor-Car Journal.*

Sir,—Referring to the letter from Mr. J. T. Ward in the *Journal* of the 24th ult., on the subject of motor-car wheels, we are much interested therein, and we note Mr. Ward has pointed out the exact

Digitized by Google

direction in which an improvement in the construction of the artillery wheels can be made. As we confine our attention to the manufacture of these wheels, and have studied the matter very closely, we some time ago came to the conclusion that what was required was a wheel which would withstand the enormous lateral strain to which it is liable to be subjected when in use on a motor-car.

Having this in view, we designed our "Twin-Spoke" artillery wheel, and, after the most exhaustive tests, we now claim to be able to supply a wheel which will withstand any ordinary strain to which it can be subjected on a car, and will also stand up in most cases—such as collisions, etc.—when an ordinary wheel would give way. We quite admit that the best hickory is an excellent material of which to construct the spokes of an artillery wheel, but at the same time we have found in practice that, if the best seasoned timber is used, the point which is of most importance is the construction of the wheel.—Yours truly,

THE ARTILLERY WHEEL WORKS, LIMITED.

TYRES.

TO THE EDITOR OF *The Motor-Car Journal*.

SIR,—Referring to "John Ansonia's" letter *re* tyres in the *Journal* of the 24th ult., I may say that I came to the conclusion some time ago that life is too short for pneumatic tyres. No doubt such are necessary for racing and high speeds, but for any speed under twenty-five miles an hour good solids are far and away better. The car, of course, requires to be built for them, and should have a long wheel base and good springs, and I think further that the chain drive and plain bearings for the wheels are advisable. With these conditions observed there is no difference as to vibration between solid tyres and pneumatics, and there is no doubt that solids raise far less dust and have far less tendency to side slip, while they are better hill-climbers.

Several motor makers now build for solid tyres, such as Wolseley, Albion, etc., and there is no doubt that the public would take to motors still more rapidly than they are doing if it were generally known that solids are comfortable and good. My car is a James and Browne fitted with Sirdar buffer solid tyres, and, after considerable experience over all kinds of roads, I am thoroughly satisfied in every way.—Yours truly,

ULOOLA.

TO THE EDITOR OF *The Motor-Car Journal*.

SIR,—Referring to your correspondent "M. B.'s" inquiry with regard to solid tyres for hill-climbing, it will interest him to know that a solid rubber tyre, properly constructed, has been proved over and over again to be a better hill-climber than a pneumatic tyre, because of the back-lash in the pneumatic tyre at a pressure at which it is inflated in the ordinary way; but, of course, this does not apply to pneumatic tyres which are pumped much harder than solid tyres for racing purposes.

Take, for example, the hill-climbing contest of the Dorset Automobile Club held this month. A 6-h.p. De Dion, fitted with Royal Sirdar-Buffer tyres, climbed the hill in 3 min. 1 sec. A similar car, fitted with pneumatic tyres, climbed the hill in 3 min. 7 sec. A 6-h.p. Siddeley fitted with pneumatics climbed it in 3 min. 4 sec. Three 8-h.p. cars, fitted with pneumatics, took from 44 to 131 seconds longer than the car tyred with these solids.—Yours truly,

J. M. MACLULICH.

TO THE EDITOR OF *The Motor-Car Journal*.

SIR,—In answer to "Perplexed's" letter in the *Journal* of the 3rd ult., I run a 20-h.p. car weighing between 18 and 19 cwts.; the Roi des Belges body will seat two in front and three behind. The size of my tyres is 870 mm. by 90 mm. When I purchased the car (in May) the two driving wheels were fitted with Dunlop tyres, which were nearly new. I had not run more than a hundred miles before one of the tyres burst just over the rim of the wheel. I put on my new spare tyre of the same make, which burst exactly in the same place as the first one within the next two hundred miles. I have now put on a Clincher-Michelin tyre with a Michelin inner tube; this I have never had the slightest cause to remove, and I have run the car I should think twice the distance of the two other tyres together. In the meantime the Dunlop of the other wheel has burst in the same place as the first two. I have put on this wheel a Clincher-Michelin tyre on which is a Pneu Herault non-skidding cover. I think the tyre bill by far the most expensive item in motoring, especially on a heavy car.

With regard to the Pneu Herault non-skidding cover I should be glad to hear of any experiences of this new device. It certainly prevents punctures and cuts of any kind whatever, but as to its non-skid powers I find that it is worse than the bare tyre. On granite sets the wheel spins round when starting the car, and when I put the slightest pressure on the brake it stops altogether and skids.—Yours truly,

TYRES.

BUTCHER BOYS.

TO THE EDITOR OF *The Motor-Car Journal*.

SIR,—I am writing respecting the dangerous way in which butchers' boys generally drive their carts, on the wrong side of the road, and swinging round the corners without regard to other traffic. There has been a serious accident in Erdington from such conduct. A gentleman coming from Glasgow along the Chester road had a collision with a butcher's cart which smashed the front of his car. Some of the occupants where seriously injured. The horse had to be shot. The boy was not hurt. This is not an isolated case. Young lads ought not to be allowed to drive such vehicles, and the sooner local authorities apply an age limit to drivers of horse-drawn vehicles the better.—Yours truly,

DANGEROUS DRIVING.

DARRACQ TROUBLES.

TO THE EDITOR OF *The Motor-Car Journal*.

SIR,—In answer to "Ignition's" letter, in the last issue of the *Journal*, *re* misfiring, I had precisely the same trouble with a 24-h.p. car. This was remedied by adjusting the throttle. Upon examining this I found that the governors entirely closed the throttle, thereby stopping all supply of mixture from going into the engine, but by adjusting this to admit a very small quantity of mixture the misfiring ceased. Trusting this may aid in overcoming "Ignition's" trouble.—Yours truly,

24-H.P. DARRACQ.

A TREMBLER QUERY AND OVERHEATING TROUBLES.

TO THE EDITOR OF *The Motor-Car Journal*.

SIR,—I should advise "Petrol" to see that his trembler is adjusted correctly to give the greatest number of revolutions without misfiring; if this is right, then examine the sparking plugs and see if they leak electrically, which will cause intermittent firing.

If "Enquirer" will shut off his throttle or governor when turning corners or slowing down, instead of switching off, he will have no explosions in the exhaust box, which is caused by passing unfired charges of gas into the silencer, which are fired in one loud explosion on switching on again.—Yours truly,

B. U. 7.

TO THE EDITOR OF *The Motor-Car Journal*.

SIR,—In reply to "Enquirer's" letter in the last issue of the *Journal*, his overheating is no doubt due to the cylinders being foul, also to slight corrosion in the water jacket. I would strongly advise the taking down of the cylinders and thoroughly cleaning the same, especially the cylinder head, which will undoubtedly be found thickly covered with black deposit. With regard to his other trouble, this can easily be remedied by omitting to switch off on going round corners. This switching off is unnecessary in driving a car, and is very seldom done, the throttle being a substitute, together with the clutch. This is also likely to put unnecessary work on the gears, as it depends entirely on the momentum of the car to again start the engine.—Yours truly,

BRIXTONIAN.

TO THE EDITOR OF *The Motor-Car Journal*.

SIR,—Referring to "Petrol's" letter in the last issue of the *Journal*, I myself would feel inclined to advise him to have his coil tested by the makers, as there seems no doubt that he has a short in the same. A high-speed trembler coil would greatly improve the running; it could be fitted to existing contact breaker and would in all probability overcome the trouble.—Yours truly,

H. J.

STEAM CARS.

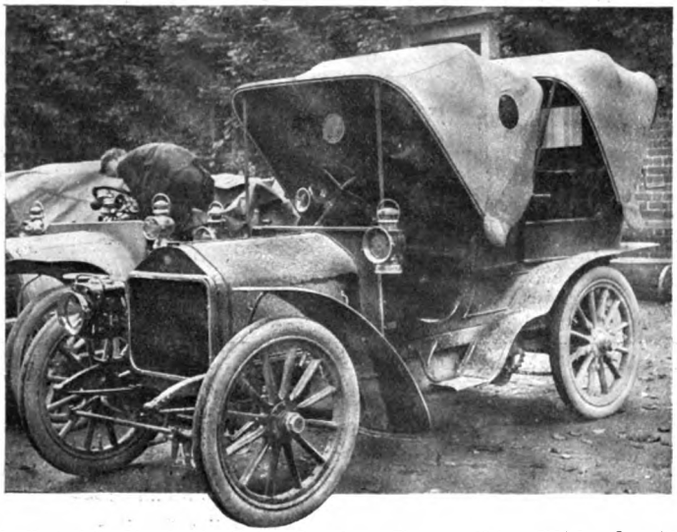
TO THE EDITOR OF *The Motor-Car Journal*.

SIR,—I have read with great interest the correspondence in your excellent *Journal* on the vexed question of steam cars, and having just completed a fortnight's holiday on my own steam car, I have ventured to offer to the general discussion a few brief remarks on my experiences.

My car is a Locomobile touring car, having a framework and running gear of great strength. The engines are "Mason" of 10-h.p., and are fitted with the Pony-Rochester automatic lubricator. The boiler is of the usual vertical fire-tube type, with superheater; it was originally fitted with a petrol burner, but I soon became convinced that petrol as a fuel was too dangerous for comfort, so had my burner adapted to burn paraffin on the Morriss system, and by this arrangement I find that I not only eliminate danger, but also get a most efficient and economical fire, one gallon of ordinary Russian paraffin sufficing for twelve miles of travelling.

My journey consisted of a run from my home in North London to Stratford-on-Avon, a stay of one day there, then a run to Chester, where I stayed for several days, during which I made trips into the surrounding country, including two into the Welsh hills. On the return journey I drove through the Vale of Llangollen to Shrewsbury,

A Non-Stop Run.



Digitized by Google

thence, *via* Bridgnorth, Kidderminster, Worcester, Evesham, Broadway, Moreton-in-Marsh, Bicester, Aylesbury, Tring and Watford, home. In all, my car covered over 500 miles. I had very bad weather on two days, on the first of which I ran through a gale of wind and rain, and was held up for a considerable time by a tree which had been blown across the road. On the second I encountered heavy rain, and had to tackle roads which were dangerously greasy; indeed, on several hills my sprag (an appliance which, by the way, I think should be fitted to all cars) saved me from disaster.

The only trouble I had with the car was a burst back tyre on the second of the wet days—the continual skidding having proved fatal to a tyre which, from the commencement, I was afraid would not last out. I had no trouble with my engines, saving the shaking off of a dust-cap on a connecting rod, the giving way of an india-rubber hose connection on the bye-pass water pipe, and the leakage of one of the gland packings towards the end of my journey—all of which defects I was easily able to put right.

The boiler steamed excellently, and I was able to deal with the big hills, and anyone who knows the country through which I passed will admit that for some of the hills the epithet "big" is but a mild one, without fear, and with invariable success. I was my own driver and mechanician throughout—my sole passenger being my wife.

I may say that I am an absolute amateur at engineering, my profession being that of medicine. I always run my car with rather a full boiler, and I find this the best course to adopt, as the superheater practically does away with any trouble from priming, should one chance to be too liberal in the allowance of water, and one is prepared for any sudden change of gradient. I cannot see why the "scorched boiler" bogey should be the popular terror that it seems to be—in my opinion it is

The Meet of the Lincolnshire Club at Revesby. The new 18-h.p. Siddeley Car with Double Hood. **(*See page* 669.)**

best avoided by (1) blowing down the boiler frequently, especially if hard water is used; (2) by regularly testing the water-gauge connections to see that they are clear; and (3) in all cases where the water level shows marked signs of falling too far, by shutting down the fire at once, and investigating the whole water system in order from the storage tank to the boiler.

I would advise the would-be purchaser of a steam car, before he buys, to acquire a simple but sound knowledge of the principles of the steam-engine, and then, having got his car, to thoroughly master its entire anatomy before he attempts to drive it. To those who suffer from acute mechanical ineptitude, I would say—"Unless you can afford to keep an engineer in your employ, leave motor-cars of all kinds alone." I must apologise for trespassing on so much of your valuable space, pleading as my excuse the hope that a little practical experience on the part of an amateur may prove of interest to those who, like myself, have a decided leaning towards the steam car.—Yours truly,

J. H.

To the Editor of *The Motor-Car Journal*.

Sir,—The question of steam versus petrol cars appears to be very properly engaging the attention of motorists, and as I have driven a steam car for about two years and also a petrol car, perhaps my experience will be of some benefit to those who are hesitating between the two.

"Faber," in your *Journal* of the 17th ult., speaks of the time that it takes to get under weigh. It certainly takes about ten to fifteen minutes to get the car under full steam pressure starting from "all cold," but in the case mentioned by your correspondent it appears that this particular car is required several times a day; in that case it certainly would not take more than three or four minutes to get up a full head of steam, and in the event of the car being required within an hour or two after it came in it would be advisable to keep the pilot light burning. The pilot light consumes no appreciable amount of petrol, and then it is possible to get steam up in from two or three minutes; I do not, therefore, consider this is a factor worth serious consideration by users of steam cars.

The various criticisms on "Wiser Man's" letter in your issue of the 24th ult. are very much to the point, but they err on the side of being too lenient, as there is no doubt that certain cars that were put on the market a few years ago have done a great deal towards ruining the steam car industry in this country. There are two or three makes of steam cars which are absolutely reliable, and it is a great pity that the strictures passed upon the steam car mentioned in your *Journal* should be held to apply to those which are so. It is not necessary to go to the heavy expense of a "White," "Miesse," or a "Serpollet" car, as there are much lower-priced reliable steam cars on the market, and there is no doubt that the mechanism of the steam car is infinitely more simple and more easily understood and repaired by the man of moderate means, who is not an engineer, than the complicated mechanism of most petrol cars.

The boiler appears to be the principal trouble, but with ordinary care there should be no difficulty on this score, especially with the semi-flash boiler, the tubes of which are not liable to be burnt out, as are those in the ordinary tubular boiler. In some steam cars, in addition to the automatic water pump and hand pump, which latter should rarely or never be used, there is a small steam pump which can be actuated quite independently of the other two, and renders the liability of the boiler to run short of water practically impossible.

I have had very little trouble with my tyres, although the roads in my neighbourhood are made of sharp flints extracted from the chalk, and in some parts of Hertfordshire the roads are "terrors." I have recently had my car altered to burn petroleum, and I find that the cost of running is less than half what it was with petrol. It is not necessary to go to the heavy expense of a complete new burner for this apparatus, but an appliance can be fitted to the existing burner, and the petroleum being injected by a jet of steam prevents the accumulation of free carbon on the boiler pipes and also prevents the clogging of the burner and the various orifices through which the petroleum passes. In addition to that, a much greater heat can be generated in the boiler, the steam jet adding hydrogen to the hydro-carbon gases evolved from the petroleum.

I can run my car easily from fifteen to twenty miles an hour; a single charge of water will take me about twenty-five miles, and with a hose and the steam jet the tank can be refilled in about three minutes from any of the public drinking troughs, a river, or a pond. The petroleum tanks are sufficient for seventy to eighty miles, quite long enough for an ordinary day's run.

So far as "Mechanical Engineer's" letter is concerned, it is simply absurd; such a boiler as he describes is only fit for a locomotive or a steam wagon and would be perfectly impossible on an automobile. The only sentence in his long letter that I agree with is the last one, "A steam carriage of any (good) design, well and strongly made throughout, is the best on the road."—Yours truly,

Henry J. Rogers.

A WIRING QUERY.

To the Editor of *The Motor-Car Journal*.

Sir,—In the majority of descriptions of the wiring of two-cylinder engines I notice the current is made to run from the plus pole of the accumulator to one of the terminals of the double coil. On my Decauville car the wire runs from the plus pole direct to a bolt on the gear-box, while the negative wire is taken to the switch. Can you or any readers of the *Journal* inform me which is the most advantageous arrangement?—Yours truly,

W. A. W.

[It is usual when wiring an engine to run a wire from the plus or positive pole of the accumulator through a switch to the coil and earth the negative wire. This method has at times been reversed, but a wire from the positive pole to the coil generally proves the most advantageous.]

BELT TRANSMISSION.

To the Editor of *The Motor-Car Journal*.

Sir,—As several letters have appeared under this heading, some further remarks on the subject may not be out of place. The position is briefly this. There are a number of people who want a very cheap two-seated car (about £100), and who do not want to be bothered with gears and clutches. Now belt transmission as used in motor-cars some years ago was often very unsatisfactory, the usual trouble being continual slipping of the belts, or breaking of them altogether. These troubles were undoubtedly caused by want of proper protection of the belts, and also by using belts far to small to transmit the power. If these two details were attended to, there is no reason why a satisfactory small car should not be made and sold at a price within the reach of all. We must, however, look at the question from the manufacturers' point of view. Is the demand for such a car, as above described, sufficient to justify say a hundred or so of them being made? Most emphatically not. The people who ask for this type of car are, in most cases, people who have been brought up, so to speak, on

Digitized by Google

belt-driven cars, and have never been on a good gear-driven car, but have been frightened off them by exaggerated stories of faulty clutches and stripped gear wheels. Then there is another point. People who buy little cars want three speeds and a reverse. Now to work in three speeds and a reverse with belts is not so very easy and takes up a good deal of room, sun and planet gearing being generally used for the slow speed and the reverse (about the most wasteful type of gearing known). In my opinion the belt-driven car is dead, and any attempt to resurrect it will prove abortive.—Yours truly,

ASSAM.

RECKLESS DRIVING.

TO THE EDITOR OF *The Motor-Car Journal*.

SIR,—While driving my car the other day I had a very bad second or so. The roads were dusty, and I had just surmounted a hog-backed bridge to find the road swerve sharply to the right and ascend a slight hill. I had just time to tuck my car close in to the side of the road when a big car, coming down the hill towards me, attempted to take the curve at the bottom at something like twenty-five miles an hour. Needless to say it wheeled round nearly broadside-on, and by the greatest good luck —for me—just missed my car. I have not the slightest objection to this particular motorist immolating himself and his car, and there is much to be said for such a happy consummation; but I do think all fair-minded men will agree with me that he should do it decently by himself and refrain from making a holocaust of the occasion. The man was either mad or had not learnt the very elements of driving, and in either case the sport would be better without him. It is such folly as this that embitters road users and brings forward the opposition to motor-cars of which we hear so much.—Yours truly,

DUNCHURCH.

STEAM CARS.—"Mechanical Engineer" writes:—"In my letter in the *Journal* of September 24th, respecting a boiler for a steam car, I stated that the tubes should not be closer together at any point than 9-32 of an inch. This is a mistake, it should be 9-16 of an inch."

A WHEEL CAP was picked up in Wake Green Road, Birmingham, by the Heron Motor Co., of 89, John Bright St., Birmingham, who will be pleased to return it to the owner.

STORING PETROL WITHOUT A LICENCE.

Last week, at the Doncaster Borough Police Court, Messrs. W. E. Clark and Company, cycle agents, Station Road, were summoned for keeping petroleum on their premises without a licence. The Town Clerk (Mr. R. H. Tovey) appeared to prosecute on behalf of the Corporation, and Mr. G. W. Andrews defended. Defendants have a licence for their other premises. On Friday night Mr. Hanson, the inspector, went to the defendants' premises in Station Road and found 68 two-gallon tins of petrol spirit in a harness room on the premises. Mr. Clark said he thought that his licence for Benithorpe would cover the other premises. Witness went to Benithorpe and found 196 gallons. Defendants' licence covered 200 gallons. The value of the petrol on Station Road premises was £20. The defence was that the late inspector saw the premises and knew that the firm stored petrol there. They were under the impression that their licence covered both premises.

The Chairman (Mr. R. E. Clark) said that the magistrates considered there had been a gross violation of the Act of Parliament and that the defence advanced was by no means satisfactory. They attached no importance whatever to the evidence given respecting a man who was deceased, and which evidence could not be rebutted. They took into consideration the fact that this was the first prosecution of the kind in the borough, and fined defendants £5 and costs. They ordered the petrol to be forfeited.

THE "Badminton Magazine" for October contains a well-illustrated article on the Gordon Bennett race, which, although rather late, is somewhat interesting. It is written by Mr. H. Coutts, who seems to have taken advantage of the occasion for an interesting Continental tour as well as an opportunity to see an exciting event.

THE Gilburt Motor-car Company, Limited, has been registered with a capital of £10,000, to acquire the business of a motor-car manufacturer, carried on by Mr. E. A. Gilburt at 26a, Gopshall Street, Hoxton. The first directors are Councillor W. Watts, J.P. (chairman), J. Metcalfe, E. A. Gilburt, S. S. McNicol, A. R. E. Burton, and H. Horne.

IT will not be long now before fur coats, gloves and caps and similar sartorial adornments will be the rule, and anti-freezing mixtures the subject of discussion. Frozen and cracked water pipes and jackets will, unless care be taken, appear on the scene, and closed cars will become a favourite topic with motorists. As everything has its compensations, dust will disappear for a season, even although mud does take its place.

THE ABATEMENT OF THE DUST NUISANCE.

AT the German Automobile Congress recently held at Breslau a paper on "The Abatement of the Dust Nuisance" was read by Herr L. Van Westman, the inventor of Westrumite, from which we take the following:—

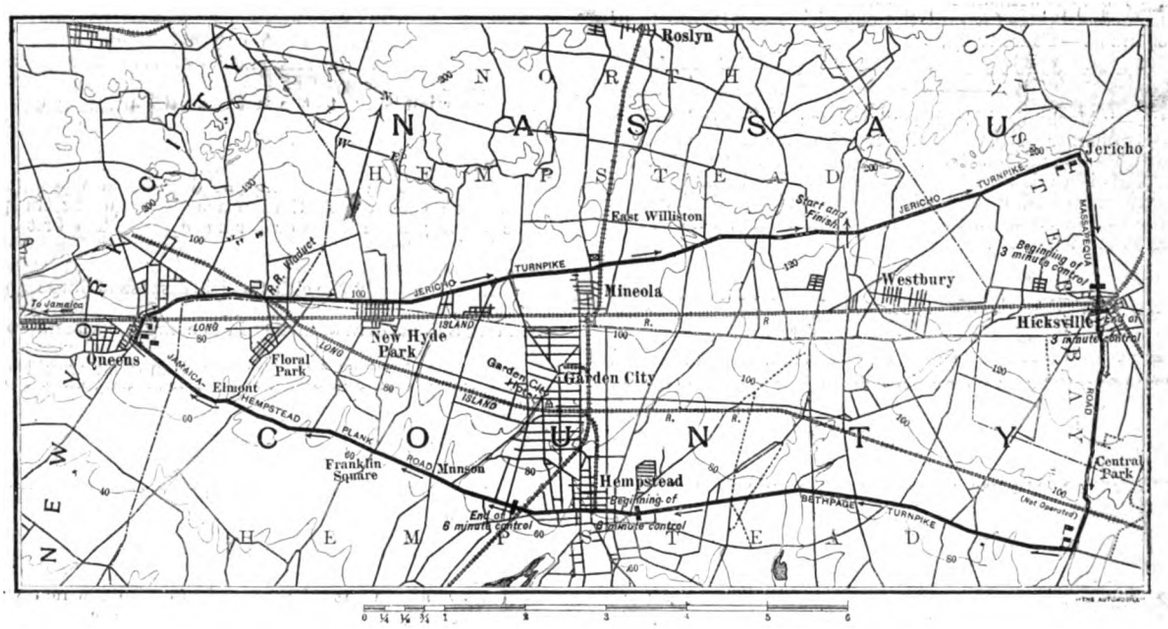
So much has been said and written on the dust problem that I shall confine myself to briefly discussing the harmful effects of road dust in a general manner. I believe that if it were possible to make streets entirely dustless the lives of millions of unfortunate consumptives might be saved. The material damage caused by dust to furniture, machinery, provisions, etc., is impossible to estimate.

Furthermore, real estate located on roads with much traffic depreciates in value in the course of time on account of the dust nuisance. The dust produced by the increasing traffic deprives many otherwise fine resorts of the advantage of a pure atmosphere. On the Riviera, for instance, it may be observed that trees and plants far into the gardens are entirely covered with a grey coat of dust. The pleasure drives, which were formerly so popular, have been almost entirely discontinued, because it is no pleasure to drive in a dense cloud of dust. As the dust is largely a portion of the street material and the latter is reduced by its removal, it follows that any process for binding the dust will tend to preserve the road surface. When this fact is once thoroughly understood by the authorities, we may hope to see the dust disappear from the streets within a definite time. Too much cannot be said against the practice of sprinkling streets with water, quite common everywhere, because water spraying loosens and destroys particularly macadamised streets, and produces a soft mud which may prove very dangerous to automobiles and horse riders, and the removal of which is expensive.

The widespread impression that dust is produced only through the wear of the surface layer of the street is entirely wrong. By far the greater portion is due to the fact that the pressure of traffic forces the heavy stones down into the road and allows the lighter material, sand pulverised to dust, to rise, from which result the holes in the street surface which are a source of expensive repairs. The abatement of the dust nuisance may practically be divided into two parts, viz.: (1) the suppression of dust on the surface; (2) binding the paving material either during construction or during repairs. The first operation consists in sprinkling the streets with suitable fluids. We need, however, not delude ourselves that the nuisance will be obviated by this means to any extent, because only the cities which dispose of large appropriations for street watering purposes are able to take up this problem, they spending a great deal of money in keeping the streets sprinkled, and by using suitable dust-binding fluids they might save sufficiently on wages that the introduction of the improved method would only occasion a very slight increase in the annual expense account. And yet, I am sorry to state, large cities which, after extended tests with a certain process expressed themselves entirely satisfied with the results, declared that this year they did not dispose of the necessary funds to introduce the process. The cause of this condition of affairs is that, as a rule, contracts for sprinkling are made with different establishments, and these contracts must be carried out. The funds available for sprinkling purposes are usually fairly well exhausted by these contracts, and it is therefore hardly possible to introduce any new processes while these contracts are in force.

I now arrive at the second question, which will be of much more interest to automobilists: How can country roads be rendered free from dust? Theoretically this end may be accomplished by the same means by which city streets are kept dustless, but practically these means are inapplicable, because the provincial authorities concerned can hardly be expected to make the necessary appropriations. The only way of accomplishing any beneficial results is to improve the methods of road construction. With the present method of building highways, which consists in compressing stone and sand with water by means of steam rollers, there can be no possibility of binding these materials together. Traffic will in time pulverise the sand and force it to the surface, with the result that the road is not only very dusty, but also in need of repairs. In America attempts have repeatedly been made to saturate the whole road with crude oil, but not much success has been attained, for the reason that it is very difficult to effect an intimate combination of the stones and the sand with oil. To overcome this difficulty, attempts have been made in England to heat oil and tar to a high temperature, and also the stones used in the construction of the road. Very good results have been obtained in this manner, but it is doubtful whether the process is of practical application because of the great cost and complication. Most of the experiments that have been made in this direction have always been on a small scale, the trial stretch being at the most 1,200 to 1,500 feet in length, and the engineers who conducted these experiments became convinced that the application of the processes on a large scale would be attended with many difficulties. Even leaving aside the question of cost, a process of this kind requires a complicated apparatus of heating tanks, etc., skilful employees, and an extended period of dry weather. As in practice it is impossible to foretell an extended rainless period, even in summer, little is to be expected from this method. This applies particularly in the case of a recently much-talked-of process for producing a compact elastic mass from a combination of tar and oil. If rain sets in during the time the work is in progress a thin mud is formed which requires weeks to dry, and during this period the road is practically impassable for traffic. This could be noticed in the Lenne-

Digitized by Google



strasse, at Dresden, at the time of the Building Construction Exhibition. On that occasion such a mud was produced that the city authorities found it necessary to have whole loads of sand dumped on the street to absorb the oily mud, and this sand had, of course, to be removed again. In addition, the streets became muddy every time it rained.

It will hardly be possible to use other materials than oil and tar for binding dust, for the simple reason that there are no other materials of equivalent effectiveness which are to be had as cheaply as crude oil and tar. All the experiments have shown that oil and tar have a very powerful binding effect, if it is only possible to completely saturate the sand and stones with them. The methods just described are, as stated, too bothersome, expensive and dependent on weather conditions, and require that streets treated must be closed to traffic for long periods. There is, however, a very simple method of securing the full benefit of the properties of tarry and oily substances, and avoiding their disadvantages, and this method consists in making these substances soluble in water, in which case they will be eagerly absorbed and strongly bind the street paving material into an elastically compact mass. The solutions may be spread on the roads by an ordinary sprinkling wagon, and if the work is done at night, the streets need not be closed to traffic. Care must, of course, be used that the oil or the tarry emulsion becomes insoluble after the evaporation of the water, because otherwise it would be dissolved and washed away by the next rain. The insolubility must, however, not be so complete that the substance is entirely incapable of absorbing water, but it must always retain the property of taking up enough rain water to bind any new-formed dust. This is the only means of preventing the production of mud, as the rain not absorbed will quickly run off, and the rest form an emulsion and bind the dust.

Practice has proved that roads thus treated dry much quicker after a rain than ordinary roads, and that there is no formation of mud, as in case of water-sprinkling or after a heavy rain. Now, if in the construction of a new road, either macadam or stone pavement, all the sand employed is saturated with this emulsion, it is bound together so effectively that it is impossible for the pressure of traffic to force it to the surface, and this already results in a considerable reduction of dust, as the production of dust by the wear of the upper surface, especially from automobile traffic, is very small. The development of dust through automobiles does not result from the wear of the stones contacted—the tyres being entirely too soft to produce any wear on stones—but results from the vacuum formed behind the contact of the wheel with the road surface, which sucks the sand from between the stones, no matter whether it is a macadam or stone-paved road. If, with the increasing automobile traffic, especially on the country roads, no efforts are made to provide an efficient binding material, it may be predicted with assurance that in future the life of the roads will be greatly reduced, because the extraction of the filling material, sand, from between the stones will naturally ruin a road much quicker than the surface wear from horse hoofs and iron tyres.

There is at present certainly no longer the least doubt regarding the rapid introduction of automobiles on a large scale, consequently the authorities entrusted with the care of the roads must get used to the idea that they have to count with motor-cars as a factor entitled to the use of the roads. The latter exist for traffic purposes, and in case the means of traffic are changed, the roads must be made to conform to the new requirements. Many rural and urban authorities have already begun to replace the otherwise very satisfactory macadam pavement with stone pavement, because it is more resistant to heavy traffic. But from the standpoint of the public this is very much to be deplored, because the stone pavement has not only the disadvantage that it disables horses in short order, but also causes much annoyance to everyone using the road or living near it, owing to the great noise produced. Besides, it is not exactly a pleasure to drive over such a pavement, whether with an automobile, bicycle, or horse-drawn vehicle, in case it is not absolutely uniform. This much to be desired uniformity will, however, hardly ever be secured on a country road. Automobilists are, therefore, much interested in the retention of macadamized roads; only they should be made dust-free and durable, because the dust and the many holes are the great disadvantages of a pavement which otherwise combines all desirable qualities, being almost noiseless, and much more uniform than stone pavement.

I hold that it is absolutely impossible to make a road absolutely dustless all at once for a period of years. I presume I may be allowed an opinion on this matter, as thousands of kilometres of roads have already been treated according to my method, and I have intently and persistently observed many roads. In case a road is saturated with oil from the beginning, the fine dust produced by wear will be absorbed by this oil. The case is somewhat different, however, with dust of earthy substances not in the pulverised condition, which are blown on to the road, ashes lost from wagons, etc. Even if the streets were covered with steel plates, as is now being tried in southern France, it would be impossible to make them entirely dustless. If the road surface is made too oily-

elastic, so that the oil or tarry substance will bind the dust on to the road into coarse grains, it will also stick to the shoes of pedestrians, rubber tyres, etc., and a lively agitation in opposition to roads thus treated might be expected.

It must not be forgotten that the authorities have to count with the public, who are only too much inclined to raise objections against such innovations. I have considerable experience in this line myself. While there have been no objections raised in America against the odour of crude oil, which is certainly very strong, and no complaints in over 100 cities where my method has been applied—the odour being naturally considerably reduced by the dilution of the oil—in Wiesbaden a number of persons pronounced the odour infernal, and stated that they would rather swallow the dust than have dustless roads and stand the smell. Lately, however, it has been possible to almost entirely obviate the odour.

As it has frequently been claimed that Westrumite has an injurious effect on the varnish of carriages, I would like to present an opinion from the noted chemist Dr. C. Bischoff, of Berlin. In connection with this opinion, I would remark that it is, of course, to be recommended to drive slowly over a road only recently treated. This is a matter of little moment, as the drying requires only a few hours, so that there can be no question of traffic delay. Fears have also been expressed that Westrumite might be harmful to rubber tyres. I have before me a letter from Herr Tischbein, of the Continental Caoutchouc and Gutta Percha Company, which is to the effect that these fears are unfounded. The Cyclist Touring Club in Holland has made extended experiments at its own expense in different cities, and sent a report to the Mayor of Nymegen

Digitized by Google

which was entirely favourable to the use of the emulsion. According to these several statements, it is shown that: (1) Westrumite binds the dust, and does not occasion too great expense as compared with water sprinkling; (2) no mud is formed during rain; (3) it does not injure the varnish of vehicles; (4) it has no injurious effect on rubber tyres, but, on the contrary, preserves them; (5) it has an appreciable saving and preserving effect on roads; (6) it kills weeds, but has no bad influence on trees, bushes, or other plants.

CLUBS AND ASSOCIATIONS.

YORKSHIRE.

ANNUAL SPEED TRIALS.

ON Saturday the second annual hill-climbing competition of the Yorkshire Automobile Club was held in Earl Fitzwilliam's park, at Wentworth Woodhouse, Rotherham. The course was exactly the same as that of the first trials—a measured half-mile along the drive in the lower part of the park. On the outward journey there was the benefit of a gentle fall in the ground. Therefore it was very necessary in arriving at the capabilities of a car that a run in the reverse direction should be made, the average of the two being taken, with flying start and finish prescribed. The fastest car in each class was adjudged the winner, and certificates will be issued in due course to the first and second in each event. Only members of the Yorkshire Automobile Club were eligible, and the cars were required to be privately-owned vehicles.

The results were as follows:—

Class I.—Cars with single cylinders up to and including 6-h.p.:—

	Outward. M. S.	Return. M. S.
A. Masser, Leeds, 6-h.p. De Dion	58 4-5	1.33 1-5
G. F. Whitworth, Bradford, 6-h.p. Prunel	1.13 3-5	1.58

Class II.—Single cylinder cars up to and including 10-h.p.:—

W. Booth, Bradford, 8-h.p. De Dion ...	1.0 4-5	1.16 1-5
— Bottomley, Leeds, 9-h.p. Renault ...	1.4	1.42 2-5
H. Martin, Huddersfield, 8-h.p. Renault	1.7 4-5	1.57 1-5

Class III.—Cars with double cylinders up to and including 12-h.p.:—

— Underwood, 10-h.p. Argyll	46 1-5	1.16 2-5
F. Churchill, Sheffield, 10-h.p. Hallamshire	1.2 1-5	1.17
W. Drew, Sheffield, 7½-h.p. Wolseley ...	1.2 2-5	1.48 4-5

Class IV.—Cars with any number of cylinders up to and including 16-h.p. (Mr. R. Winn's Cup):—

N. Baylis, Tattenhall, 14-h.p. Renault ...	39 3-5	58 4-5
Dr. J. Crossley Wright, Halifax, 15-h.p. Darracq	42 2-5	1.5 1-5
W. H. Jessop, Huddersfield, 15-h.p. Darracq	43 1-5	1.1 3-5
E. H. Watson, Leeds, 16-h.p. Argyll ...	44 2-5	1.2 1-5
W. W. Rycroft, Bradford, 15-h.p. Panhard	40 1-5	1.4 4-5
Bernard Bagshaw, Chapel Allerton, 15-h.p. Napier	44 3-5	1.21 2-5
F. Churchill, Sheffield, 14-h.p. Hallamshire	47 2-5	1.17
E. Faiers, Bradford, 12-h.p. Clement ...	47 2-5	1.18 4-5
— Mitchell, 15-h.p. Panhard	45 3-5	1.21 4-5
A. S. Fawcett, Dore, Sheffield, 15-h.p. Darracq	44 4-5	55
Dr. H. W. Williams, Holmfirth, 15-h.p. Darracq	44 3-5	57 2-5
Talbot-Hassell, 16-h.p. De Dietrich ...	50 3-5	1.36 1-5

Class 5.—Cars with any number of cylinders up to and including 30-h.p. (Mr. H. R. Kirk's trophy):—

A. Farnell, Bradford, 28-h.p. Daimler ...	35 2-5	46 1-5
S. Dixon, Bradford, 24-h.p. Fiat	37 1-5	55 2-5
R. S. Kirk, Headingley, 24-h.p. De Dietrich	38 1-5	60 2-5
W. Jackson, Bradford, 20-h.p. Brush ...	36 4-5	55
K. Neuman, Leeds, 30-h.p. R. and P. ...	48 3-5	———

Class 6.—Cars 30-h.p. and over:—

H. R. Kirk, Leeds, 60-h.p. Mercedes ...	30	31 2-5

Class 7.—Motor-Cycles up to and including 2¾-h.p.:—

G. H. Martin, Leeds, 2¾-h.p. Bat	55 3-5	———

Class 8.—Motor-Cycles 3-h.p. and over:—

— Parker, 3½-h.p. Griffon	40 2-5	54 3-5
Owen Brookes, 4½-h.p. De Dion	44 4-5	1.11

Among those present were Messrs. H. R. Kirk, Leeds, R. Winn, Leeds, H. A. Jones, Bradford, A. Moser, Leeds, A. Exley, Leeds, J. H. Pickford, Rotherham, W. N. Drew, Sheffield, Armitage, Wakefield, Dr. H. C. Barr, and Mr. A. W. Dougill, Hon. Sec.

AUTOMOBILE PROTECTION ASSOCIATION.

THE usual monthly meeting of the Council of the Automobile Mutual Protection Association was held at Cecil Chambers, Strand, W.C., on Friday of last week, when the Earl of Shrewsbury, President of the Society, took the chair. Seven firms were submitted for election and admitted to membership, whilst four members were added to the Council, viz.:—Messrs. Jesse Ellis (Maidstone), W. E. Rowcliffe (Manchester), A. Pereno (Farman Automobile Company), and W. R. McTaggart (Dublin).

It was decided to appoint a sub-committee for the commercial vehicle and heavy transport section of the society, and the following were appointed:—Messrs. Wm. Deighton (Yorkshire Wagon Company, Leeds), Jesse Ellis (Maidstone), Jno. H. Toulmin (T. Coulthard and Company, Preston), J. Donovan (Londonderry Works, Seaham Harbour), W. H. Maudslay (Maudslay Motor Company, Coventry), John T. Savage (King's Lynn), and Henry Spurrier, Jun. (Lancashire Steam Motor Company, Leyland).

The finance report showed available funds amounting to £2,044 5s. 10d. after providing for all liabilities.

There were present at the meeting (in addition to Lord Shrewsbury) Messrs. Albert Brown (Brown Brothers, Limited), Lieut.-Colonel Elton-Burroughs (Hewetson's, Limited), Charles Friswell, E. Lisle (Star Engineering Company), W. Lloyd McBride (Roadway Autocar Company), W. H. Maudslay (Coventry), A. Rawlinson (A. Darracq and Company), J. D. Siddeley (Siddeley Autocar Company), Henry Spurrier, Jun. (Lancashire Steam Motor Company), and D. M. Weigel (British Automobile Commercial Syndicate).

The new members admitted, being Nos. 167 to 173 on the register, were Messrs. A. Pereno (the Farman Automobile Company, Limited), E. Lamberjack (Société Franco-American), Albert Turner (Turner, Atherton and Company, Denton), F. Leslie Spencer (the N.A.G. Automobile Company of Great Britain and Ireland), John H. Toulmin (T. Coulthard and Company, Limited, Preston), and Messrs. A. Clement and A. R. Lucas (directors of Clement-Talbot, Ltd., London).

LINCOLNSHIRE.

ONCE more favoured with fine weather, though it rained hard up to mid-day, the last run of the Lincolnshire A.C. for the season, held on Saturday, was very successful. Saturday's meet was at Revesby, a very pretty spot in a lovely district between Boston and Horncastle,

The Yorkshire Club's Hill Climb—at the Start.

Photo by [*Owen Brookes.*

on the edge of Tennyson's country, the rendezvous being at the Red Lion Inn.

A meeting of the committee was held earlier in the afternoon, the members having previously lunched at the inn. The club members began to arrive at about 2.30, and there were several cars assembled in the open space before the house. Perhaps the one which attracted most attention was the new 18-h.p. Wolseley, belonging to Sir Hickman Bacon. The new 18-h.p. Siddeley driven down from town by Mr. J. D. Siddeley, and which has a new double hood, was much noticed. The 12-16-h.p. Clement of Mr. H. Marshall, Gainsborough, a member of the great engineering firm of Marshalls, also attracted attention. After a welcome tea, the party separated. Among those present at the meet were Sir H. B. Bacon, Bart., Gainsborough, and Sir H. Robinson, Dublin; Captain J. A. Cole, J.P., Roxholme (chairman) and Mr. E. Cragg, hon. sec., Billingborough; Mr. C. W. Pennell, Mr. W. R. Pennell, Lincoln; Mr. and Mrs. A. A. Padley, Market Rasen; Mr. W. and Mr. C. H. Gilbert, Mr. C. Nelson, Lincoln, Major Goddard, Lincoln; Major H. H. Williams, Woodhall Spa; Rev. and Mrs. Simpson, East Keal; Mr. and Mrs. Herbert Marshall, Mr. Anderson Pelham, Gainsborough; Mr. and Mrs. Tomlinson, Sleaford; Dr. de Beauvais, Ancaster; Mr. Lyttleton Rogers, Grantham; Mr. and Mrs. J. R. Richardson, Lincoln; Dr. Reckitt, Boston; Mr. W. S. Foster, Mr. J. Brown and Mr. R. M. Wright, Lincoln.

NORTHAMPTONSHIRE.

UNDER extremely pleasant weather conditions the members of the Northamptonshire Automobile Club had a most delightful outing on Thursday week, when the Hon. H. L. Brassey, one of the vice-presidents of the club, invited them over to Apethorpe Hall, his charming seat between Peterborough and Stamford. Between twenty and thirty cars

Digitized by Google

and motor-cycles started from the Club's headquarters—the Great Northern Hotel, Peterborough—shortly before 3 o'clock, and an extremely pretty ride along an undulating country through the villages of Thorpe, Castor, Wansford, and Nassington, was taken—Apethorpe being reached soon after half-past three. Here the motorists were welcomed by Mr. Brassey, and full permission was given them to roam about his beautiful grounds. Since Mr. Brassey acquired the estate from the Earl of Westmorland, extensive alterations and improvements have been in course of progress, and the Hall, a fine old mansion, from which lovely views are obtained across the park, is still in the hands of the workmen. Mr. Brassey is an ardent motorist, and two of his cars—a 15-h.p. Panhard and a 15-h.p. Charron—were on "parade." The others lined up on the east side of the hall to enable a photograph to be taken. Refreshments were provided for the motorists in the alcoves on the south side of the house. Successful arrangements were made for the outing by the club secretary—Mr. E. H. M. Wood. Amongst those present were the Hon. H. L. Brassey, 15-h.p. Panhard; Dr. and Mrs. Benson, 6½-h.p. Humberette; Mr. and Miss Adams, 12-h.p. Sunbeam; Mr. and Mrs. T. W. Mays and Miss Duckett, 12-h.p. Wolseley; Mr. and Mrs. R. Winfrey, 12-h.p. Beaufort; Mr. and Mrs. Cooke (Yaxley), 10-h.p. Locomobile; Mr. J. Rowe and Mr. J. Montgomery, 6½-h.p. Humberette; Mr. and Mrs. G. Linnell, 10-h.p. Wolseley; and the following on motor-cycles:—Mr. and Mrs. T. Rickman, 2¾-h.p. Royal Enfield with trailer; Mr. W. T. Southwell, 3½-h.p. Bat; Mr. O. Rowe and Mr. C. G. Hodgkinson, 3-h.p. Humber tri-car; Mr. A. Redhead, 3-h.p. Minerva; Mr. E. H. M. Wood (the Club Secretary), 2-h.p. Quadrant; Mr. T. Pearson, 3-h.p. Royal Enfield; Mr. T. Woodman, 2-h.p. Minerva; Mr. R. S. Parris, 2-h.p. Minerva; Mr. F. Redhead, 2-h.p. Quadrant; Mr. and Mrs. G. Guest, 3-h.p. Minerva tri-car, Mr. H. Ruff, 2-h.p. Minerva; and Mr. A. Redhead, 3-h.p. Minerva.

SHEFFIELD.

MEMBERS of the Sheffield and District Automobile Club, to the number of about 20, with their friends, met on Saturday afternoon on the village green at Castleton. The Fox House road rises at one point to an altitude of 800 feet, but the modern motor-car makes light of even the Derbyshire hills. The following mustered at the rendezvous:—Mr. J. Ellis, 6-h.p. M.M.C.; Mr. E. W. Hatfield, 6-h.p. Regal; Mr. J. F. Pickering, 10-h.p. Norfolk; Mr. T. G. Revill, 18-h.p. Darracq; Mr. James Barber, 7-h.p. Belsize; Mr. T. Bookless, 12-h.p. Gladiator; Mr. T. Chatterton, 6-h.p. De Dion; Mr. Hudson Lygo, 10-h.p. Cavendish; the hon. secretary, Mr. F. B. Cawood, was with Mr. Revill, and Messrs. F. W. Oates and W. James were in Mr. Ellis's car.

IRISH AUTOMOBILE CLUB.

THE annual hill climb, confined to members of the Irish Automobile Club, took place on Saturday, on a hill eight miles from Dublin, with a gradient of 1 in 11, as an average, while in some parts as much as 1 in 8. The distance of the allotted span from start to finish was seven-eighths of a mile. The contest was divided into four classes. Twelve competitors took part, and the fastest time returned was that made by Mr. W. G. D. Goff on his 20-h.p. four-cylinder Clement car, on which he recently drove H.R.H. the Duke of Connaught during the Army Manœuvres, and on which he returned to Waterford at the conclusion of the contest. Mr. F. V. Westby, on his 16-20 h.p. Argyll was successful in Class C, doing 3.22, the second fastest in the trials. Class A was won in a canter by Mrs. Mecredy, the only lady taking part in the competition, who drove her 6-h.p. De Dion. Messrs. Colman O'Connell and R. A. Eaton, club secretary, officiated as timekeepers. Mr. E. White, hon. secretary, and his committee deserve every credit for the manner in which they carried out the details.

Class A.—Touring cars, costing £200 or under.

				Min.	Sec.	
Mrs. Mecredy	6-h.p.	De Dion		4	37	1
J. H. Chancellor	6-h.p.	Siddeley		5	26	2
Colonel Thomas	7-h.p.	Swift		5	43	3
J. T. Cantwell	6-h.p.	Humberette		5	47	4

Class B.—Touring cars, costing £400 or under.

D. J. Mooney	10-12-h.p.	Argyll	6	10	
T. Talbot Power	10-h.p.	Wolseley	Retired.		
J. B. Dunlop, jun.	10-12-h.p.	Argyll	Not timed		

Class C.—Touring cars, costing £600 or under.

F. V. Westby	16-20-h.p.	Argyll	3	22	1
W. Sexton	10-12-h.p.	Peugeot	5	45	2
L. J. O. Higgins	10-12-h.p.	Gladiator	5	48	3

Class D.—Unlimited as to price.

W. G. D. Goff	20-h.p.	Clement	3	15	

WALES.

THE Welsh Automobile Club, one of the youngest of automobile organisations, has now a membership of over sixty, and intends to actively interest itself in motor boating.

POLICE TRAPS.

AT the bottom of the long hill at Cowfold, on the Brighton road, the police have a trap.

IN the village of Minskip, near Boroughbridge (Yorks), the police have a measured quarter of a mile on a road 60 feet wide.

CASES AGAINST MOTORISTS.

Place.	Summoned for	Fine.
Abergele	Driving recklessly	£10, etc.
Bridgwater	No rear light	2s. 6d.
Woking	Dangerous speed	Dismissed.
Horsham	Eleven cases of exceeding the legal limit	Fines ranging from £2 to £10 imposed.
Bradford	No identification mark at the rear	Dismissed on payment of costs, 5s. 6d.
Eastbourne	Driving to public danger	Dismissed.
Lewes	Driving motor-car without light.	40s., etc.
Croydon	(1) Driving dangerously; (2) failing to stop when called upon	(1) £5; (2) 40s.
Knaresborough	Driving dangerously	£5, etc.
Bristol	Driving dangerously	Dismissed.
Birmingham	Driving without rear light	10s., etc.
Kingston	Exceeding the ten mile limit in Richmond Park	40s., etc.
Dublin	Dangerous speed in city	£10, etc.
Kingston	Excessive speed	£2 10s.
City of London	Driving to common danger	5s.
Gloucester	Driving to common danger	£2, etc.
Ely	Dangerous driving	£3, etc.
Nottingham	Driving recklessly	40s., etc.
North London	(1) Furious driving; (2) without a licence; and (3) fraudulently using a licence issued to another person	(1) Dismissed; (2) Dismissed on payment of costs; (3) 40s. and costs.
Greenock	Failing to produce licence	£5, etc.
Altrincham	Driving furiously	£5, etc.
Dublin	(1) Not producing licence; (2) not stopping when requested to by a policeman	(1) 20s. 6d.; (2) £5.*
Carmarthen	Reckless driving	£1, etc.
Castleford	Furious driving	40s., etc.
Selby	Two miles above legal limit	10s., etc.
Lancaster	Driving unregistered car	5s., etc.
Folkestone	Driving to common danger	£2, etc.
Andover	Driving to common danger	£3, etc.
Chester	Beyond legal limit	10s., etc.
Guildford	Driving at dangerous speed	Dismissed.
York	Failing to stop motor-car when required	40s, etc.
Norman Cross	Exceeding legal limit	£5.*
Congleton	Speed dangerous to the public	£3.

* Notice of appeal given.

THE VANDERBILT CUP RACE.

THE following is the complete list of entries for the Vanderbilt Cup race, which is to take place on Long Island, U.S.A., to-day (Saturday):—

Entrant.	Car.	Driver.
UNITED STATES.		
Pope Motor-Car Co.	60-h.p. Pope-Toledo	A. C. Webb
"	24-h.p. Pope-Toledo	H. H. Lyttle
C. A. Duerr	40-h.p. Royal Tourist	J. Tracy
Packard Motor-Car Co.	30-h.p. Packard	C. Schmidt
Frank Crocker	75-h.p. Simplex	——
ITALY.		
W. Wallace	90-h.p. Fiat	W. Wallace
A. G. Vanderbilt	90-h.p. Fiat	P. Sartori
FRANCE.		
M. Clement, Paris	80-h.p. Clement-Bayard	A. Clement
W. G. Brokaw	60-h.p. Renault	M. G. Bernin
R. E. Jarrige	90-h.p. De Dietrich	L. Regan
Panhard and Levassor	90-h.p. Panhard	G. Heath
Panhard and Levassor	90-h.p. Panhard	Teste
Panhard and Levassor	90-h.p. Panhard	Tart
GERMANY.		
S. B. Stevens	60-h.p. Mercedes	S. B. Stevens
C. G. Dinsmore	60-h.p. Mercedes	——
Isadore Wormser	60-h.p. Mercedes	——
E. R. Thomas	60-h.p. Mercedes	E. E. Hawley
George Arents, jun.	60-h.p. Mercedes	Carl Mensel

Two White steam cars had been entered for the American team, but the cars could not be completed in time. The route map on another page shows the location and salient features of the course. The exact distance to be covered on each circuit is 30·24 miles. Nine circuits will be made, starting and finishing in the village of Westbury. The cars will be sent off at three-minute intervals, so that it is almost certain that one or more cars will finish their first lap before all the others have been started. This appears to promise complications, but elaborate precautions have been taken to prevent accidents.

Published Weekly by CORDINGLEY & CO., 39 & 40, Shoe Lane, London, E.C.

COMMENTS.

S.A.C.

AT a meeting of the General Council of the Scottish Automobile Club, held on Monday, a memorandum with regard to the lighting of vehicles in Scotland, prepared by the Secretary, was submitted. It was agreed to adopt the recommendations, and that communications should be opened with the County Councils Association with a view to inducing them to recommend the adoption of the suggested bye-law by the various county councils in the country. The memorandum is summarised on another page. On the suggestion of Sir R. J. Waldie Griffith, it was agreed to issue to the members of the club a cardboard placard for exhibition in motor-houses with regard to "Courtesies of the Road," summarised from and based on the club's recent circular with regard to inconsiderate driving and like matters.

◆ ◆ ◆

Oil on Roads.

ON another page we give the report of the Committee of the Western Section of the Scottish Club anent the oiling experiments they have recently undertaken by the permission of the Renfrewshire County Council. These have the value of being authoritative, and Mr. Robert Drummond, the road surveyor, was good enough to give every facility and assist in the preparation of the report. Apparently crude oil has given very great satisfaction from the point of view of economy, although the Westrumite is evidently cleaner to handle. Briefly summarised, the committee have come to the conclusion that for long stretches of road the cost of application is too great to bring it into general use, but in villages and residential districts the local authorities might do well to consider the laying of dust as being something that would be appreciated by the residents, at the same time enhancing the value of the property within their area; or, at least, if it does not enhance the value, would prevent the depreciation which, according to some agents, has followed the coming of the motor-car, so far as some main roads are concerned, for residential purposes.

◆ ◆ ◆

A New Ignition.

TWO of the cars—Mr. A. L. Guinness' 90-h.p. Darracq and Mr. C. Cordingley's 60-h.p. Mercedes—competing in the Blackpool speed trials this week was fitted with a new and interesting form of ignition which promises to become a serious rival to the magneto. Without drawings it is somewhat difficult to explain the system, but it may be briefly described as a cross between the jump spark of the high-tension ignition with coil and accumulators and the make and break of the magneto. An accumulator is used as usual, but in place of the ordinary induction coil a small cylindrical low-tension electro-magnet is employed and is attached direct to the plug, which, while of a special type, is provided with the same screw thread as the usual plug, so that it can be fitted without necessitating any alteration to the cylinder head. There is no high tension wire, the only wires being a short one from the battery to the magnet and another from the other terminal of the accumulator to the contact maker. The circuit includes two breaks, one of which is externally provided by the contact maker and is normally open, and the other, normally closed, is at the inner end of the plug. When contact is made externally, as the cam shaft of the engine rotates, current flows and energises the magnet, when by means of the consequent attraction, against a spring, of a soft iron armature attached to one of the contact pieces of the internal break, the latter is opened, and a spark—or rather a series of sparks, forming a continuous flame, due to the so-called extra-current of the induction circuit—is produced. The size and power of the spark, which has to be seen to be realised, is such that the complete charge in the cylinder is fired much quicker than usual, resulting in a more rapid explosion; while apart from this, one of the great advantages of the system is its ability to furnish a series of sparks at low as well as at high engine speeds. Altogether, we are much impressed with the new ignition, which we hope to illustrate and describe more fully in an early issue.

◆ ◆ ◆

£24 for One Offence.

A CASE which, on the face of it, appears to savour more of a persecution than a prosecution has just been heard at Woolwich. It was really one offence, but was divided into sections, with the result that a quartette of fines aggregating £24 have been imposed upon a working man in Woolwich Arsenal who happens to be fortunate or unfortunate enough to own a small motor-car. It appears he allowed his son to drive the automobile on a certain day recently, which of course he should not have done, seeing that the son had not got a licence. We should have thought that common sense would have dictated a summons against the son and there the matter to have ended; but instead of that, the father was summoned for (1) allowing another person to use his licence, and (2) with aiding and abetting that person to drive without a licence. The person who thus drove was then charged with driving without a licence, and, in various ways, the one offence was magnified until the sum of £24 was extracted from the two motorists for their indiscretion. Apparently this is the law, but then the law has been described as a "hass."

◆ ◆ ◆

In Ireland.

THE recent series of prosecutions of motorists which have taken place in Dublin led to the convening of a special meeting of the Irish Automobile Club to consider the position. The Right Hon. Sir Horace Plunkett presided, and amongst those present were Sir Ernest Cochrane, Bart., General Wolseley, Capt. Burnside, Dr. Joynt, and many other well-known Irish motorists. Mr. White, the Hon. Secretary of the Club, pointed out that the meeting was to consider recent judicial announcements of a very drastic character as to the speed of motorists generally, particularly in Dublin city. It appears that certain measurements have been made in Dublin, and that the slowest cab has been found to exceed over nine miles an hour, while other vehicles have gone even more rapidly through the streets, hence the feeling among motorists that they have been harshly dealt with is pretty general. At the end of a long and really excellent discussion, Sir Horace Plunkett proposed a resolution expressing the feeling that the action of automobilists as a body

Digitized by Google

had been much misrepresented, but as proceedings were pending in which these matters were still sub judice, the Club should content itself with re-affirming its readiness to co-operate with the police.

◆ ◆ ◆

On Tour.

THE two Oldsmobiles now on tour have been running to the time-table which was laid down for them at the commencement of the run. They had a terrible experience coming over Shap Fell; there was quite a gale blowing, accompanied by rain and hail, and the drivers never had a worse journey; in fact, the wind was blowing such a hurricane that they could not hear their engines working. They saw a lady blown right off her bicycle, and the driver of the small car went to her assistance. At Manchester a large crowd gathered on the morning of the 5th inst. to see them start off for Shrewsbury; from Shrewsbury they went to Cheltenham, from Cheltenham to Newcastle-under Lyme, and arrived last Saturday at Holyhead, when they completed 1,617 miles, being just over half the distance. They then took the boat for Dublin, which they reached in the early hours of Sunday morning, resting there till Monday morning, when they started on the Irish route, as follows:—Monday, Dublin to Belfast; Tuesday, Belfast to Dublin; Wednesday, Dublin to Waterford; Thursday, Waterford to Cork; making a total of 412 miles in Ireland. From Cork they crossed over to

The Two Oldsmobiles at Kendal.

Milford Haven, and are due to arrive there some time to-day (Saturday). From Milford Haven they go to Cardiff, from Cardiff to Gloucester, from Gloucester to Taunton, Taunton to Bodmin, Bodmin to Truro, and Truro to Exeter.

◆ ◆ ◆

Another Non-stop Run.

UNFORTUNATELY, indisposition prevented Mr. D. M. Weigel from carrying out his proposal to drive an 8-h.p. four-seated Talbot car without stopping over the routes of the A.C.G.B.I. trials in Herefordshire. He therefore started a car on Monday from the new works at Ladbrooke Grove to make journeys to various points on the outskirts of the Metropolis. The first day's trip was to Guildford, St. Albans, Crawley, Welwyn, and Maidenhead. On Tuesday, Tring and Welwyn were among the places visited, repeat journeys being made to each place. The engine was running continuously from the start, and up to eleven o'clock on Tuesday night 620 miles had been covered by the car.

◆ ◆ ◆

Motor-Car Imports and Exports.

THERE was again a falling off in the number of foreign motor-cars imported into this country during the past month, although the value of the imports showed a marked increase. The number of cars imported in September is returned at 386, of a value of £169,472. Parts were responsible for £33,863, bringing up the total for last month to £203,335, as against £160,279 in September, 1903. So far this year, that is to say, for the first nine months, the imports stand at £2,037,161, or approximately £380,000 more than in the same period of last year. Passing now to the exports of British automobile productions, the returns continue somewhat disappointing, only seventy-one vehicles being shipped last month, these with the "parts" being valued at £31,749, while for the nine months ending with September the exports are returned at £217,772, or about £17,000 below the total recorded for the corresponding nine months of last year.

◆ ◆ ◆

More Motor-Omnibus Services.

THE officials of the Great Western Railway Company in the Reading and Bristol districts have had a trial trip with two motor-omnibuses between Marlborough and Calne preparatory to the opening of a regular service. This will link up the two Wiltshire towns, which are only about thirteen miles apart, but at present are divided by a circuitous railway journey of something like forty miles. The cars will travel through a most interesting tract of country, and will serve not only the collegiate town of Marlborough and the famous bacon-curing centre at Calne, but also a succession of villages rich in historical and antiquarian interest. The journey will occupy about an hour, and there will be three sets of cars running each way daily at small fares. The vehicles are of 20-h.p., with two compartments, accommodating about twenty passengers.

◆ ◆ ◆

A Spin thro' Surrey on a Spyker.

THE other day we accepted a long-standing invitation to a run on one of the latest 20-h.p. Spyker cars, and, with Mr. A. E. Perman at the wheel, started off for what proved a most enjoyable cross country spin through Surrey. A somewhat unusual way out of London was chosen in order to test the hill-climbing qualities of the car on a little known but steep hill in Wimbledon Park. This being ascended without the least difficulty, we were soon on the main road to Kingston through Raynes Park, and as the open country was reached the throttle was opened a little more to give us an idea of the speed qualities of the vehicle. The main road through Kingston to the Angel at Ditton was given a wide berth, Mr. Perman having discovered a route to the last-named hostelry which, albeit somewhat tortuous and bumpy, avoids the watchful policemen of the ancient borough and their traps for motorists. Again on the high road and on the top speed, we flew along to Esher, past Sandown Park, where hippomobile races were in progress. Esher Common, and along the Fair Mile to Cobham, and then a sharp turn to the left to Church Cobham, where a brief halt was made to ascertain the way to Ockham, the finger-post being eventually discovered away up on the roof of a building, near the chimney-pots! The road is one which is apparently little known to motorists, or even cyclists, as we had it practically to ourselves, and in a few minutes found ourselves at the Hautboy at Ockham, where a stop was made for a welcome cup of tea.

◆ ◆ ◆

Home in the Dark.

THE return trip was made by a cross-country route, taking in Ripley, Send, Woking, Weybridge, Walton, Molesey, Hampton Court, and back again to town *via* Kingston and Wimbledon, and without a single falter on the part of the car or the engine. The latter is fed by an automatic carburettor, which renders it exceedingly flexible, enabling most of the running to be done on the top direct gear. The suspension of the vehicle, too, is all that can be desired in the way of rendering it easy riding, while a point which struck us favourably was the neat arrangement of the ignition and throttle levers. Altogether, the run convinced us that the modern Spyker car is an excellent specimen of automobile construction which reflects much credit on its designers and builders.

Refuse Collecting by Motor-Van.

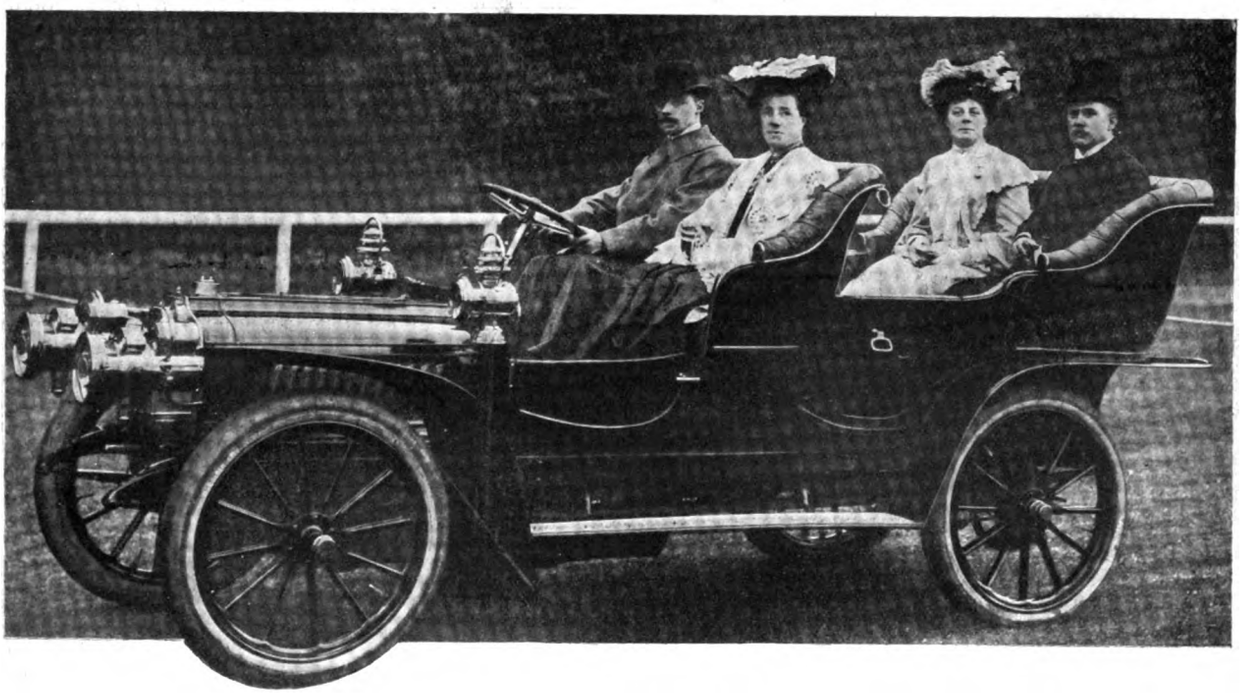
At a meeting of the Cardiff Health Committee the superintendent (Mr. Woosey) announced that, in accordance with the instructions of the committee, he was now ready to dispose of a number of horses which had been worked in the collection of refuse, they having become unnecessary since the introduction of the motor-wagons. Councillor James Robinson asked how many more motor-wagons would be required to enable them to dispense altogether with horses, and the superintendent expressed the opinion that six would be sufficient. The experience of this progressive Welsh town is evidently conclusive as to the value of the motor-van, while the decreased number of horses will be an advantage from the sanitary point of view.

◆ ◆ ◆

Technical Education.

Very significant is the development of technical education in London during the last few years, and the curriculum at most polytechnics and similar institutions will this season include classes in automobile work. Those at Battersea have already become famous, and at the Borough Polytechnic, too, developments in a similar direction are in progress. The Polytechnic School of Carriage and Motor Body Building commenced operations last week, and from the syllabus which Mr. Lewis J. Butler, the headmaster, has sent us, it would appear that a thoroughly practical course of work has been devised. Motor construction is also a subject among the practical trade classes at that old institution, and it is proof of the hold which the motor-car industry has obtained on the public mind that these technical schools are recognising the necessity of including the motor car as a subject of serious study.

◆ ◆ ◆



At Clerkenwell.

Lectures, drawing office work, laboratory work and workshop practice are included in the instruction which is now being provided at the Northampton Institute, Clerkenwell, E.C., in connection with Mr. C. E. Larard's classes for automobile work. These have been introduced in view of the rapidly growing importance of the industry, and the necessity of thorough technical instruction for those engaged therein. Those who are able to devote the necessary time to it are recommended to take the whole course, entry to which, however, will be confined to those actually engaged in the automobile engineering work. For the convenience of those who are unable to attend all sections of the work, separate fees are quoted for the different sections, and each application to enter any of these without taking the full course will be considered on its merits. In no case, however, will students be admitted to workshop practice without taking some other section of the full course. The number of students enrolled will be restricted to the available accommodation, and entries will close when this limit has been reached.

◆ ◆ ◆

A Practical Course.

The lectures, which commenced on the 13th inst., will be fifteen in number. The drawing office work will consist of a course of practical design. In the laboratory, students will receive practical instruction in the testing and running of oil and petrol motors. Two or three types of petrol motors will be fixed down in the engineering laboratories for testing, brakes and explosion recorders will be applied, and the power measured at different speeds. The various mechanical details of petrol motors will receive special attention, and the students will gain practical experience in the correct setting of the different parts. Instruction will be given in the workshop in the machining and fitting together of the various detailed parts of petrol motors to be used for motor-car work, and, if the time allows, the gearing and other structural work for the complete erection of motor-cycles or motor-cars will be fully dealt with; but the work actually done by individual students will depend upon their previous practical experience. The workshop accommodation is limited to twenty-five students, and preference will be given during enrolment to those who propose to take the complete course.

Mr. W. Foster, a well-known Member of the Nottingham Club, on his 24-h.p. Richard-Brasier Car.

◆ ◆ ◆

The L.C.C. and Cars.

At the meeting of the London County Council on Tuesday, Mr. Sanders moved that it be referred to the Parks and Open Spaces Committee to consider and report as to amending the bye-laws so as to prohibit the entrance into parks under the Council's control of motor-cars which emitted offensive odour. He said the emission of petrol vapour from these cars detracted from both the usefulness and healthfulness of the London parks. Mr. Beachcroft said the law was that every locomotive

Digitized by Google

using the highway should consume its own smoke, and he presumed it should consume its own smell as well. Mr. D. S. Waterlow did not think the Council should treat the motion too seriously. No doubt a badly smelling motor-car was extremely objectionable, but the majority did not smell offensively. The motion was rejected by a large majority, which was not a matter of wonderment, seeing the large revenue which the Council draws from automobilists.

◆ ◆ ◆

Cars in London

THE registration of automobiles still continues, and in the three months ending September 24th no less than 567 motor cars and 305 motor cycles were registered by the London County Council, so that in the first nine months of the present year no fewer than 4,471 motor-cars, and 3,078 motor-cycles were registered within the London area, a total of over 7,500 automobiles, which proves how popular the mechanical vehicle has become within a remarkably short space of time. As many as 10,902 licences to drive motor vehicles have been issued, and 287 general identification marks have been issued to dealers during the same nine months. Facts such as these should make the local authorities careful in seeking to impose restrictions upon a body of people so rapidly growing both in influence and in numbers.

◆ ◆ ◆

Mrs. Charles Jarrott in an 8-h.p. De Dion-Bouton Landaulet.

The Blackpool Meet.

ON Wednesday morning entries of more than fifty cars were received for the Blackpool meet, and the names of competitors to be added to the list, on page 684, include Miss Hampson, Messrs. H. Sturmey, Keele, G. Higginbotham, Elsworth, Cook, Coddington, Higgins, Hammond, Whittaker, Lord, Metcalf, Howell, Garner, Womersley, Goddard, Lumb, Whatcoat, Anderson, Rignold, Austin, Marston, Kennedy, Richmond, Birtwistle, Guinness, Winton Carriage Co., the Fiat Co., and the London Motor Garage Co.

◆ ◆ ◆

International Cup for Motor-Boats.

MR. BASIL JOY sends us the rules for the British International Cup for motor-boats for 1905, as amended by the International Commission. An important alteration has been made in Rule 6, which now provides that the start shall be a flying one, all competitors starting together by a signal, thus preventing any possibility of such a mishap as occurred this year at Ryde, when Napier Minor was robbed of her victory. Rule 4 lengthens the course from between six and twelve knots to between thirty and thirty-five knots, thus giving a chance of a better type of boat being evolved. Another important alteration in connection with the course is that it must now be arranged so as to avoid all angles of less than 120 degrees, the length of each round to be not less than five nautical miles. Other minor alterations have been made, but the foregoing are the more important in connection with an event that is likely to become of increasing interest and importance as time goes on.

◆ ◆ ◆

In the West Riding.

IN the West Riding of Yorkshire several of the county magistrates have been wagging their heads together because, it appears, some of them have observed motor-cars going at quite rapid rates of speed along country lanes which have been regarded for generations as sacred to the lumbering market van or the slow moving agricultural wagon. Some of them have become quite alarmed at the rapidity of the motor-car, and are beginning to worry the District Councils to see whether these modern engines cannot be stopped altogether. After much serious discussion, they have gravely adopted a resolution advising the police throughout the West Riding to place their various stations in telephonic communication one with another. We can imagine with what relief these worthy wiseacres, having seriously discussed the problem for several hours, rose to go to their luncheon. After adopting such a course, doubtless they will expect that motorists will either go at a snail's pace or keep out of the West Riding altogether. We shall see.

◆ ◆ ◆

Cotton Motor Tyres.

THE first meeting of Hyatt's, Limited, was held on Tuesday, when it was stated that the company was formed to work an American machine, and had taken a mill in Lancashire, which was being rapidly equipped. The products of the company were machinery belting made from cotton on the principle of cotton wicks for lamps. This has been so far developed that a machine has been constructed which will produce a motor-car tyre continuous and endless, and of the form and shape of the wheels, to which it would be fitted without any labour further than what was necessary to drive the machinery, and would have a bursting strain greater, it is claimed, than any fibre which had yet been put into the motor tyre. It was estimated that the bursting strain of the tyre would be 6,000 lb. per square inch, and that one tyre could be made in the machine in thirty minutes.

◆ ◆ ◆

Progress in Ceylon.

MOTOR-CARS are advancing rapidly in Ceylon, and their popularity has been growing to such an extent that an automobile association for the island has been proposed. Mr. Harold North, of Bellongalla Estate, Kadungannawa, suggested the idea and is trying to carry it through. He has already received the names of fifty likely members. The notion of a motor mail service from Colombo to Puttalam is being advocated in many quarters. This and the formation of an automobile association indicate great advance.

◆ ◆ ◆

Local Antipathy.

LOCAL authorities continue to discuss the speed of motor-cars, and at the Dunfermline District Committee Lord Elgin has reported that the surveyor has prepared a list of dangerous hills, turnings and cross roads in the West Fife district, at which danger boards are to be erected at a cost of £1 per piece. The Yorkshire County Council has informed the Scarborough Rural District Council that at a dozen places within its area similar posts will be erected, and elsewhere the question of the erection of sign boards has cropped up. Some, however, have gone even further, and the Parish Council of Clayton, which is somewhere in Sussex, has passed a resolution urging the Roads and Bridges Committee of the County Council to see whether motor-cars cannot be altogether prohibited from certain of its roads.

Digitized by Google

LIGHTS AFTER DARK.

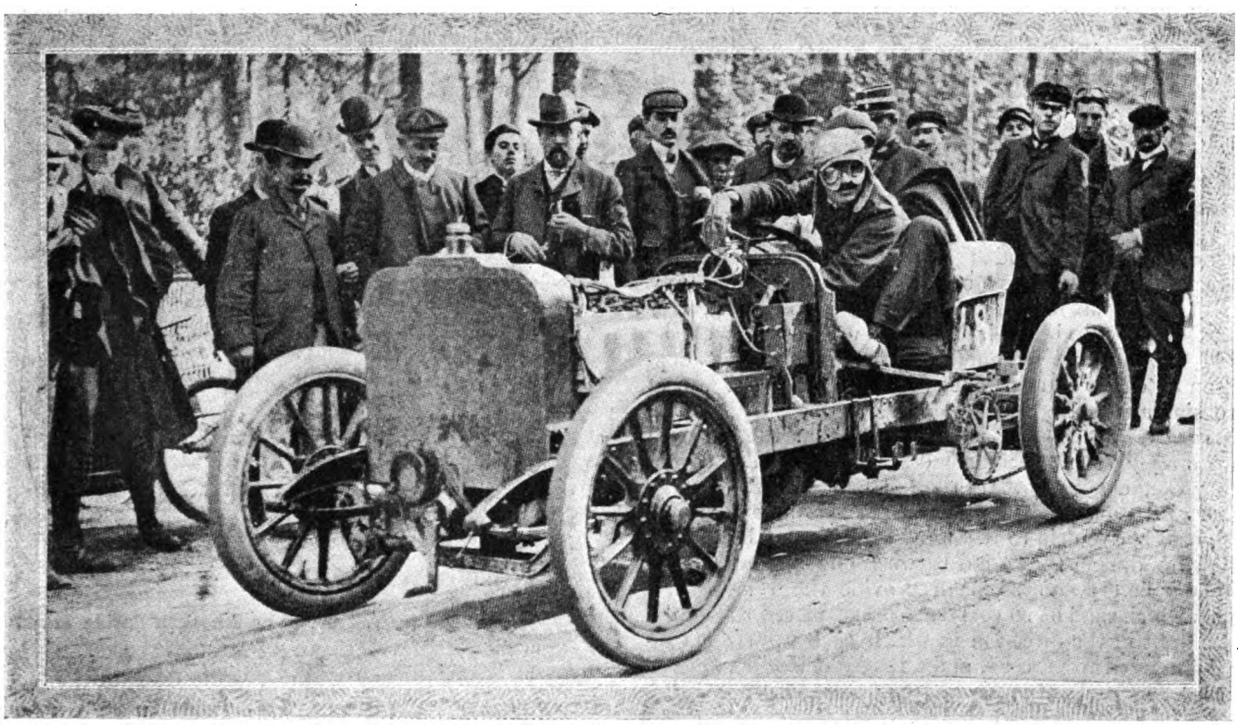
THE POSITION IN SCOTLAND.

MR. R. J. Smith, the Secretary of the Scottish Automobile Club, has drawn up the following memorandum with regard to the lighting of vehicles after dark in Scotland. By section 50 of the Burgh Police (Scotland) Act, 1903, which came into force on May 15th last, it is provided:—"That every vehicle drawn by animal power and driven upon any street during the period between one hour after sunset and one hour before sunrise shall carry a lamp or lamps exhibiting a white light in the direction in which the vehicle is proceeding, provided that where one lamp only is carried it shall be, or where more than one lamp is so carried, one shall be attached to the extreme off or right side of the vehicle: and that any carriage used for the purpose of carrying timber or any other load which projects more than six feet beyond the rear shall in addition exhibit a red light visible to the rear, showing the extent to which the load projects behind the vehicle."

This provision is applicable to every burgh in Scotland with the exception of Edinburgh, Glasgow, Aberdeen, Dundee and Greenock, by whom its adoption is permissive. In none of these cases has this section been adopted. In Edinburgh, every carriage or van requires to carry lighted lamps on each side between half-an-hour after sunset and half-an-hour before sunrise. In Glasgow there are no provisions for the lighting of horse drawn vehicles after dark with the exception of the regulations relating to hackney and stage carriages, which are required to keep lamps clean and lighted between sunset and sunrise except from 1st May to 15th August. In Aberdeen, hackney carriages only are required to carry lights, the months of May, June and July being excluded. In Dundee all carriages and vehicles proceeding at a greater than walking pace are required to carry lights. In Greenock there are no regulations whatever.

In terms of the Local Government Board (Scotland) Act, 1889, and of Section 104 of the Roads and Bridges (Scotland) Act, 1878, County Councils may from time to time, it is assumed, make, with respect to the highways within their jurisdiction, bye-laws requiring vehicles to carry lights at night. In twenty-seven counties such bye-laws are in force and in six there are none.

In the majority of cases the following are the terms of the principal bye-law:—A. During the period between one hour after sunset and one hour before sunrise every person driving or being in charge of a vehicle placed upon springs shall carry and exhibit, attached to each side of the said vehicle, a lighted lamp so constructed and placed as to exhibit a light in the direction in which the vehicle is proceeding.



This applies to the following counties:—Aberdeen, Argyll, Ayr, Banff, Berwick, Clackmannan, Dumfries, Dumbarton, Fife, Forfar, Kincardine, Kinross, Kirkcudbright, Lanark, Linlithgow, Orkney, Peebles, Perth, Roxburgh, Selkirk, Stirling and Wigtown.

In several instances a similar bye-law, somewhat wider in its terms, is in existence:—B. During the period between one hour after sunset and one hour before sunrise every person driving or in charge of any vehicle drawn by animal power which is going faster than a walking pace, shall carry and exhibit attached to each side of said vehicle a lighted lamp so constructed and placed as to exhibit a light in the direction in which the vehicle is proceeding. This is in effect applicable to the counties of Bute, Fife, Haddington, Kinross and Midlothian.

The following supplementary bye-law is commonly adopted:—C. During said period every person driving or in charge of a cart or carts loaded with wood of any description, or iron bars, shall carry and exhibit a lighted lamp attached in such a way as to show the furthest out projection on each side of the cart and so constructed and placed as to exhibit two efficient clear lights in the direction in which the cart is proceeding. This is adopted by the counties of Ayr, Berwick, Dumfries, Kirkcudbright, Orkney, Peebles, Perth and Roxburgh.

Slow traffic is provided for by the following clause:—D. Vehicles not on springs shall proceed only at a walking pace. This is applicable to the counties of Ayr, Banff, Berwick, Dumfries, Dumbarton, Kirkcudbright, Lanark, Orkney, Peebles, Perth, Roxburgh and Shetland.

E. During the summer months, May, June and July, exiist ing bye-laws are suspended in the counties of Aberdeen, Banff,

The Dourdan Speed Trials.—Dufaux on the Dufaux Eight-cylinder Racer.

Digitized by Google

Dumfries, Shetland, and Wigtown, in the county of Berwick during the period from 20th May to 20th July, and in the county of Orkney from 15th April to 15th August, while in the county of Kirkcudbright as regards May, June and July the words "one hour after sunset and one hour before sunrise" read "two hours" in each case.

F. No regulations are in force in the following counties:—Caithness, Elgin, Inverness, Nairn, Ross and Cromarty, and Sutherland.

G. The county of Renfrew has a special bye-law requiring lights, or one light on the off side, to be carried by all two-wheeled vehicles on springs, and by every vehicle having four wheels.

H. The county of Midlothian furnishes the only instance of a rear light being required. The regulation is as follows:—"During the period between one hour after sunset and one hour before sunrise every person driving or being in charge of any wagon, cart, or other carriage loaded with timber, trees, or other material, projecting five feet or more in rear of such wagon, cart, or carriage, shall carry and exhibit a lighted lamp attached at the back in such a way as to show the furthest out point in such projection."

The County Councils Association have remitted to a sub-committee to prepare a model set of bye-laws, which, if approved by the Association, will be recommended for general adoption, and they have expressed a desire to receive the report of the Council of the Scottish Automobile Club, and willingness to consider their views before they frame their recommendations.

With respect to burghs no action appears called for. It has been made obligatory by the Statute that lights be carried, and while no rear lights are provided for, the necessity for these within the limits of burghs is not great, and to obtain any amendment to the recent law would be in the meantime exceedingly difficult. It would be desirable, however, to approach the authorities of Glasgow and Greenock with a view to their adoption of Section 50 of the Burgh Police (Scotland) Act, 1903, or of a bye-law to similar effect.

In the case of counties it is suggested that the General Council should approve and recommend for the general adoption of the County Councils in Scotland the following set of bye-laws:—"(1) Every person who shall cause or permit any carriage, cart, wagon, or other vehicle to be driven or ridden or be on any street or highway during the period between one hour after sunset and one hour before sunrise, shall provide the same with a lamp or lamps which shall be so constructed and placed as to exhibit a white light in the direction in which such vehicle is proceeding or is intended to proceed, and a red light behind, and so lighted and kept lighted as to afford adequate means of signalling the approach or position of the carriage, cart, wagon, or other vehicle; providing that, where one light is shown in each direction, the lamp exhibiting it shall be attached to the extreme off or right side of the carriage, cart, wagon, or other vehicle. In case of the load carried by said vehicle projecting beyond the sides thereof, the light or lights shall be so placed as to show the furthest out projecting.

"(2) Such person shall also, if the vehicle is used for the purpose of carrying timber or any load projecting more than six feet to the rear, provide an additional lamp or lamps, so constructed and capable of being so attached to the end of the projecting load as when lighted to show to the rear a red light, visible within a reasonable distance to persons overtaking the vehicle, and to show the extent to which such timber or other load projects behind the vehicle."

"(3) Every person driving or being in charge of such vehicle as aforesaid in any street or highway during such period as aforesaid shall keep such lamp or lamps properly trimmed, lighted and attached."

The question of lighting flocks of sheep, droves of cattle and the like is not without importance, but it would appear to be meantime premature to deal with it.

A MOTOR mail service is about to be inaugurated between Tonneins and Caneon (Lot et Garonne), France.

CONTINENTAL NOTES.

An American Invasion.

One of the features of the French motor industry at the present time is the great attention that is being given to America, which is proving an important market for French automobiles. Quite a number of manufacturers are represented at the St. Louis Exhibition, while the race meeting during the next few months, of which a number are promised, are likely to witness the appearance of several well-known French *chauffeurs*. Messrs. Gabriel, Teste, Tart, Heath, and Clement, jun., recently went over to the United States, an intrepid group which is now to be joined by Thery and Caillois, who sailed from Havre on the "Lorraine" last week. The former has with him the Richard-Brasier on which he won the 1904 Gordon Bennett race, while the latter will drive the light car which won the Chateau-Thierry and Ventoux hill climbs in 1903.

◆ ◆ ◆

Public Services in Germany.

A company has just been formed at Schonach, Germany, to organise a public service of motor vehicles between that town and Torberg. A service is also to be started between Halle and Dolau, while one is projected between Santomischel and Schroda.

◆ ◆ ◆

Taking a Corner on an American Racing Track.

◆ ◆ ◆

The French Military Motor Vehicle Competition.

Only three vehicles out of the seven entered presented themselves to take part in the military motor-wagon contest organised under the auspices of the French Minister of War, which was to have started on Monday of last week. These were a Cottereau vehicle, one by Mathian Frères, and one by M. Latil. After going through the weighing formalities, they were sent off on their first day's journey by the authorities, and later on two Aries wagons arrived. The Commission then held a meeting, and after a long discussion decided to postpone the competition *sine die*, they considering that the vehicles did not conform to the requirements specified in the conditions. The decision came as a surprise to the competitors, who, naturally, were anything but pleased with the announcement. Messrs. Cottereau, for instance, had gone to great trouble and expense in building a special vehicle, having kept their men working almost night and day to get the car finished in time.

◆ ◆ ◆

1905 Models.

It is reported that Messrs. Renault Freres are at work on a new model, fitted with a 20-28-h.p. motor, which will make its appearance at the *Salon* in December. This car, except for the size of the motor, and that it is fitted with a pressed steel frame, will be similar to the present 14-h.p. Renault, and will have the new type of radiator, which has proved very successful in practice. As already mentioned, the 1905 models of

Digitized by Google

Mercedes will be confined to two sizes, 28-32-h.p. and 35-40-h.p. These will be on very similar lines to this year's cars, but will be made in various lengths of *chassis*—7 ft. 3 in. for tonneaux, 8 ft. for side-entrance bodies, and 8 ft. 6 in. for coupés and six-seated bodies. It is also reported that a 8-14-h.p. three cylinder Mercedes is to be introduced. It will probably be almost a year before it is ready, so that to all intents and purposes it may be regarded as a 1906 rather than a 1905 model.

◆ ◆ ◆

The French Carburettor Competition.

The results of the Carburettor Competition held during the past season by the French Automobile Club have just been announced. In Class A, for carburettors for a special motor, no award is made. In class B, for carburettors using ordinary paraffin, Madame Vve. Longuemare and Messrs. Gautreau both receive silver medals. Class C, for carburettors for any motor using any type of fuel, Madame Vve. Longuemare, gold medal; J. Saint-Denis, silver gilt medal; Messrs. Hannon and Co. (Constantini carburettor), Messrs. Michaux and Co. (Gallia carburettor), and F. Chalon (Automatisme carburettor), all silver medals.

◆ ◆ ◆

Motor Traffic Regulations in Italy.

The Special Commission, consisting of various Senators and Deputies, of the Mayor of Rome, several officials, and some experienced automobilists, which was appointed by the Italian Minister of Public Works to inquire into the question of regulating the speed of motor vehicles, has presented a report, which will soon be laid before the Cabinet. The main recommendations of the Commission are two. The first, which applies to all vehicles, prescribes that they should always keep to the right-hand side of the road; but, in order not to break with ancient customs, mayors of towns of more than twenty thousand inhabitants may issue orders permitting carriages and motors to drive on the left. The second recommendation, which applies specially to motor-cars, will, if adopted by the Cabinet, reduce their speed in towns and villages from fifteen to twelve kilometres an hour, but will abolish the speed limit in the open country altogether. It is further proposed that every automobile, in addition to the plate with the name of its place of origin and its number, which is fixed behind, shall also have one in front.

◆ ◆ ◆

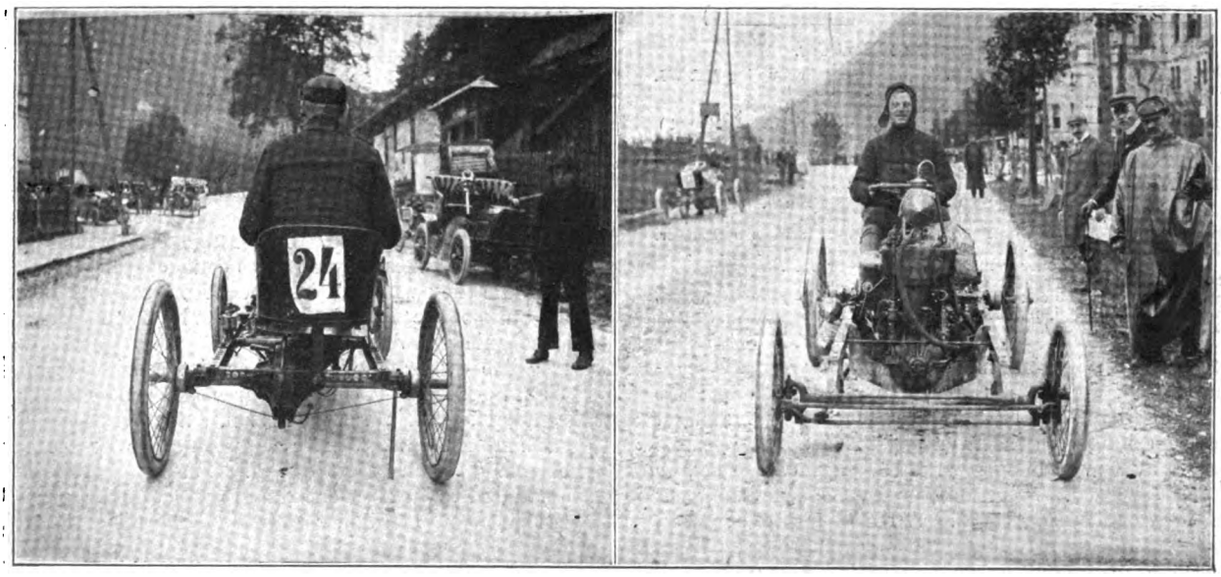
One-third Litre Motor-Cycle Criterium.

SIXTY-THREE entries in all were received for the "Criterium du Tiers de Litre" organised by the "Auto." The weighing and cylinder measuring took place on Tuesday last week and the racing commenced on Wednesday, when the first two "series" of ten competitors each took their turn—one set in the morning the other in the afternoon—on the Parc des Princes track, in Paris, over a distance of 100 kilometres. The four other series followed on Thursday and Friday, two each day. The final should have taken place on Saturday, but, owing to rain, it was postponed until Sunday. The final includes the first two machines in each of the series. In each case it is the machines which are qualified to take part, it being permissible to change the riders. An extra prize in the form of a challenge cup was offered to constructors who elect to run machines in sets of three, as designated beforehand. The best performances of these groups determine the winner of this trophy for regularity of running and reliability. The following twelve competitors qualified for the final:—

Rider.	Machine.	Motor.	Bore and stroke mm.	Transmission.
Anzani ...	Alcyon ...	Buchet ...	76 by 73 ...	Belt
Bac ...	Magali ...	Deckert ...	76 by 73 ...	Chain
Lanfranchi ...	Peugeot ...	Peugeot ...	70 by 86 ...	Belt
Champoiseau	Griffon ...	Z.L. ...	72 by 80 ...	„
Griet ...	Alcyon ...	Buchet ...	76 by 73 ...	„
Georgis ...	Buchet ...	Buchet ...	76 by 73 ...	„
Collomb ...	Magali ...	Deckert ...	76 by 73 ...	Chain
Cissac ...	Peugeot ...	Peugeot ...	70 by 86 ...	Belt
Hibon ...	Lurquin-Coudert	L. and C. ...	74 by 76 ...	„
Meline ...	Stimula ...	Stimula ...	75 by 65 ...	„
Champoiseau	Griffon ...	Z.L. ...	72 by 80 ...	„
Cissac ...	Peugeot ...	Peugeot ...	70 by 86 ...	„

◆ ◆ ◆

The Result of the Final.



All the twelve riders who competed in the final on Sunday succeeded in completing the 100 kilometres. The event proved a victory for Anzani, who on an Alcyon machine with Buchet 76 by 73 mm. engine completed the distance in 1 hr. 18 min. 37 sec., Giorgis on a Buchet being second in 1 hr. 19 min. 58 sec., and Melin on a Stimula third in 1 hr. 24 min. 48 sec.

◆ ◆ ◆

The Gordon Bennett Race.

It is reported that Messrs. Turcat Mery and Company, of Marseilles, are already at work on their racer for the eliminating trials for the French team for the 1905 Gordon Bennett race. It will, it is stated, be of about 100-h.p., and is expected not to weigh more than 800 kilogrammes complete.

MESSRS. SALSBURY AND SON, LIMITED, have just introduced a simple arrangement, controlled from the dashboard, by means of which the light on their acetylene head lamps may be raised or lowered at will.

THE DENT BELT RACE CONE TRANSMISSION SYSTEM.

WHEN the question of transmission first occupied the attention of car designers, they turned instinctively to the belt as affording the most suitable medium to bridge the gap between the ever-changing relative positions of the motor and road wheels, and although many cars were thus constructed, and indeed are still on the road, the difficulties of having so many pulleys and belts, the annoyance of stoppages for adjustment, the slipping, wear of belts, and so on, soon made themselves apparent, and this otherwise ideal drive was discarded. Messrs. Dent and Son, of Tamworth, however, claim to have entirely overcome these drawbacks with their belt race cone system, and, moreover, dispense with side chains, live axles, cardans, and bevel drives, as well as speed gear-boxes, by simply using two specially constructed light weight cones and a single belt, the latter being controlled by a combined power-driven belt striker and sliding ball-bearing jockey. The belt is moved either way into the various speeds by a pedal which actuates ball-bearing roller forks by worm-threaded rods driven by either of the miniature clutches. The makers state that the tensioning spring-connected lever requires very little pressure to give a gear-like grip, and a

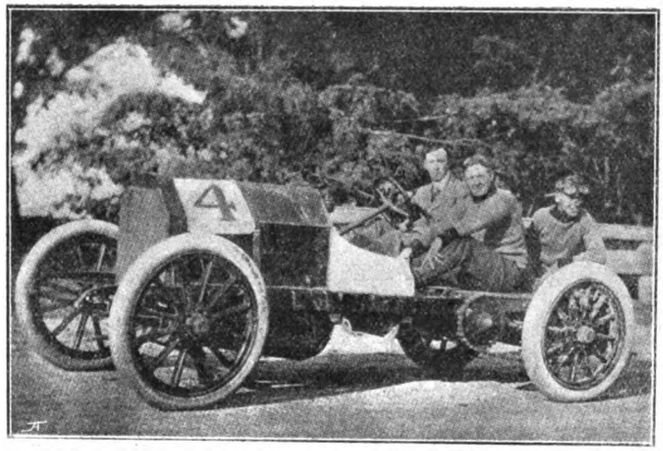
nice adjustment is thereby obtained. The cones are made principally of aluminium, weighing from ten to twenty pounds; the back one is mounted on the balance-gear shaft over a cranked axle, its pinions meshing with the internally-toothed brake drums. The front cone may serve the purpose of the engine flywheel, or a clutch can be interposed, three, four, or five speeds being the usual number provided by the cones. A recent improvement in the system consists in the introduction of a power friction-driven belt striker instead of a hand wheel. Two miniature clutches now automatically move the belt on depressing the pedal, the four points of the attachment being coupled by small cycle chain. The striker will be best understood by reference to the illustrations. The pedal is depressed and one or other of the clutches immediately revolves the screwed rods, the indicator showing the speed obtained. By means of this pedal the car can be slowed or accelerated in traffic to a nicety. At the same time, as the belt is being carried over by the ball-bearing roller forks, the jockey follows it. The latter is connected by a tension spring on the end of its sliding rod to the tension lever, and "take up" is thus automatically accomplished when setting the lever in the desired notch. The belt is of such a construction that a gear-like grip is obtained with very little tension, and on ordinary roads it will drive slack. The splice is nearly invisible, and it can be quickly shortened; the latter, however, is never necessary on the road, by reason of the margin allowed by the jockey and the non-stretching qualities of the belt. We have not had an opportunity of trying a car fitted with the transmission ourselves, but Messrs. Dent inform us that they have experimented with a heavy solid-tyred car over a hilly route in Wales, and that with eight passengers the cost of petrol and paraffin for the single-cylinder engine works out at 5d. for thirty miles. They also inform us that no shortening of the belt was required, and that the speed-changing and starting is notable for the easy wave-like motion imparted to the car. Extreme simplicity, ease of operation, small upkeep, silence, flexibility, and efficiency, and correctness are among the claims made for the system.

THE VALUE OF THE MOTOR-CAR.

MR. T. L. JOHNSON, the Mayor of Cleveland, U.S.A., is one the recent converts to motoring, and in an American contemporary has given expression to his views on the modern means of travel. "In the beginning," says Mr. Johnson, "I looked upon the motor-car as a toy, but my admiration for this means of locomotion grew with the development of the art. It is now a part of my daily life, and I have given up horses entirely, not only using the motor-car for business, but for recreation as well. High speed does not appeal to me, and I think scorching, both in the country and city, is to be frowned upon, for it annoys a great many people who ought to be friendly to the motor-car.

"It is my belief, however, that this evil will disappear, and harsh legislation against it will be found unnecessary, as was the case with cycling.



"So far the development of automobilism has been largely along the line of the touring car, but a greater field of utility will be found in commercial work; and a still broader one when its development reaches a degree of perfection and economy of construction that will permit its use by farmers, for a simple and low-priced wagon will be greatly desired by the rural community. This will overcome the prejudice of farmers and gain their influence for better roads. The side-door touring car is taking the place of the one with the awkward rear entrance. The need for high-grade carriage construction is now being so rapidly supplied that all further excuse or necessity for closed vehicles, drawn by horses, will disappear. The motor-car, properly handled, is now safer and more convenient than animal power, even at double the speed. The range of distance for pleasure driving is five times as great as we could ever hope for with horses, and, while they will not disappear from the city or the farm, a great bulk of the work hitherto done by them will be performed by mechanical power.

"The owner who is not himself the driver of a touring car loses nine-tenths of the pleasure that is to be derived from an automobile, and, for this reason, manufacturers should aim at great simplicity, as the more complicated the control, the greater the demand for an expert driver. The complaint that motor-cars are handled by inexperienced and reckless drivers arises from an evil that will, I think, cure itself. The risk that owners take when motor-cars are badly handled of having damage bills to pay will secure to the general public a high grade of skill in driving, and it seems to me unnecessary to attempt by regulation, examination, and licence to overcome this difficulty."

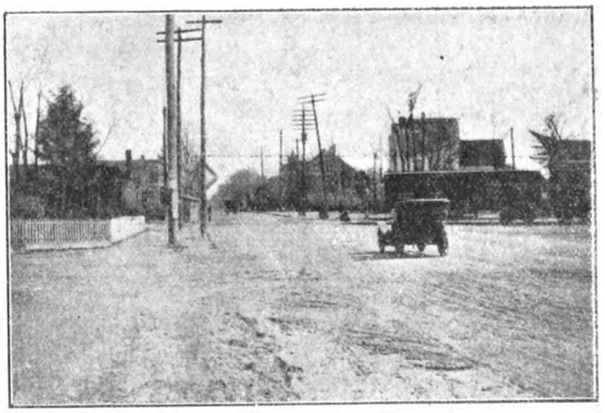
The Vanderbilt Cup Race.

THE first race for the cup presented by Mr. W. K. Vanderbilt, jun., was run off on Saturday last on Long Island, U.S.A., and was unfortunately attended with a fatal accident. The course over which the race was held is 30·2 miles long, and had to be covered ten times; in shape it is an elongated triangle, the base lying to the eastward between Plain Edge and Jericho and the apex of the triangle being at Queens. The starting point was at Westbury, on the north side of the triangle, toward the base. There were two "controls" on the course, one of three minutes and one of six minutes, at Hicksville and Hempstead, respectively. The start took place at 6 a.m. in the presence of a large number of spectators, for the more favoured of whom a grand stand had been erected. Eighteen entries were in all received, and these all appeared at the post, being despatched at intervals of two minutes, in the following ord

Mr. E. R. Thomas at the Wheel of his 60-h.p. Mercedes. At his side is Mr. E. E. Hawley, who drove the Car in the Race.

No.	Driver.	—	Car.	Country represented.
1	Campbell Muir	60 h.p.	Mercédès	Germany.
2	Gabriel	90 h.p.	De Diétrich	France.
3	Tracy	40 h.p.	Royal	America.
4	Webb	60 h.p.	Toledo	America.
5	Arents	60 h.p.	Mercédès ...	Germany.
6	Lytte	24 h.p.	Toledo	America.
7	Heath	90 h.p.	Panhard	France.
8	Hawley	60 h.p.	Mercédès	Germany.
9	Werner	60 h.p.	Mercédès	Germany.
10	Sartori	90 h.p.	Fiat	Italy.
11	Bernier	90 h.p.	Renault	France.
12	A. Clement ...	80 h.p.	Bayard-Clément ...	France.
14	Tart	90 h.p.	Panhard	France.
15	Teste	90 h.p.	Panhard...	France.
16	Schmidt... ...	30 h.p.	Packard	America.
17	Croker	75 h.p.	Simplex	America.
18	Wormser ...	60 h.p.	Mercédès	Germany.
19	Wallace	90 h.p.	Fiat	Italy.

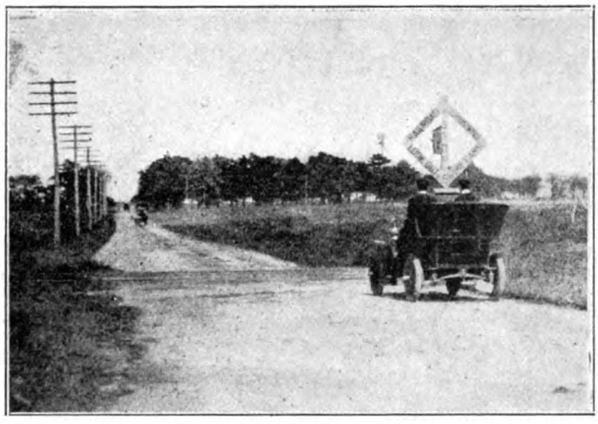


Owing to the superstition attaching to the number 13, it was purposely omitted in the allotting of the numbers to the competing cars. Sartori, on Mr. Vanderbilt's 90-h.p. Fiat, was the only one who failed to start in his proper order. Early in the morning his clutch had gone wrong, involving two hours delay in repairing. Contrary to rules, on reaching the post he made a flying start, but was stopped at Hicksville and disqualified. Gabriel was the first to complete the first round, he being followed by Teste, Werner, and Tart. Tracy, on the Royal, broke a shaft at Queens; he replaced it and re-started, but had not gone far when a cylinder went wrong, and he had to retire. Wallace, on the Fiat, No. 19, also withdrew in this round, owing to an accident to his mechanician, Dondier. The latter was leaping into the car at the Hicksville control, and fell, the wheel passing over his legs. He was removed to hospital, where he was found to be not gravely injured.

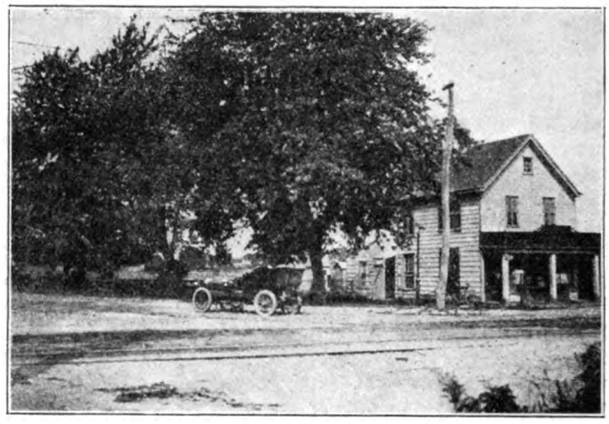
The second round saw the finish of Werner, owing to tyre troubles, while the Renault driven by Bernier broke a cardan joint when passing over a level crossing, and had to withdraw. It was in the third round that the most serious accident of the day occurred. The catastrophe happened to the 60-h.p. Mercedes driven by Arents. One of the tyres collapsed, and when the brakes were applied the car fell on its side, throwing Mr. Arents and his mechanician, Menzel, on the road. Menzel's head was cut open, and he was so badly hurt otherwise that he died before he could be given proper medical attention. Mr. Arents was also very badly injured, and now lies in the hospital in a precarious condition suffering from a fractured skull. Gabriel, too, had a narrow escape from a railway train at a level crossing at Mineola, the officials signalling the train first to stop and then to go on. Both the car and the train went on, Gabriel whizzing by first with only a few yards to spare. Teste (Panhard), who had made the best time during the first lap, passed the starting line first on the second and third rounds, but had to abandon shortly after for tyre and other troubles, details of which are not yet available.

Heath had now run into first place, followed by Clement, Gabriel, and Tart. The fourth circuit was made without accident and without change in position, but in the fifth round Hawley (Mercédès), withdrew near the grand stand owing to a broken front spring, the car having swerved off the road while

Near Hicksville.

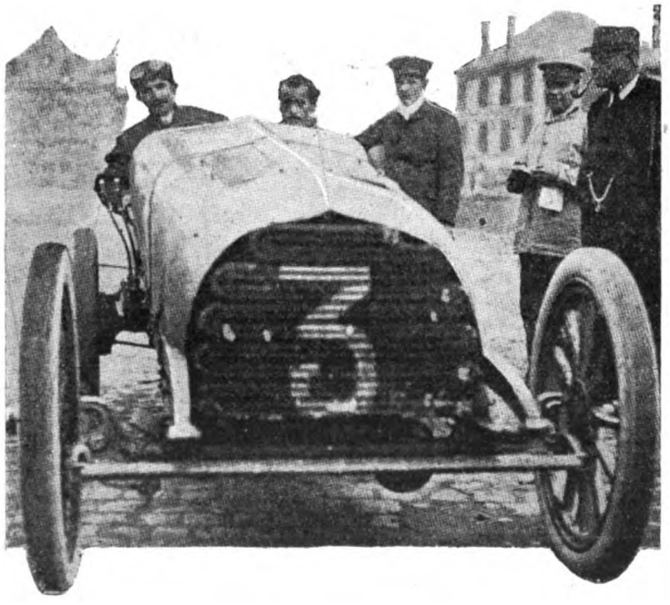


The Railway Crossing at Hicksville.



Digitized by Google

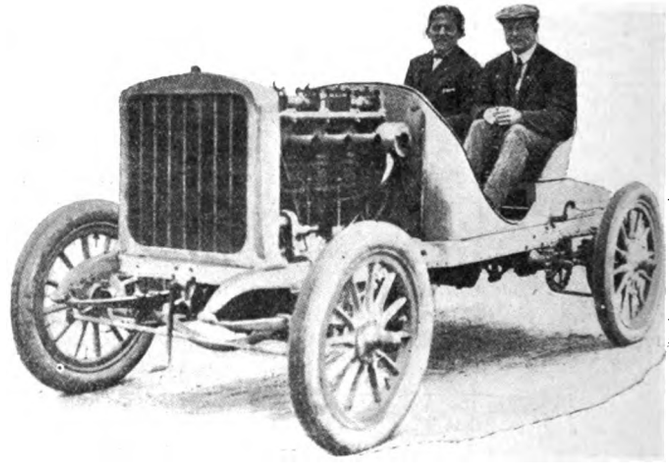
taking an abrupt turn. Croker (Simplex), who had lost nearly an hour in the first lap owing to tyre troubles, also abandoned after completing five circuits. Heath (Panhard) led at the end of the fifth round, his time for the distance of 151 miles being 3 hours 1 min. 5 sec. The only change in the sixth round was that Tart gave way to Lyttle for the fourth place, 43 minutes separating the latter from Heath, the first man. Gabriel had bad luck in the seventh round, he having the misfortune to break his crank shaft, while Wormser (Mercedes), who had tyre troubles from the outset, withdrew in this circuit. Tart (Panhard) fell out in the eighth circuit.



The race had now become a struggle between Heath (Panhard) and Clement (Clement-Bayard), and to the surprise of all the latter was the first to finish the ninth round, Heath being delayed by tyre troubles. He quickly got going again, however, and made the last circuit at a speed of about 72 miles per hour, running into first place with but 1 min. 28 sec. to spare, Clement being second and Lyttle third.

The Railway Crossing at Mineola, where Gabriel narrowly escaped colliding with a train.

A Sharp Turn near Elmont.



M. Clement, jun., on the Clement-Bayard which secured second place.

After these three cars finished the race was stopped owing to the spectators crowding on the course, the cars still in the running at that time being Campbell Muir (Mercedes), eighth circuit, Schmidt (Panhard), eighth circuit, and Webb (Toledo), fifth circuit. The net times of the three who finished were :—

1.	Heath	90-h.p. Panhard	5h. 26min. 40sec.
2.	Clement ...	80-h.p. Clement Bayard	5h. 28min. 15sec.
3.	Lyttle	24-h.p. Toledo	6h. 20min. [illegible]

Clement protested against the decision of the judges, asserting that 1 min. 40 sec. had been deducted from his running time without warrant while he was repairing a broken petrol tank. He claimed that he had therefore won the race by 12 sec. The judges, however, overruled his objection. Heath's average speed was 51·13 miles an hour, and Clement's 51·08. The weather was warm, but a refreshing north-westerly breeze was blowing during the greater part of the day. Despite the threats made by irate farmers, no attempt was made to block the roads or spoil the race, but several competitors complained of tyres being punctured through nails and broken glass, which, it is believed, were maliciously scattered on the course. The level crossings proved a source of danger and trouble throughout the race.

The result of the contest was full of surprises. Of the eighteen competitors no less than twelve retired. Not one of the five Mercedes nor either of the Fiats completed the ten laps, while out of five American entries only one was classified. The honours of the day fell to France, the contest proving a battle of giants between Panhard and Clement, only a matter of 88 sec. separating them at the finish.

Mr. A. C. Webb's 60-h.p. Toledo Racer.

A GARAGE and show rooms could be formed of some premises in Oxford Street, extending to the rear in Tenterden Street, which Messrs. Beal and Myrtle have to let.

THE Lion de Beau Sejour Brewery Company at Nyon, Switzerland, is in the market for a motor-lorry capable of carrying a load of six tons at speeds up to seven and a half miles per hour.

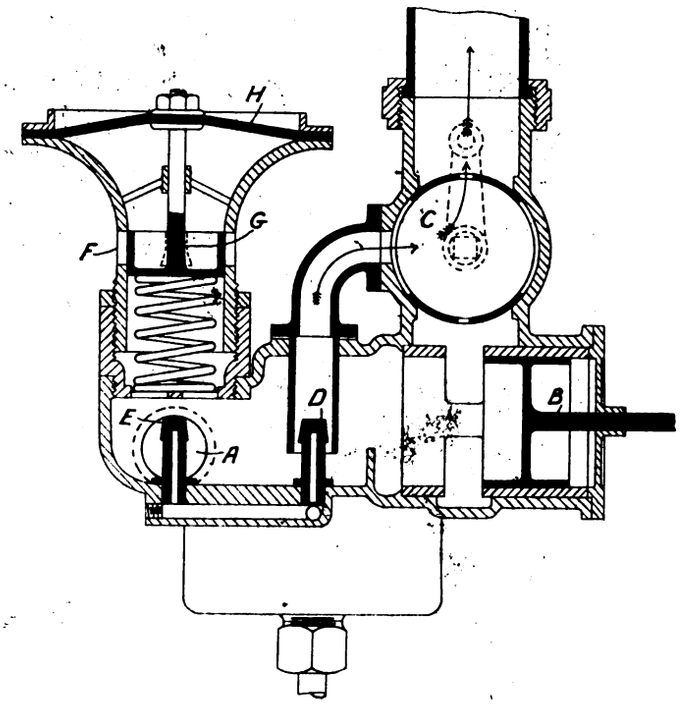
OILING THE ROADS.

THE Secretary of the Chamber of Commerce of Los Angeles, Cal., has recently made an interesting communication on the subject of the use of oil on roads for the purpose of overcoming the dust nuisance. In the course of the report he states:—

"For the past four or five years the use of oil on our roadways has been increasing rapidly, and is now considered the best method for laying the dust, as well as of making a serviceable roadway. It has been taken up by the different boards of supervisors in the surrounding counties, as well as by the superintendent of streets in Los Angeles, and we have now in the neighbourhood 300 or 400 miles of oiled roads within a radius of 60 miles of the city. It has been found, when properly applied and the necessary attention is given to it, that it forms a smooth, durable surface; and in one case of a road with a 6 per cent. grade treated with oil, it was found after a heavy rainstorm the road had not cut or washed, but on a road in the same neighbourhood under the same conditions not treated with oil it became impassable.

"The process of preparation varies considerably according to the opinions and experience of the different workers, as well as with the different material of which the roadbed is composed. Some officials have claimed that a very sandy road would not be benefited with oil, but by repeated experiment it has been found that by putting on a very heavy coat of oil the loose sand has taken it up, and by continual application a very fair roadbed has been made out of what was almost impassable sand. In some instances sandy roads have been first crowned up with a heavier soil or with clay, making a firm foundation, and then treated with oil, thus making as good a road as in other sections where the land is heavier. In some localities, where oil has been used for some time and careful attention given to repairs and renewal, the roads have become as smooth and hard as asphalt pavements and without the disadvantage of dust. In preparing an ordinary road, in some instances the surface has been loosened by a machine carrying something in the nature of a rake, for the purpose of being able thereby to mix the oil with the surface dirt. In others, where the soil is heavy and packed hard, it has been covered with oil and then a thin coating of light sand is sprinkled over this, which causes the whole to cement together, forming a hard surface. For roads of this nature, that is with a hard surface, it has been found preferable in many cases to use a light gravity oil, which is absorbed readily by the earth. In cases of light or sandy soil, it is contended by many that the heavier oils carrying more asphalt in their composition are more desirable and more effectual for the purpose.

"It is a hard matter to give any definite figures as to the cost of treating roads, for the reason that conditions differ and prices of material very in the different localities; but from the figures given by some of our supervisors it seems that it takes from 75 to 250 barrels of oil per mile for the first treatment, according to the character of the soil. About one-third of the original amount is sufficient for the second year, and thereafter in constantly decreasing amounts. It is stated that the average cost, taking the first application and the later attention, should not exceed £20 per year per mile. It is authoritatively claimed that treatment by oil is much less expensive, even at the outset, than the use of water in laying the dust, and at the same time is enduring."



MR. C. BADDELEY has been appointed manager of the Midland Motor Co., whose works in the Ladywood Road, Birmingham, have been re-organised.

THE covers and tubes now being offered by the Acre Rubber Company are renovated ones; the word "renovated" having been inadvertently omitted from their advertisement on page xx. of last week's issue.

THE Belper Rural District Council have advised the county authorities for Derbyshire to ask for a restriction of the speed of cars in their area; but the County Council has declined to take action.

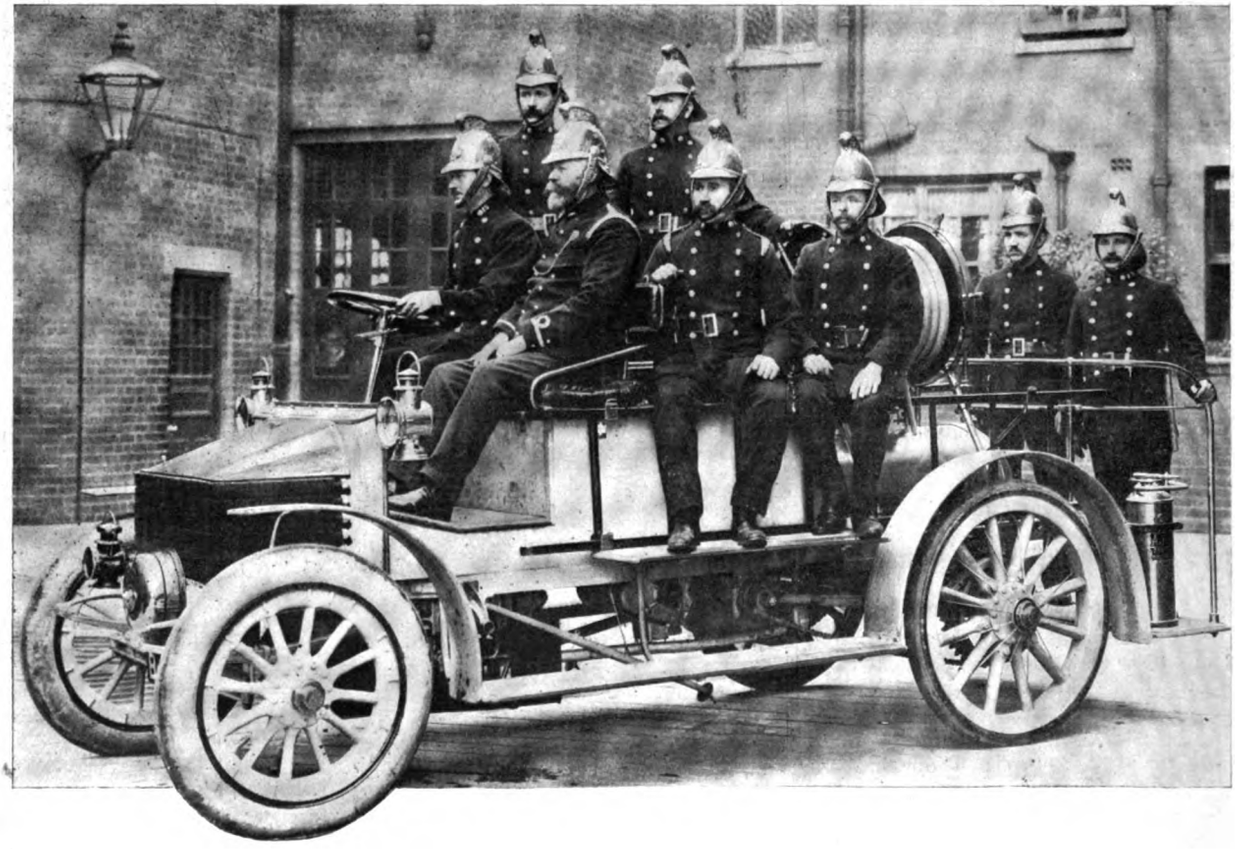
THE BROOKE AUTOMATIC CARBURETTOR.

THE accompanying drawing gives a sectional view of a new automatic carburettor which Messrs. J. W. Brooke and Co., Ltd., are now fitting to their 15–20-h.p. cars. It will be seen that the carburettor is fitted with two jets and an ordinary float chamber, with the exception that the level of the petrol in the chamber is adjustable. The piston rod and piston B are worked from the governor, which normally cuts out at an engine speed of about 900 revolutions per minute, any speed above this being obtained by means of the foot accelerator. C is the hand throttle, which is shown in the cut off position at which the engine will run at its very slowest, the throttle being adjusted to effect this when the motor is on the testing stool. When the engine is running with the hand throttle in this position only one jet, the one marked D, is in operation, the gases passing in the direction of the arrows. A is the inlet for the hot air, which passes over the jet E, and in the ordinary course of things passes by the second jet D, and through the other opening of the hand throttle. The auxiliary air is admitted by means of the holes F, the aperture of which is regulated by

the piston G working on a flexible rubber band H, and is controlled by the suction set up by the engine. With the new carburettor Messrs. Brooke claim that they can run the engine from as low a speed as 97 revolutions per minute when standing or when pulling, to about 1,500 revolutions, this giving, of course, great flexibility to the motor and at the same time very quiet running.

A BATTERSEA motorist has been fined 3s. and costs for taking water from the Mount Pond, Clapham Common, for his motor-car.

WHEN the North-Eastern Railway Company suspends its service of motor-'buses from Ripon to Studley Royal, a short service of three stages is to be instituted.



AT the Crown Stables on the South Cliff Esplanade at Scarborough, Messrs. T. and J. W. Rines have accommodation for motor-cars. There is "an inspection pit and shoeing forge in the yard."

MR. R. WOODHEAD has opened a garage in the centre of Southport, at 35, Nevill Street. Spare parts will be stocked, and on receipt of message engineers can be sent by motor-cars to any part of the district either day or night.

Digitized by Google

THE LEICESTER MOTOR FIRE ENGINE.

WE are now able to give an illustration of the 24-h.p. chemical fire engine which the Wolseley Tool and Motor Car Company, Limited, have lately completed for the Leicester Corporation Fire Brigade Committee. The vehicle has been constructed to comply with the requirements of Superintendent Ely, the chief officer of the fire brigade at Leicester, who is seen seated by the driver. The vehicle has a specially built *chassis* with a 9 ft. 6 in. wheel base, and 4 ft. 9 in. track. The employment of the standard Wolseley horizontal type of engine renders a very large proportion of the *chassis* available for the fixture of the various fire brigade appliances. The wheels are of artillery pattern, the rear ones being 40 in. diameter and shod with Sirdar solid tyres, and the front 36 in. diameter and fitted with 5 in. Colliers. The rear wheels are specially reinforced with wire spokes to withstand very severe strains. The *chassis* is fitted with a 24-h.p. horizontal petrol motor running at a speed of 750 revs. per minute. The cooling is on the usual "Wolseley" lines with the addition of a fan fixed inside the radiator. The engine is geared to speeds up to twenty-five miles per hour, the transmission mechanism being in accordance with the standard "Wolseley" practice. The rear part of the vehicle is fitted with a 50-gallon chemical cylinder, with hose-reel mounted above it. Besides other first-aid appliances, the vehicle carries two 9-feet ladders and two hand extincteurs. There is accommodation for eight firemen, including the driver.

The Wolseley Chemical Fire Engine built for the Leicester Fire Brigade.

During the trial runs at Leicester the vehicle proved very satisfactory, and several deputations from other towns who attended expressed themselves very favourably in regard to its easy control, and the celerity with which it could be got from point to point. When the deputation from Glasgow was travelling on the car, the chairman of the Glasgow Fire Committee unfortunately came into contact with a horse's head as the engine was going by a cart, and was thrown into the roadway, breaking his leg. This unfortunate occurrence was due entirely to the negligence of the man in charge of the horse and cart, it being admitted by those on the vehicle that it was only owing to the smart way in which the fire engine was handled that a bad smash-up was avoided.

SOME USEFUL NOTES.

BECAUSE of the small opening through which petrol must pass on its way from the tank of a motor-car through the carburettor, it is important that it be kept as free as possible from all foreign matter. An extremely small quantity of petrol is used per cycle, and its flow is controlled by admitting it through a very contracted opening, especially when the engine is running slowly under throttle; therefore, the flow, if not stopped altogether, will be unduly retarded and made irregular by a very small obstruction. Thus the proper proportion of petrol vapour and air in the explosive mixture, which is the very life of a petrol engine, will be disturbed, and the motor will either fail to develop the proper power or it may stop altogether. Some carburettors are quite sensitive to water, and a little of it in the petrol has been known to cause untold trouble.

◆ ◆ ◆

IT is therefore of prime importance that all petrol be carefully filtered when it is put into the tank, and as this is quickly and easily done, there is no excuse for neglecting this most reasonable precaution. A little care while in the peace and quiet of the motor house may save a serious *panne* either in the city surrounded by the inevitable crowd, or off in the country, miles from anywhere. Taking a clogged carburettor apart, cleaning it and putting it together again on the road, even under the most favourable circumstances, is an experience one is not likely to forget or care to repeat. Some troubles cannot be guarded against, but dirty petrol is something which need never cause inconvenience. Therefore, let it be repeated, petrol should

Digitized by Google

always be carefully filtered, ever bearing in remembrance the trite little proverb about the comparative value of a small amount of prevention and a much larger quantity of cure.

◆ ◆ ◆

FINE wire gauze, cloth and chamois are used for filtering petrol, and probably all three materials do the work fairly well, but acting on the principle that whatever is worth doing is worth doing well, it seems best to use chamois for this purpose; it is certain that neither water nor dirt will go through chamois, though petrol flows through it with surprising freedom. A common method of using chamois is to spread it over a funnel and then pour the petrol through it, but this way is open to objections; the leather lies against the funnel and hinders the free flow of the spirit, and this occasions a waste of time and also of petrol through evaporation. The next time the filter is used the dirt strained from the petrol the last time it was used will be washed into the tank, unless care is taken to always use the right side of the filter. At any rate, both funnel and chamois are liable to be dirty, unless they are put away and kept more carefully than is commonly done.

◆ ◆ ◆

A GOOD funnel and filter combined is made by taking a tin can or pail of suitable size and provided with a shut-over cover, and suspending a circular piece of chamois in it by sewing it to a wire ring fitting the inside of the can and held near the top by three little tin lugs soldered to the inside of the can; a spout soldered into the bottom at the corner and provided with a cap completes the device. The chamois should bag down, but not quite touch the bottom of the can. The cover keeps the filter clean, and to a considerable extent prevents the evaporation of the petrol which is left in the leather, and the cap on the spout contributes to the same end. This filter works very rapidly, as there is a large area to the filtering medium, and it all hangs clear of any obstruction, besides having considerable pressure on the lower part when the filter is kept nearly full.

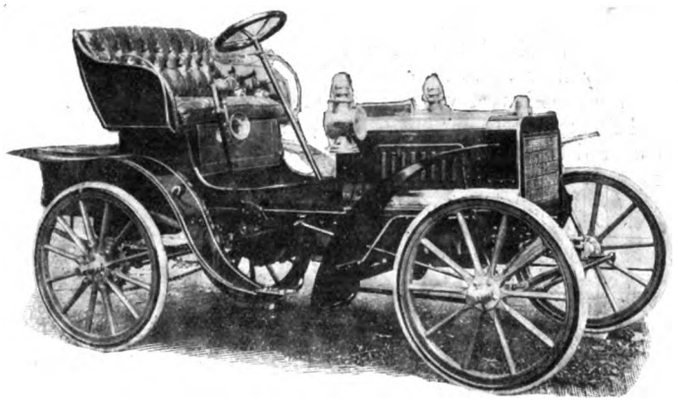
◆ ◆ ◆

THIS filter is convenient to carry if one is travelling beyond the capacity of the tank. Of all times, one should be most careful not to get dirt or water into the tank while away from home, and it is not only less trouble to have one's own filter-funnel always at hand, ready to use, but it is also far safer to use it when taking in petrol at all sorts of places, in preference to the dealer's funnel, which may be both wet and dirty. A can four inches in diameter and four or five inches deep is, remarks a writer in the "Horseless Age," a good size to use, and, of course, is less bulky to carry than a larger one.

◆ ◆ ◆

A METAL pipe, if broken off, can be temporarily repaired by connecting the broken ends with rubber tubing or hose of the right size and binding the ends tightly with wire or twine. A small leak may be stopped with tape and a large one with a piece of patching rubber held down by tape. In making use of rubber cement, patching rubber, tyre tape, rubber tubing, or anything made of or containing rubber in any form, it should be borne in mind that rubber is soluble in petrol and will not hold it long.

◆ ◆ ◆



IF one is not sure as to the direction the ignition lever moves to advance or retard the ignition, it can be found as follows:—Turn the starting handle slowly in the direction which the motor will run when in operation, and note the way the make and break disc runs. When the blade is moved in the same direction as the disc turns, ignition is retarded, and when moved in the opposite direction, it is advanced.

◆ ◆ ◆

THE question of foot-warmers is a burning one with motorists at this season of the year, and an efficient arrangement to this end adds much to the comfort of driving. Many automobilists have fitted arrangements whereby a branch from the cylinder cooling water circulation is made to pass round the floor of the vehicle. Where an ordinary foot warmer is employed its efficiency may be much increased by using acetate of soda for filling it instead of water. The crystals contain about 40 per cent. of water, and if a sufficient quantity of them to fill the warmer is heated with half a pint or so of additional water, till they melt in their own water of crystallisation, the solution will boil at nearly 250 deg. F., and will remain hot much longer than plain water. The solution crystallises on cooling, and the warmer must be reheated by placing it on the kitchen range; hence the pattern with flat base and aperture at the top is most suitable. Though an old method for railway foot-warmers, this may be new to some readers.

THE THOR PETROL CAR.

A NEW addition to the list of popular-priced two-seated cars is the Thor, of which an illustration is given herewith. The vehicle, which is being manufactured by the Thor Motor Car Company, comprises a number of special features, chief amongst which is the method of suspending the frame to enable the use of solid tyres in place of pneumatics. The frame, which is of channel steel construction, is suspended at three points, there being two double elliptic side springs at the rear and a transverse semi-elliptic spring at the forward end, this being connected by links to the front axle. The motive power is supplied by a vertical double-cylinder engine developing from 6-h p. to 8-h.p.; the ignition is of the usual high-tension type with trembler coil, while the mixture is furnished by a Rover automatic carburettor. The water circulation is maintained by a gear-driven rotary pump and a special ribbed pipe radiator set in a frame which forms the tank; the system is so arranged that,

should the pump fail, the circulation of the water will still be maintained by gravity. The inlet valves, which are of the suction type, are located on the top of the cylinder heads, and are fitted in such a way that they can quickly be removed when necessary. The control levers for the ignition and throttle—which latter acts directly on the carburettor—are grouped on the steering column, the connections being by light chains instead of the usual wires.

Passing to the transmission, the power is conveyed through a leather-faced internal cone clutch to a gear box giving three speeds forward and a reverse, all controlled by one lever with direct drive on top speed. From the differential countershaft side chains convey the power to the rear road wheels. The steering is of the worm and nut type, actuated by an inclined hand wheel; while as to brakes, a pedal controls one of the contracting band type on the differential shaft and a hand lever shoe brakes acting on the rear wheel tyres. The road wheels are 30 in. in diameter, shod with 1½ inch Clincher solid-rubber tyres. The vehicle complete weighs about 11 cwt. and can attain a speed up to twenty-five miles per hour. The seat is wide, while the footboard affords plenty of leg room; a large tool box is provided at the rear. The car appears to be well constructed throughout, a detail to which attention may be drawn being that the nuts are either pinned or provided with lock nuts. The Thor Company are also introducing a double purpose car on the same *chassis*, it being provided with a 5 cwt. van body in addition to the two-seated passenger body, so that either can be readily substituted for the other.

THE BLACKPOOL MEET.

WITH the approach of the day of the motor meet at Blackpool, interest in the event increases, and, given bright autumnal weather, nothing seems likely to occur to mar the complete success of the trials. The local arrangements are complete, and caution boards have been placed along the main thoroughfares of the town to assure absolute freedom from accidents. Since Sunday the track has been open from 6 a.m. to 8 a.m. for trial runs, and several of the competitors have taken advantage of this, afterwards speaking in glowing terms of the suitability of the course.

Blackpool boasts of a promenade over three and a half miles in length, from which three magnificient piers—the North, Central and Victoria—jut out into the sea. The course lies between the Victoria pier, which is at the extreme south of the promenade, and the Central Pier, a distance of about a mile and a half separating the two. Two years ago the stupendous work of widening the whole of the promenade was begun, and it is upon the completed section that the trials will take place. Twelve months since such an event in Blackpool would have been almost an impossibility. The track, which is constructed of asphalt on a concrete bed, is in perfect condition, having only been in use during the past summer. The surface is perfectly even, and the course being practically straight, some record speeds should be accomplished. At the finishing point, which is near the Manchester Hotel, a little south of the Central Pier, a grand stand is being erected to seat over 1,000 persons, and already a large number of applications for reserve seats have been received, the Manchester Automobile Club having written for fifty seats to be set aside for them.

The event is receiving a large amount of local support and a good financial backing has been forthcoming in the town itself. The committee have secured many well-known public men as guarantors in sums ranging from £20 to £5. Ald. J. Duckworth (of Rochdale), the Liberal candidate for Blackpool, is amongst the guarantors for £20. The leading cup, which is a very handsome one, is being given by the Mayor of Blackpool, several ex-mayors, and town councillors; and this will be offered for competition in the class for the large racing cars corresponding to those that compete in the Gordon Bennett cup races. Mrs. Wilfred Ashley, the wife of the Conservative candidate for the town, Messrs. Bass, Ratcliffe, and Gretton, the Blackpool Tower Company, the Blackpool Winter Gardens, the Hotel Metropole, the Imperial Hydro, Messrs. Magee, Marshall and Co., Mr. T. Sergenson (of the Grand Theatre), Messrs. Worthington and Co., and Mr. Humphrey Walker, who is taking an active part in the local arrangements, also figure amongst the donors of other cups, varying in value from twenty to fifty guineas each. The appointment of Colonel Holden and Mr. Mervyn O'Gorman as judges has been noted with much local satisfaction.

Now that the season at the popular northern seaside resort has practically come to an end, the automobilists' visit is the talk of the town, for the event comes as a novelty in a place where, within a twelvemonth, nearly every conceivable form of sport, amusement and recreation may be witnessed.

Local authorities fully anticipate that the trials will attract a large number of visitors, apart from motorists, from all parts of the country, but particularly from the industrial towns of Lancashire and Yorkshire, the inhabitants of which will be specially catered for by the Lancashire and Yorkshire Railway. It is an open secret that the Blackpool Corporation look to the event to do something to establish an autumn season, towards which their efforts have been directed for several years past. It may be taken for granted, therefore, that everything will be done for the comfort and convenience, not only of those taking part in the trials, but of motorists in general, and of the ordinary visitor, to whom the possession of a motor-car is as yet a dream of the future. Arrangements are being made for the accommodation of a large number of cars, and in the town will be found at least one fully equipped garage, capable of dealing with any emergency that may arise, while the Central Garage will be found to have ample facilities for storing vehicles.

To those motorists who elect to stay over Sunday, a variety of day trips will present themselves. A popular run is to Lancaster, a distance of about thirty miles. Farther afield is the pretty little town of Kirkby Lonsdale, whilst Windermere, and the natural attractions of the Lake District generally, will no doubt be irresistible to the more ardent spirits.

The boisterous westerly gales which have swept the Lancashire coast during the past few weeks have now given place to conditions more favourable to high speed tests, so that there is every prospect of a most successful meet, both from the practical and social point of view.

The entries received up to the time of going to press were as follow:—

Classes A and 2.—Cycles up to 170 lbs.—W. Andrew, Fleet motor-cycle; E. T. Jones, Humber motor cycle; Bat Motor Manufacturing Company, Bat motor-cycle.

Class B.—Cycles unrestricted as to weight.—E. T. Jones, Humber motor-cycle.

Classes C and S.—Cars costing £250 or under.—Speedwell Motor Company, 10-h.p. light car; Anglo-American Motor-car Company, 8¼-h.p. Cadillac; W. G. Crombie, 8-h.p. G.M.C.C.; E. W. Lewis, 8-h.p. Rover; H. Belcher, 8½-h.p. Humber; R. Lord, 10-h.p. Vulcan; W. Bottomley, Ribble voiturette; Star Engineering Company, 7-h.p. Star.

Classes D. and T.—Cars costing £500 or under.—A. Huntley Walker, 15-h.p. Darracq; W. Crombie, 24 h.p. G.M.C.C.; J. R. Richmond, 15-h.p. Darracq; H. Belcher, 20-h.p. Humber; London Motor Garage Company, 12-h.p. Pipe; Vauxhall Iron Works Company, 12–14-h.p. Vauxhall; A. W. Walton, 15-h.p. Darracq; Star Engineering Company 12-h.p. Star; M. Hawnt, 10-12-h.p. Motobloc.

Classes E. and V.—Cars costing £750 or under.—A. Huntley Walker, 30-h.p. Darracq; T. Thornycroft, 24-h.p. Thornycroft; London Motor Garage Company, 20-h.p. Pipe; E. H. Lancaster, 20-h.p. Clement; Beaufort Motor Company, 24-h.p. Beaufort; C. E. Oliver, 15-h.p. G.C.V.

Classes F. and W.—Cars costing up to £1,200.—Speedwell Motor Company, 24-28-h.p. Leon Bollee; Orrell Wren, 35-h.p. Napier; Leon Bollee Syndicate, 40-h.p. Leon Bollee; J. R. Freme, 18-22-h.p. Mercedes; R. St. J. Willans, 24-h.p. Rochet Schneider; London Motor Garage Company, 25 h.p. C.G.V.; Miss Dorothy Levitt, 20-h.p Napier; J. E. Baxter, 50 h.p. Wolseley.

Classes G. and X.—Cars irrespective of cost.—Speedwell Motor Company, 28-h.p. Leon Bollee; Speedwell Motor Company, 45-h.p. Leon Bollee; C. Cordingley, 60-h.p. Mercedes; Andrew Fletcher, 60-h.p. Mercedes; L. Williamson, 60-h.p. Mercedes; R. St. J. Willans, 24-h.p. Rochet Schneider; Cecil Edge, 65-h.p. Napier.

Classes L. and F.—Racing cars weighing less than 1,000 kilos.—C. Jarrott, 45-h.p. De Dietrich; A. Fletcher, 90-h.p. Mercedes: Clifford Earp, 80-h.p. Napier.

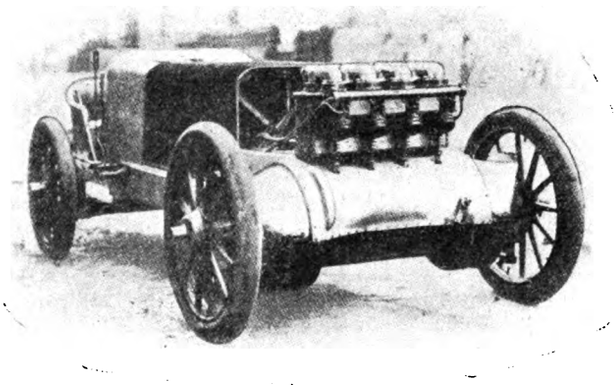
THE Malton Agricultural Club has passed a resolution deploring the speed of motor-cars on Yorkshire highways.

A MOTOR-CAR service is being suggested from the Finchley Road railway station to Hampstead Heath by way of Frognal.

THE Australian customs authorities have given a decision to the effect "that motor-car chains not accompanying motors" are to be classified as "chains n.e.i." and admitted free of import duty.

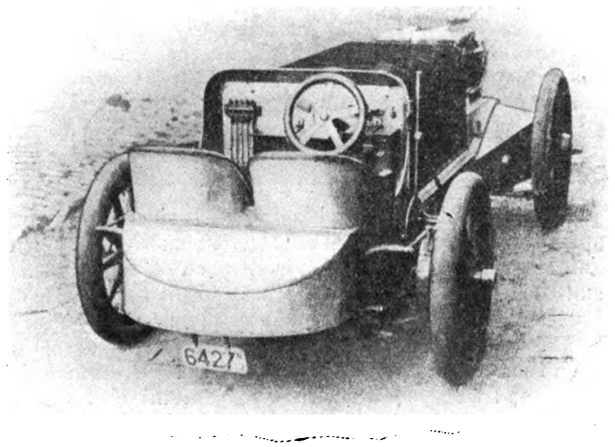
ALWAYS look at both sides of a punctured inner tube, to ascertain whether the puncturing object has penetrated the under as well as the upper portion of the tube, and thus perhaps save a second dismantling of the tyre.

WHEN a punctured inner tube is removed for repair, pass the hand round inside the cover in order to feel whether the puncturing object remains imbedded in it. If it can be found, it serves at once as a guide to the position of the hole in the inner tube, and by removing it the risk of the same object inflicting a second puncture at or near the former place is avoided.



THE admission and exhaust valves should work freely, and need very little attention. Through too free oiling or too rich a mixture they may become clogged with soot, when the valve should be removed and washed in paraffin or petrol. The spring should be freed, and the valve turned several times on its seat by means of a screwdriver, adding a drop of paraffin. Should the seating of the valve show a bright ring all round its circumference, the valve and seat may be replaced, but if this bright ring does not show, the valve must be ground in with the finest emery flour and oil, and the whole carefully wiped clean and replaced.

Digitized by Google

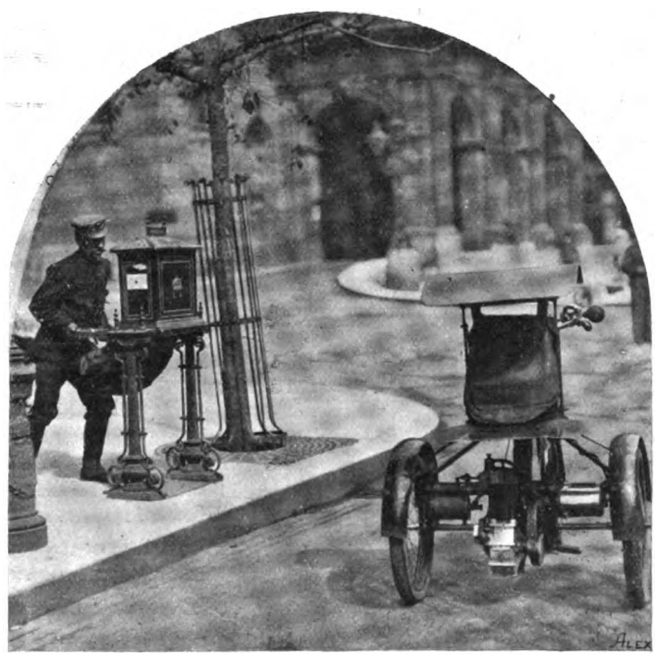


HERE AND THERE.

THE Hon. James Hozier, M.P., has joined the Western Section of the Scottish Automobile Club.

A SOMEWHAT novel racing car has just been completed in New York to the designs of Mr. Walter Christie. The feature of the vehicle, two views of which are given herewith, is found in the fact that no front axle is used, its place being taken by the four-cylinder motor, which is geared direct on to the front wheels,

Front View of Christie Racer.



Rear View of Christie Racer.

which thus act both as drivers and steerers. The engine, whose cylinders are 6¼ in. bore by 6½ in. stroke, has a flywheel at each end fitted with taper clutches directly engaging the motor to the wheels. The motor and transmission is supported on spiral springs, the frame of the car being attached to projections cast on the engine crank case. The driver's seat is located behind the rear axle; the car has a wheel base of 8 ft. and weighs complete 1,800 pounds.

MESSRS. BROWN BROS., LIMITED, have sent us a sample section of the "Duco" puncture-proof non-skidding band for the tyres of motor-cars and cycles they have lately introduced. The band, which has steel studs inserted in the double tread, is made of specially prepared chrome leather with the sides pared down to enable the band to fit snugly around the tyre. Heat, cold, or damp are claimed to have no effect on the bands, which are vulcanised on to the outer cover; they are made in all sizes from 50 mm. by 650 mm. up to 90 mm. by 1,360 mm.

RECENTLY we had the pleasure of looking over the Victoria Garage of Messrs. Mann and Overton's, Limited, at 7a, Lower Belgrave Street, S.W. The premises, which are open day and night and are quite close to Victoria Station, can accommodate about 60 cars, and have every convenience for washing, etc. An inspection pit and accumulator charging plant are installed, while a large supply of petrol and accessories is kept on hand. Since our last visit a repairs department has been added, this being equipped with machine tools to enable all classes of repairs to be carried out.

Collecting the Mails by Motor-Cycle in Budapest.

The Hungarian Postal Authorities have lately introduced motor-cycles for the collection of the mails in the capital. A special form of letter box has been adopted to facilitate the rapid emptying of the same, while the machines are provided with a covered platform on which the mail bags are carried.

THE Central Motor Works have been opened at Greengate, Keighley.

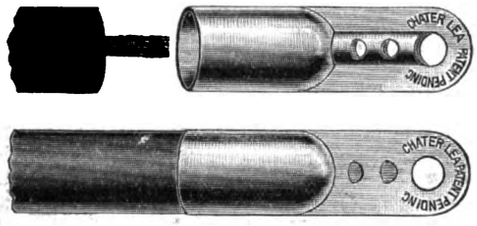
THE Bleriot lamps and generators were awarded a gold medal at the St. Louis International Exhibition.

MESSRS. HARVEY FROST AND COMPANY, the makers of the H.F. Vulcaniser, have received several orders from Australia, South America, Germany, and other continental countries.

HUBBARDS MOTOR AND ENGINEERING COMPANY, LIMITED, have established plant at their works at Much Park Street, Coventry, which enables them to undertake motor-car repairs of all classes.

THE Grand Duke William Ernst of Saxony recently visited the Dixi motor-car factory at Eisenach, Germany, travelling from his summer residence, Wilhelmsthal Castle, in a 12-15-h.p. Dixi car. After passing through the various departments of the motor-car section, where all parts of the cars with the exception of the tyres are turned out, the Grand Duke with his suite drove to the shooting range, where one of the company's quick-firing field guns was tested.

CALLING in at the works of Messrs. Dennis Bros., Limited, at Guildford the other day, we had an opportunity of inspecting one of their 20-h.p. cars with Roi des Belges body and canopy, built to the order of Sir Alfred Watkin. A similar car is also being built for Sir A. Conan Doyle. Messrs. Dennis are now building their own engines for the 20-h.p. cars. Notwithstanding the large addition to their works only recently completed they are shortly opening another factory.



A LIQUID to which the name of Petsen has been given has just been introduced by Messrs. Moore and Co., Savage Gardens, London, E.C., for scenting motor spirit. It is an agent which, added to petrol in the proportion of a tablespoonful to the gallon, is claimed to entirely remove the objectionable odour both from the spirit itself and from the exhaust gases. The makers lay special stress on the fact that the addition of Petsen to the spirit has not the slightest effect on its composition.

Digitized by Google

LORD FITZWILLIAM has, we learn, just acquired a 12-h.p. Georges Richard car.

MESSRS. A. J. BARKER AND COMPANY, engineers, have taken over the Bush Engineering Works, 5, 7, 9, 11, Bulwer Street, Shepherd's Bush, W., and have opened them as a motor works and garage.

THE Chater Lea Manufacturing Company, Limited, have sent us a sample of a new terminal for ignition wires they have

lately introduced, of which an illustration is given herewith. One advantage of the new terminal is that it can be fixed without the use of solder. The insulation is stripped off for about half an inch and the wire inserted in the groove formed for it, which is then flattened in the vice or with a hammer. This holds the wire quite securely, and as the tubular portion slips over the insulation a thoroughly neat terminal, which prevents any loose end getting to the frame, is the result. These terminals are made for high and low tension wires, and their low price should commend their use to a large number of motorists.

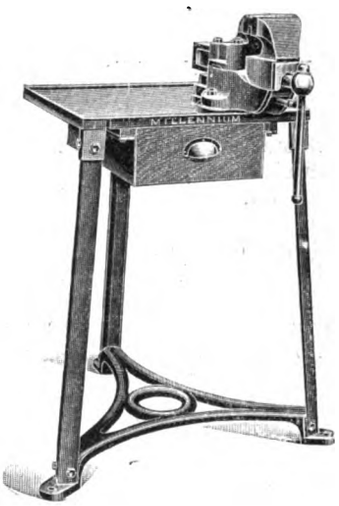
MESSRS. J. T. WILLIAMS AND COMPANY, of the Star Lamp Works, Birmingham, send us a circular descriptive of a system of acetylene lighting they have lately introduced specially designed for use on public service motor vehicles. The system has already been adopted on a number of the motor-'buses in Birmingham, and appears to be meeting with success.

MESSRS. DE DION-BOUTON, LIMITED, have just appointed the Bombay Cycle Agency, of Hornby Road, Fort, Bombay, their Indian agents for Bombay and district, and Mr. W. Newton Gill, c/o Planters Store, Calcutta, agent for the Calcutta and Madras districts.

THE American National Association of Automobile Manufacturers is about to consider the proposition of an agreement among its members regarding standard equipment. At present practice in this respect is widely divergent. Manufacturers of the cheaper cars usually include in their equipment only the most necessary articles, while those of high-priced cars make it a point to furnish a very complete outfit.

AN AMERICAN firm—the Fahnestock Transmitter Company, New York—have introduced a novel but simple form of terminal clip for ignition wiring. The device consists of a flat piece

of steel spring slotted in a longitudinal direction, and drilled at both ends. A portion of the slotted strip is bent up to pass through the clearance space formed by bending the terminal loop fashion. The end of the wire is simply passed through the eye of the narrow strip, and is held taut by the recoil action of the loop. The holes at the end of the clip are provided for attaching it to the battery or plug terminal intended. To connect or disconnect the wire it is only necessary to exert a slight pressure on the free end of the loop, when the wire may be readily withdrawn from the eye of the narrow strip. There is thus no screwing or unscrewing of screws, while the wire can be put in or taken out in one-tenth the time it takes to fix a screw, and there is no possibility of the wire being broken off.



THE Drill Hall at Blackpool is at the disposal of motorists attending the races there, having been taken over for the week by Mr. Riley, of the Central Motor Garage in that town.

IT is reported that the directors of the Suez Canal Company have decided on the establishment of a motor-car service between Ismaila and Station No. 6, where the hospital for their employees is situated.

ONE of the latest departures of Messrs. Friswell, Limited, at their depot in Albany Street, N.W., is the installation of an additional gas engine and dynamo to enable them to undertake the charging of the batteries of electrical vehicles.

SOME time ago the Bowring Petroleum Company, Limited, sent us a sample of their "All's Well" motor lubricating oil. It is a pure hydro-carbon, having a very high flash-point, while it is dark red in colour and heavy and viscid in body, the result being an oil which can be relied upon at all periods of the year. We have given the lubricant a thorough trial on an 8-h.p. car, and are able to report that, owing to its freedom from acids and impurities, it gives rise to no troublesome deposits on the valves.

THE accompanying illustration shows the Millenium vice stand lately introduced by Messrs. Lake and Elliott, of Brain-

tree. As will be seen, it is furnished with a drawer for tools, and provides a work table which should be found useful in many a motorist's private garage.

THE other day we had an opportunity of going over the extensive new premises at 110, High Street, Marylebone, W., which are about to be opened as a motor-car depot and garage by the Britannia Motor Garage, Limited, a new concern which has lately been organised by two well-known members of the trade—Mr. T. Underwood, late of the Motor Manufacturing Company, Limited, and Mr. J. H. Adams. The building comprises no less than six large floors, including the basement, access to each of which will be served by a large hydraulic lift, at present in course of installation. The extensive ground floor is to be utilised as a showroom for the sale of two new types of cars, of which particulars cannot at present be given. Some idea of the extent of the premises will be gained from the fact that garage accommodation will be available for no less than 250 cars. Plant is being installed for the carrying out of repairs of all kinds, while it is also intended to establish body building and painting departments. Needless to say, a large stock of motor accessories and petrol will be kept on hand, and that facilities for the charging of accumulators will be available. At the time of our visit the premises were still in the hands of the decorators, but business operations are expected to be commenced during the course of the coming week. When the various plans the company have in hand have fully materialised, the Britannia Motor Garage should rank among the largest and best equipped in the metropolis.

MOTOR CYCLING NEWS.

On Saturday the 100 miles non-stop run competition of the Birmingham Motor Cycle Club, for the cup presented by Mr. H. Austin, was continued. It took the form of a run to Shrewsbury and back, for the purpose of further eliminating the remaining competitors. The men left in from the previous week were Messrs. F. R. Gould, 2½-h.p. W. A. Lloyd's; E. H. Humphries, 3-h.p. Smith's; C. E. Simms, 2½-h.p. Alldays; and R. Tingey, 3-h.p. Smith's. All of these were ready for the signal to start on Saturday at 2 p.m. at the Royal Oak Hotel, Chester Road, near Erdington. The procedure of checking the men by the competitors riding together was adopted, and the officials, the hon. secretary of the club, Mr. J. R. Bedford, as judge and time-keeper, and Messrs. L. C. Davis and E. W. Winckle (observers) following behind in a 12-h.p. Wolseley car, which the president (Mr. H. Austin) had been good enough to place at the disposal of the committee. On the outward journey Mr. F. R. Gould was unfortunate enough to find that the terminal of his sparking plug had broken off, and he therefore fell out, but had effected a repair in a few minutes, caught the competitors up near Shifnal, and ran through the remainder of the journey as an observer. The remaining three were turned at the Monument, Shrewsbury, and, although the last forty miles was ridden in the dark, no more trouble was recorded till the Royal Oak was reached. A rule of the competition is that the legal limit—viz., twenty miles an hour—shall be strictly adhered to, not exceeding ten miles an hour through towns and villages, and this has been enforced. The committee have now the task before them of devising some means by which the competition may be brought to a close and the prizes awarded without running it over again, as, judging by the present condition of the machines, the competition will last indefinitely.

◆ ◆ ◆

The Motor Cycle Union of Ireland held the concluding competition of the season on Saturday last, when a one hundred miles trial took place from Dublin to Maryborough and back, for motor-cycles built for and carrying two riders. One hundred marks were allotted to each competitor, and for each stop on the road one mark was deducted. The pace was limited to a maximum of twenty miles an hour, and a minimum of fifteen, any excess of these limits entailing disqualification. The weather was very favourable, and of the twelve riders who took part eight completed the journey; the result being as follows:—

	Marks.
C. J. Lewis, F.N. fore-car	100 (max.)
T. W. Murphy, Singer with trailer	do.
H. A Evans, Singer tandem tricycle...	do.
C. B. Franklin, F.N. fore-car	do.
E. Oakes, F.N. fore car	99
Capt. Wheeler, F.N. fore-car	99
A. J. "Fenton," Peugeot fore-car	99
L. R. Oswald Sealy, Brown fore-car	95

◆ ◆ ◆

The Motor Cycle Club of Rheims has just held a petrol consumption trial exclusively reserved to motor-bicycles, over a distance of sixty kilometres—37½ miles. The conditions required that the pedalling chains should be removed, and no exhaust was allowed to impinge directly on the ground. For starting each competitor was allowed one starter to push him off a mark. Before departure the petrol tanks were emptied in the presence of the judges, and each competitor was given three litres—equal to 5·28 pints of petrol spirit. The tanks were then closed and sealed. A minimum speed of twelve and a half miles an hour had to be kept up. Nine riders competed in the test, of whom seven finished. The results were as follows:—

Rider.	Machine.	Petrol consumed for 37½ miles run.
Peron.	3-h.p. Werner.	39¾ oz.
Souplet.	2-h.p. F.N.	42¼ ,,
Roger.	2-h.p. Werner.	52 ¼ ,,
Hammling.	2-h.p. Minerva.	54½ ,,
Dieudonne.	3-h.p Griffon.	61½ ,,
Leblanc.	2-h.p. Leblanc.	79½ ,,

20 fluid oz. = 1 pint.

The result of the Rheims trial should be interesting to those riders who took part in the Auto-Cycle Club contest on the 1st inst. On that occasion the lowest consumption was equal to about 190 miles per gallon, while at Rheims the best performance was 150 miles.

The International Motor Cycle Cup, won by Demester on a Griffon. [*Le Chauffeur.*

◆ ◆ ◆

The Auto-Cycle Club is organising a 100 miles non-stop run on Saturday, November 5th, for fore-carriage machines. Starting and stopping tests on hills will be included. The route is to be in the north of London, probably starting from Barnet. The event is an open one, and further particulars can be had of the Secretary, 16, Down Street, Piccadilly, W.

◆ ◆ ◆

Apparently a morning coat is not the correct attire when motor-cycling. The Birmingham magistrates have ordered William Whitely to pay the costs for permitting the tails of his garment to obscure his identification number. Another motor-cyclist was fined for carrying a parcel by which his number was partly obscured.

◆ ◆ ◆

The committee of the Auto-Cycle Club at its meeting last week considered the question of awarding the prizes in the recent fifty-mile consumption test, and decided that, as the small allowances which should have been made had the official car not been delayed would not have made any difference in the order the event should not be cancelled. Mr. S. Harris, who rode the 1¼-h.p. F. N. Whippet, was disqualified owing to not keeping up to the official pace on the outward journey. No attempt was made to discover which was relatively the most meritorious performance, the first three with the lowest consumption being awarded prizes of equal value. These are: Rose (2½-h.p. Roc), 42 ozs.; Perman (2½-h.p. Seventy), 52 ozs.; and H. Martin (3-h.p. Excelsior), 60 ozs. Another consumption trial is to be organised early next year on altogether more scientific lines.

A 9-h.p. two-cylinder Gladiator has just gone over the course of the Automobile Club's small car reliability trial, making a non-stop run from start to finish, taking 35½ hours to do the trip. Mr. Sidgreaves drove the whole of the way

CORRESPONDENCE.

THE DUST PROBLEM.

To the Editor of *The Motor-Car Journal.*

Sir,—I was much interested in the report of Herr Westrum's paper on the abatement of the dust nuisance given in the last issue of the *Journal.* The treatment of road surfaces for the suppression of dust is of as much interest to those living along much-frequented highways as it is to motorists themselves. As concerning residents in such districts the problem may possibly be solved by the aid of some of the oiling and tarring processes now being perfected; but as it concerns automobilists the problem as such must be attacked differently if substantial results are to be obtained. There are several causes for the raising of dust by fast moving vehicles. In the first place, any irregularity in the under surface of the cars causes air currents to impinge against the road surface as the car moves along, thus stirring up the dust. An instant later a vacuum is formed by the back of the car, over the spot where the dust has thus been raised from the road surface, and the dust cloud is carried upward behind the car to fill this vacuum. This effect is particularly pronounced in cars having tool boxes, etc., projecting below the frame of the car at the rear, leaving a very small road clearance, as is the case in some large touring cars. These parts not only strongly deflect the air underneath the vehicle against the road surface, but add to the extent of the rear surface of the car, thus increasing the vacuum formed. One method of preventing dust from rising at the rear of the car is to create a strong backward blast underneath the car, preferably at the rear. The silencer discharge serves this purpose well, especially in a four-cylinder motor. If the discharge is made at the rear of the car, is inclined slightly downward, and is divided into a number of streams, it will be very effective in preventing dust from rising above the back seat and annoying the occupants.—Yours truly,

Dust Trouble.

BOWDEN WIRE.

To the Editor of *The Motor-Car Journal.*

Sir,—I regret that absence has prevented me dealing earlier with the letter signed "Owen Joseph" in your issue of the 1st inst. The writer amply confirms my contention, viz.:—That the Bowden Syndicate suffer from the lack of understanding of the principles of the mechanism on the part of manufacturers. You may remember that my whole argument was that if the comment of the judges in the Small Car Trials had been qualified by the words "as fitted" I would have had nothing to say on the subject. "Owen Joseph," however, touches quite another matter when he charges my firm with neglect, and I may assure him that it is being rigorously inquired into. It would, however, assist the investigations if he would communicate to me the date and the address from which he wrote, so that any correspondence might be more readily referred to. It is an agreeable set off to find another correspondent in the same issue commenting in the most favourable manner upon the Bowden system as fitted to his car, and I beg of you to permit me to thank that gentleman for his kindly and unsolicited support.—Yours truly,

James R. Nisbet.

SUPPLYING SPARE PARTS.

To the Editor of *The Motor-Car Journal.*

Sir,—Recently I have read several complaints from motorists regarding the neglect of manufacturers to supply spare parts. As the names of these firms were not given, it may keep would-be-motorists from going in for cars, under the impression that all makers are alike dilatory in supplying parts for renewal. I have quite another story to tell. My De Dion car met with an accident a week or two ago. I wrote to the firm in London for the parts I required, and though they could not possibly have received my letter before Saturday morning, yet the parts were delivered to me on Monday morning. If this be not a record for expeditious delivery, it is at least good enough for me.—Yours truly,

A Satisfied De Dionite.

The International Motor-Bicycle Race—Inghibert at the Dourdan Control.

[*La France Automobile.*

CLEANING THE HANDS.

To the Editor of *The Motor-Car Journal.*

Sir,—I would like to draw the attention of fellow motorists to the following tip for removing grease, etc., from the hands:—

Obtain a good lather with any household or other soap, and taking a handful of coffee grounds, proceed to work it well into the hands. After a minute or so the hands, when rinsed free of the gritty mixture, will be found to be beautifully soft, fresh and clean. No need for special motor soap where coffee grounds abound.—Yours truly,

J. Stuart Shaw.

BELT TRANSMISSION.

To the Editor of *The Motor-Car Journal.*

Sir,—I agree with "Assam" in his statements to the effect that a number of people are requiring a reliable car at a reasonable price, and that although belt systems so far have been faulty, if these faults are removed a vehicle could be produced "within reach of all," but do not see how he can hold that this should deter manufacturers from producing such,

Digitized by Google

Surely it is in the interests of all concerned that manufacturers should be able to make a car within the reach of the man of moderate means suitable for the business man and the novice.

I cannot follow the rest of his arguments, maintaining that those who want belt drives have been brought up with such transmission and have never been on a good geared car. I should imagine anyone brought up on belt-driven vehicles as at present existing would not cling to them even if they had not driven the costly-geared systems of the day, but rather that they appreciate the flexibility, sweetness, silence, and simplicity of the belt in contrast with gears, and hope to see the former perfected. Your correspondent also states that three speeds and reverse are difficult to get in without sun and planet gear, but this no longer holds good, we can get in five speeds and reverse if needed with a single belt that never slips or requires shortening, using only two pulleys, weighing about 20 lbs., and this without gear box, live axle, level drive, cardan, side chains, etc.; it needs no attention or lubrication save replenishing grease cups every week or so. We have had a single cylinder car on this system tested by running a public service for some time now, sometimes with thirteen up; moreover, although the speed changing is easier than any existing methods, we are working out a system in connection therewith that will change speed of itself to suit the road and further render the use of the brakes almost unnecessary, practically bringing the whole control to the spark or throttle. We therefore maintain that the belt is not dead.—Yours truly,

C. Dent.

A TREMBLER QUERY.

To the Editor of *The Motor-Car Journal*.

Sir,—I have for a short time had the same trouble with my car as your correspondent "Petrol" complains of in the *Journal* of the 1st inst. It was observed to commence after I had increased the inlet valve movement. I therefore imagined the cylinder corresponding was starved, and by a turn of the nut on the carburettor float increased the feed. The trouble promptly ceased and misfiring no longer occurred. I advise him to try the same remedy.—Yours truly,

F. M. Burnett.

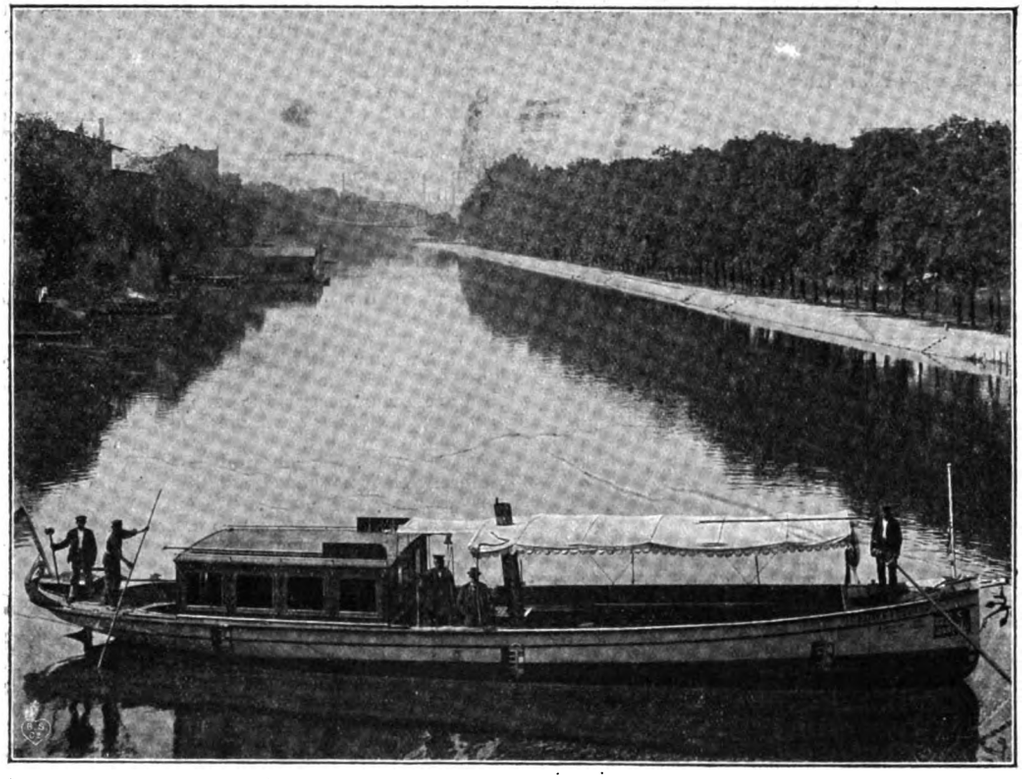
QUERIES RE PETROL CARS.

To the Editor of *The Motor-Car Journal*.

Sir,—Will any of your readers kindly inform me what they think is wrong with my car? I can get a very good spark on the plug, but only a very feeble explosion, although on advancing the sparking I can get a fairly good backfire. I have varied the mixture, but it only answers with the lever in one place. The accumulators are fully charged and ignition seems all right. I use Pratt's motor-spirit. I have tried two or three different plugs with the same results in each case.—Yours truly,

F. W. R.

[We fancy "F.W.R.'s" trouble is due to bad compression, which would cause a feeble explosion, or failing this there may be a gauze in the inlet pipe which has become choked, thereby causing a throttle on the inlet. The trouble is evidently not due to the sparking.]



HOW TO SELECT A MOTOR-CAR.

To the Editor of *The Motor-Car Journal*.

Sir,—I read with interest your article "How to Select a Motor-car," and as I am one of those who are anxious to buy a car, I shall be glad of a little further advice. I notice you say the motor is the most important part of the whole thing, and ought to be carefully examined; but what is the good of a novice examining a motor when he knows absolutely nothing about it? I myself have found the greatest difficulty in getting anyone connected with the trade to give me information about a car. Indeed, when last year in London I asked a well-known firm to give me a modest ten mile trial trip; they refused. Consequently I left without purchasing, being told no one in London would do such a thing. The question is, then, what am I to do? I have no experience, and apparently I am not going to have any until I decide to purchase and take everything that is told me as being correct.

The first question is, which is the most suitable car to meet my requirements? I live in South Devon, where hills are steep, long, and badly kept, gradients often one in six. I want a car to take the place of a good useful horse; that is to say, a car that I can run about town in, take a turn in the country (always hilly), or go on tour for a few weeks two or three times a year. I do not want to go flying about at twenty-five or forty miles an hour, or to run a hundred miles a day, but would be content with forty at most. I want a car with as few complications as possible and thoroughly reliable, one that will take the hills without shedding its load, and with brake power that will stop and hold the car at all times. I think I have stated my wants fully. I may say that I am limited to about £250.—Yours truly,

A Would-be Motorist.

The above illustration shows the Petrol Motor-Boat which the Cudell Company, of Aix-la-Chapelle, have lately completed for a public service on the river Saale, at Halle. The vessel, which can carry 120 passengers, is propelled by means of a 24-h.p. four-cylinder engine.

RECKLESS DRIVING.

To the Editor of *The Motor-Car Journal*.

Sir,—I entirely agree with "B. Y. 193" in his remarks under the above heading in the *Journal* of the 1st inst., the cars almost daily tearing down the Avenue here, at Southampton, which is about a mile above the town, covering everyone with clouds of dust. These cars are almost

Digitized by Google

invariably A———. Surley they might have the decency to slow down a little when on the outskirts of a town. There is no doubt the feeling of animosity against motorists is increasing in this neighbourhood, entirely owing to the utter selfishness of these drivers, and the result will be that, instead of having the present restrictions in any way relaxed at the expiration of the present Act, we shall be more handicapped than ever.—Yours truly,

WILLIAM F. ARCHDALE.

TYRES.

TO THE EDITOR OF *The Motor-Car Journal.*

SIR,—In reply to the letter signed "John Ansonia" in the *Journal* of September 24th regarding the collapse of his 800 by 85 mm. Michelin tyres on a 12-h.p. Darracq car after only 600 miles running, I think that the real cause of the trouble is that the tyres are too small for the weight and h.p. of the car, accentuated by a fierce clutch. According to the Michelin Company's practice the tyres in question should not carry more than 480 lbs. per wheel, and I presume that the 12-h.p. Darracq weighs 16 cwt. without passengers, and I suppose that would be about 690 lbs. per wheel with four passengers, which of course is far too much for such light tyres. I think if "John Ansonia" will have Michelin 810 by 90 (32 inch by 3½ inch) tyres fitted, at any rate to his rear wheels, he will have no further trouble, these tyres being intended to carry 950 lbs. per wheel; "John Ansonia's" letter seems to especially bear out what Mr. Filson Young remarks upon so strongly in his delightful book just published, viz., the growing practice amongst many makers or agents of sending out cars under-tyred in order to pocket a few shillings (or pounds).—Yours truly,

ATRETON.

WHERE REPAIR SHOPS ARE WANTED.

TO THE EDITOR OF *The Motor-Car Journal.*

SIR,—In reply to the enquiry by "D. H." in your issue of the 8th inst., I think Coronation Road, Bristol, would be a good position for a repairing shop, as motor-cars from the West of England for the North and Midlands would pass along here, and there is no repairer that I know of at present.—Yours truly,

H. D.

TO THE EDITOR OF *The Motor-Car Journal.*

SIR,—In answer to query by "D. H.," I should advise him to start one at Ramsgate. I have lately been staying there and there are many motor-cars in the town and district, but I did not find a repairer capable of doing workmanlike repairs.—Yours truly,

ERNEST A. EBSWORTH.

ENGINE REPAIRS.

TO THE EDITOR OF *The Motor-Car Journal.*

SIR,—I have a four-cylinder foreign-made car which I bought in January last, and I have driven it about 8,000 miles. I have been motoring now for two to three years, and generally do ordinary adjustments and little jobs myself. I think the crank, gudgeon, and other bearings in the engine and gear box require attention, but I do not feel sufficiently experienced to take the responsibility of these adjustments. I live in the country near a medium-sized town where there are only the so-called experts, and from my experience of this class of repairer I could do the job better and with more care than they give; they are at present picking up their experience at the expense of motorists, and half doing jobs.

I can take down the engine and gear; I quite understand its workings, and shall feel more satisfied if I see what is done and that all is put right. Would you or some of your readers advise me which is the best of the following courses to adopt—(a) Get a mechanic from an engineer's shop in the town near, who will only be used to gas engines and like work; (b) get one from one of the motor manufactories; (c) or send the parts to a motor factory to have the bushes and bearings set. Some bearings may—and do, I believe—require new brasses and bushes. With regard to the engine, there is decided play in both the connecting rod crank bearings and also at the gudgeons. As to the connecting rod bearings on the cranks, I understand these can be filled up with metal or reduced to take up the wear. Which is the proper plan, and if they can be reduced before adopting the filling, how much is the maximum play that should be so taken up? Should ordinary engineers' mechanics understand the filling process? I am well equipped with tools, and am having a pit made. Lathe work can be done near.

I want to be able to judge that the work is being done right, and I should be glad of any hints as to the adjustments of bearings. My car has proved a complete success, and I am anxious to give it every attention during the winter in the way of taking up wear in order that I may commence next season with every confidence of it doing another 8,000 or 10,000 miles as well as hitherto.—Yours truly,

X. Y. Z.

[*Kossuth.*

MECHANICALLY OPERATED INLET VALVES.

TO THE EDITOR OF *The Motor-Car Journal.*

SIR,—The mechanically operated inlet valve has been subjected to considerable criticism at one time or another, and now that motorists have had a fairly lengthy experience of it, the time seems opportune to ask whether they have found it in practice to show advantages over the ordinary type of valve. The atmospheric valve is certainly the simpler, while being cheaper to manufacture, and, be it mentioned, particularly favorable to efficient carburation; but, on the other hand, it opens after a certain definite pressure has been reached, and is slack in closing. It also possesses the objectionable propensity of sticking, and, moreover, depends on the perfect adjustment of the spring. In a multi-cylinder motor this adjustment of the spring should be identical in each cylinder, since if the tension of the spring prove insufficient the valve will obviously not close rapidly enough, thus permitting the gases to escape on the compression stroke. If, on the other hand, the tension of the spring be too great, it resists the inrush of mixture, and, consequently, impairs the power of the motor. So considerable is the effect of the tension on the spring that certain constructors have in the past profitably turned it to advantage for governing the engine. Moreover the inertia of the valve becomes more pronounced as the speed of the motor increases, to the detriment of the volume of the intake, whilst the metallic noise of the valve is particularly objectionable.

Let us now look into why the automatic valve lends itself particularly to efficient carburation. The valve leaves its seat as soon as the vacuum in the cylinder exceeds the tension of the spring; its lift is, consequently, sudden, permitting a considerable inrush of mixture, when after closing it repeats this operation several times in rapid succession during the suction stroke. The demand on the carburettor is, therefore, pulsative, or intermittent, but the speed of the mixture emitted from the carburettor is always relatively high. The mechanically operated valve, on the other hand, only permits of a more protracted intake of mixture, the flow of which is for the time continuous, and consequently the demands on the carburettor are more exhausting, rendering the question of satisfactory carburation far more difficult of solution.

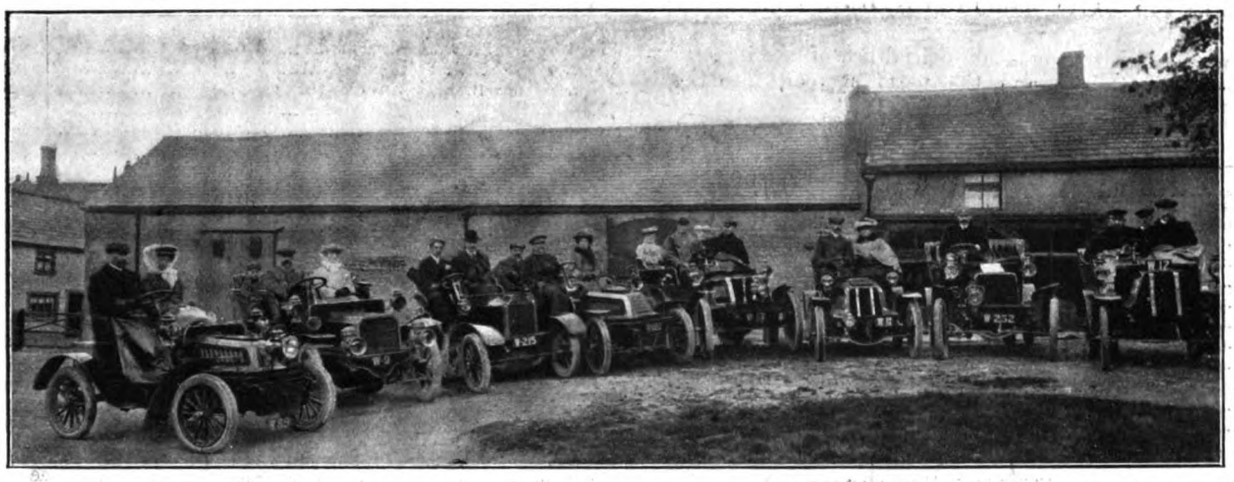
From the above it seems fair to infer that the mechanically operated valve is excellent in operation, provided its demands are satiated by a carburettor adapted to its peculiar needs; the power developed is directly proportionate to the speed of the motor; it is precise in operation, seeing that it opens and closes at the psychological moments; it can be made interchangeable with the exhaust valve; it does not stick; and the trivial mechanical complication which it entails (since it is merely a repetition of the construction necessary for the exhaust) is after all scarcely worthy of mention.—Yours truly,

NOGENTAIS.

STEAM CARS.

TO THE EDITOR OF *The Motor-Car Journal.*

SIR,—I have read with much interest the letter from "J. H." in your last issue, as I have what appears to be a similar car, and have had a very different experience to his. I have had, on a small tour in Devonshire, broken balls in the main engine bearing, water supply from boiler furred up, though the boiler was blown off every day or so, the water pump connection broken clean off, and for no apparent reason, the crank pin broken off, the piston seized, and finally the engine came completely away from the trunnions, and I finished up the journey with the engine resting on the brake rod. I write this letter in the hope that "J. H." may allow me to view his car, as I might get some useful information and so save these continual breakdowns.—Yours truly,



E. T. P.

MESSRS. J. W. BROOKE AND CO., Limited, are building a 15-20-h.p. four-cylinder car for Sir Saville Crossley.

THE Tramways Committee of the Wolverhampton Corporation are about to establish a motor-'bus service.

CLAIM AGAINST A MOTORIST.

A CASE was tried by Judge Emden at the Lambeth County Court recently arising out of a very serious accident which happened in Whitehall on the 25th July last. Mr. W. Glass, of Croydon, was driving his motor-car down Whitehall, when a collision took place between his motor-car and a hansom cab, the horse of which had its off fore leg broken and it had to be destroyed. Both parties claimed damages against the other for the injury done, but Mr. Glass was the first to commence proceedings, and the owner of the hansom cab entered a counterclaim for the sum of £50. Mr. Staplee Firth appeared for Mr. W. Glass, and Mr. A. Lincoln Reed for the owner of the hansom cab.

A large number of witnesses were called on behalf of the owner of the hansom cab, who stated that the motor-car was being driven at a furious speed and dashed in and out of the traffic, and also that it ran into the hansom cab. Mr. Glass' version, on the other hand, was that when passing the Horse Guards Parade at a moderate speed a hansom cab was driven out of a side turning and went into the side of his motor-car. This testimony was borne out by Mr. Lee, who was on the car with him, and one other witness. In the result, his Honour gave judgment for Mr. Glass upon his claim against the owner of the hansom cab, and also dismissed the counterclaim for damages for the loss of the horse, with costs.

DUST ABATEMENT.

THE SCOTTISH AUTOMOBILE CLUB (Western Section), recently undertook some oiling experiments with a view to dust prevention. Following a paper read before the Club on February 1st last by Mr. Robert Drummond, C.E., F.S.A. (Scot.), Road Surveyor to the County of Renfrew, the permission of the First, or Upper, District Committee of the Renfrewshire County Council was obtained to the experiments being conducted on their roads at Anniesland and Giffnock by the Club. These were carried out under the sight and to the satisfaction of the County Road Surveyors. Mr. Drummond was associated with the Club Committee in the matter, and, in addition to the visits from time to time of members of the Committee, has made special observations for the past three months on the results of the test, which form the conclusions in this report.

Experiments with Westrumite were made on the Anniesland road at Scotstounhill, and on the Kilmarnock road near Giffnock. Half a ton of Westrumite was used in each case, and at each place about half a mile of road was treated. These stretches of road comprise metalling at three stages of wear. Previous to the first application the road was thoroughly cleaned and swept, and a ten per cent. solution applied by means of ordinary watering-carts. Three days thereafter another ten per cent. solution was applied, but within a very few hours of this second application torrential rain fell over the district, which washed away a considerable portion of the mixture. Consequently, a third ten per cent. mixture was applied instead of, as was originally intended, two successive applications of five per cent.

Crude oil, supplied by the Glengarnock Chemical Company, Limited, was applied over a stretch of road comprising metalling at two stages of wear. In these cases the road surface was swept clean, and the oil poured on by means of cans, and brushed over so as to saturate the surface uniformly. In about twelve hours thereafter the road surface was dry enough to take the traffic, and not a single complaint of damage done to the paint of any vehicle thereby has been made. These experiments, comprising nearly one and a half miles of roads of fair average width, cost the club £30 8s. 11d., or an approximate cost of £20 per mile, which may be accepted as a fair average cost of this method of road dressing. The cost would necessarily be varied by differences in width of road. The various applications took place between 31st May and 23rd June last.

In the case of Westrumite, for a very considerable time after the application there was absolutely no dust raised by vehicles of any description passing over the road, and even yet, three months after the application, there is none to speak of, while the fact of the application having taken place over metalling of various stages of wear has demonstrated that on the older portions the tendency to dust is greater, as it is there that it has begun to show most.

On the Kilmarnock road the surface became glazed and somewhat slippery, and some complaints were made regarding this. On the Anniesland road there was not the slightest tendency to this whatever. Mr. Drummond states that in his opinion the hard metal used on the Anniesland road is more suitable than that used on the Kilmarnock road. He also observes that specially good results were got on newly metalled surface where the material taken from the old surface was used for binding, and that this observation is applicable to the results from both of the oils experimented with.

In the case of the crude oil the results obtained from the different stages of wear of road surface are not so noticeable. This material is most effective, but for the first week or ten days after its application, especially if wet weather prevails, it is not so clean as the Westrumite; neither is it so easily applied, nor so clean to handle. There is one point in its favour, viz., that one application suffices for a season. With the Westrumite several applications are necessary, at intervals varying according to the nature of the weather and the condition of the road.

The experiments have been so far successful, and have demonstrated the efficiency of the materials used for the purposes of dust prevention. For long stretches of road in the country the cost of the application might make its general use prohibitive, but in villages or populous places, or residential districts, the complete absence of dust in dry weather would be appreciated, and would be well worth an expenditure at the rate indicated above.

CASES AGAINST MOTORISTS.

Place.	Summoned for	Fine.

CLUBS AND ASSOCIATIONS.

HULL.

IT was decided to close the season's fixture list of the Hull and District Automobile Club by having a non-stop run to York and back to Hull on Thursday of last week. Twelve competitors faced the time-keeper at noon. Tool bags having been sealed up, a start was made for York, which was reached by Mr. Nicholson at 2.5. The others followed in quick succession. York was left at 3.5 and Hull reached at 5.10, Mr. Nicholson being again the first to arrive.

The winners of prizes are Messrs. Nicholson, Freeman, Hugestadt and Philipson. Messrs. Parker, Dunn, Lowery, Straker, Hamlyn, Hancock, Donovan, and Whiteley also took part in the event.

Dr. W. H. Coates, Chairman of the Executive Committee, acted as timekeeper at Hull, the Hon. Sec., Mr. G. M. Heard, at York, Messrs. Kemp and Donoworth as observers on the road, and Messrs. Entwistle, Strong and Strong, jun., took charge of control stations. After the event a dinner was held at the headquarters of the club, the Imperial Hotel, Dr. W. H. Coates presiding.

LEICESTERSHIRE.

THE results of the hill-climbing tests in connection with the Leicestershire Automobile Club held at Ab Kettleby were as follow:—

Mr. J. M. Bennett, 12-h.p. Darracq, 5 mins. 10 secs.
Mr. A. H. Faulkner, 10-h.p. Gladiator, 5 mins. 34 secs.
Mr. S. R. Brooks, 24-h.p. Richard-Brasier, 2 mins. 26 2-5 secs.
Mr. T. Peberdy, 8-h.p. Peberdy and Earp, 6 mins. 17 3-5 secs.
Mr. T. Corcoran, 5-h.p. Locomobile, 5 mins. 43 4-5 secs.
Mr. H. R. Harding, 8-h.p. Parr, 7 mins. 4 1-5 secs.
Mr. J. H. Wait, 10-h.p. Clyde, 4 mins. 7 secs.
Mr. A. McAlpin, 8 h.p. Parr, 6 mins. 7 secs.
Mr. T. C. King, 16-h.p. King, 4 mins. 34 secs.
Mr. J. Whitby, 5-h.p. Baby Peugeot, 6 mins. 43 2-5 secs.
Colonel L. L. Powell, 6-h.p. Argyll Voiturette, 7 mins. 45 2-5 secs.
Mr. R. S. Clifford, 12-h.p. Richard-Brasier, 5 mins. 31 2-5 secs.
Mr. H. E. Barron, 10-h.p. Peugeot, 5 mins. 13 2-5 secs.
Mr. E. G. Mawby, 15-h.p. Darracq, 3 mins. 10 2-5 secs.
Mr. H. Binns, 12-h.p. King, 4 mins. 44 secs.
Mr. E. H. Herbert, 6½-h.p. Cadillac, 7 mins. 41 secs.

In the tests of the two 5-h.p. Quadrant tricycles driven by Mr. J. H. Doran the trial with one passenger resulted in the time being given as 4 mins. 35 2-5 secs.; with two passengers the time was 5 mins. 19 4-5 secs.

FATAL MOTORING ACCIDENT.

AT the Bromley (Kent) Police-court, on Monday, Frederic Wilfred Baily was charged with the manslaughter of William Henry Norton, of Anerley. Mr. C. G. Lysett appeared for the accused and pleaded not guilty. Sub-divisional Inspector Sly said that on Sunday he made inquiries into a collision which occurred in Elmers End Road, Beckenham, on Sunday morning, between a motor-car driven by the accused and a bicycle ridden by Norton, by which the latter was killed. As a result of his inquiries he arrested Mr. Baily at his residence. The collision occurred at 12.40 p.m. and Mr. Norton died before three o'clock the same afternoon. On the application of the police a remand was granted for a week. Mr. Lysett asked for bail, and the Bench fixed it at accused in £100 and two sureties in £50 each.

The inquest on the body of William Norton was held at Penge on Tuesday. After an inquiry lasting five hours, during which much contradictory evidence was heard, the jury returned a verdict of "Death from Misadventure," and exonerated Mr. F. W. Baily from all blame.

POLICE TRAPS.

HARROGATE is becoming notorous among Yorkshire motorists by reason of police activity.

ON the London road, near Dunchurch, the police have a measured quarter of a mile.

THE

Motor-Car Journal.

VOL VI.] LONDON, SATURDAY, OCTOBER 22, 1904. [No. 294.

Published Weekly by CORDINGLEY & CO., 39 & 40, Shoe Lane, London, E.C.

COMMENTS.

THE following rules governing club competitions have been adopted by the Lincolnshire Automobile Club, and may be of service to other organisations arranging meets. Competitions shall be of two classes, private and open. All private club competitors shall be subject to the following rules, unless the committee shall specially alter the same. 1.—Cars may be entered by members of the L.A.C. only, must be registered as and be the *bona-fide* property of the member making such entry. Competing cars must be driven by the *bona-fide* owner or his servant. No car "for sale" or for hire shall be eligible to compete. 2.—Vehicles entered must be ordinary touring cars, and fitted with recognised touring bodies, and be solely used as private vehicles. The club committee shall be the sole judges as to what constitutes a touring body, or with respect to any other question raised in connection with the competition. 3.—The event shall be purely a club and sporting one, and competitors shall not use the results for advertising purposes. 4.—No certificates will be issued, and the committee will announce the results in such manner as they see fit. 5.—The committee will appoint judges, timekeepers, and stewards, and the decision of the judges in any dispute shall be final. 6.—The members of the committee present at any competition shall be a quorum to decide any question arising out of the competition, unless a special committee be appointed for the purpose of the competition. 7.—Open competitions shall be conducted under the rules issued from time to time by the A.C.G.B.I.

◆ ◆ ◆

Workmen and Motors.

WHILST bucolic Councils and rural wiseacres have been given to airing their views on the rapid speeds of motor-cars with considerable vehemence, only a few utterances from the working classes have found publicity in the Press, and it is rather remarkable to learn that the Preston Trades Council has been devoting some time to the question of the driving of automobiles through the cobble laid streets of that town. In fact, they have gone so far as to ask the Corporation to apply for a restriction order such as is now in force in the town of Beverley, and for which the Kingston, London and other authorities have made application.

◆ ◆ ◆

Racing on the East Coast.

THE Lincolnshire Automobile Club have under their consideration a scheme for holding a series of speed trials at Skegness next summer. The Earl of Scarborough has taken the initiative, and his agent has been in communication with Dr. F. H. Cragg, of Billingborough (the hon. secretary to the Club), respecting the project. Already the matter has been discussed by the Club committee, and two influential members—Sir Hickman Bacon, of Gainsborough (the president), and Mr. C. W. Pennell, J.P., of Lincoln—have been deputed to inspect the proposed course and report. It is understood that the residents of Skegness will do what they can to further the movement, and it is expected that a valuable silver cup will be offered for competition. The sands at this popular watering-place are said to be as fine and as smooth as any on the east coast, and are consequently admirably adapted for motor racing. If a meeting is arranged, as it most likely will be, the fixture will be one of the most important motoring events of next season.

◆ ◆ ◆

Obstructions on the Highway.

AT the last meeting of the Driffield Urban District Council, a letter was read from the secretary of the Hull and East Yorkshire Automobile Club pointing out that recently a member of the club, after dark, ran over a quantity of loose stones laid on the street at Driffield, and injured his machine, there being no warning lamp there at the time. The letter stated that should any further accident take place through the neglect of the Council to give warning of any danger on the road the club would take action to recover damages. The roadway, it was said, was under repair at the time, and an animated discussion took place on the whole method of road repair and the working of the steam roller, and ultimately it was agreed that in future red lamps should be placed in situations where there was any danger to traffic. This is a reasonable attitude to assume, for, if in addition to unlighted vehicles similarly unilluminated obstructions are to be allowed on the roadway the lives and limbs of all who use the highways after dark will be placed in jeopardy. We commend the action of the Hull Club and also of the Driffield Council, and trust it will be widely followed.

◆ ◆ ◆

Motor-'Buses in Surrey.

WE hear that many of the inhabitants of Surrey are signing a petition to the London and South Western Railway Company, asking them to establish a motor-omnibus service between Farnham and Hazlemere. Mr. St. John Broderick, M.P. for the division, is among the signatories, and there is no doubt that such a development would do much to revive prosperity in the intervening villages between these two places. It would be well if all Surrey motorists having any local acquaintance with or influence in the places named would use it in the direction of securing such a public boon from the railway company, for it could be secured without at all adversely affecting the railway traffic. In fact, it would act as a substantial feeder to the railway lines.

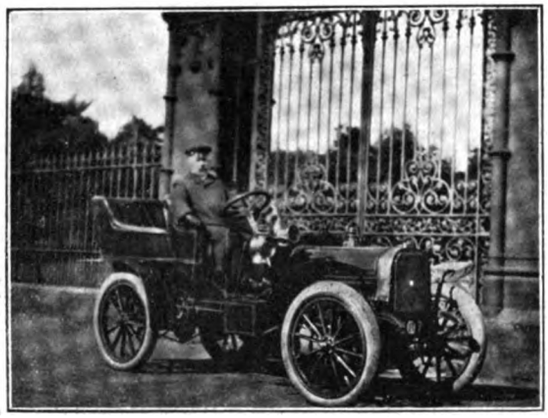
◆ ◆ ◆

A Speed Limit at Night.

THE Holland County Council of Lincolnshire, having made application for the closing of one road at night and for a speed limit of ten miles an hour at night for another road, the Local Government Board is to hold an inquiry. Both these roads run on embankments for about two and a half miles each. The one where the prohibition is asked for is the road from Deeping and Crowland, the other, where the speed limit comes in, is that from Spalding to Crowland, running on to Peterborough *via* Thorney. The embankments are very ancient, dating from the Roman invasion, and are used to hold the flood

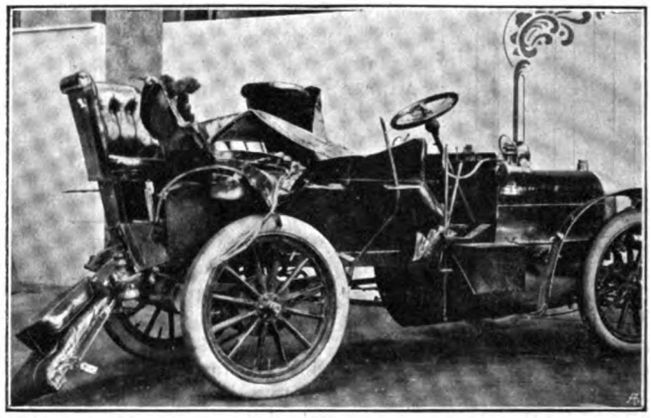
Digitized by Google

waters up. The former road is somewhat narrow in places, and there are gates across to keep the stock from straying, but the other road is on a lower bank and is as wide as any ordinary road. It is declared that if the present "Lights on Vehicles" bye-law in the county was amended, and all vehicles included, and the summer months not excluded, there would be no danger at night on these roads from vehicles (motors) that are better lighted than any other. The Lincolnshire Automobile Club has lodged an objection to the proposal.



◆ ◆ ◆

Traffic Accidents.



In our correspondence columns the Rev. H. George Morgan, an active member of the Herefordshire Automobile Club, draws attention to some official figures which have been published concerning the number of persons injured in traffic accidents in London during the last twelve months. From these it would appear that the proportion of accidents caused by horse-drawn and motor-propelled vehicles was 95½ and 3½ respectively. Seeing that as yet the great bulk of traffic in the metropolis is horse-drawn, it is very clear that the proportion of automobile accidents is extremely small, and even this is largely augmented by the mishaps occurring to motor-cars for which motorists can in no way be held responsible.

What is necessary.

Now that the unlighted cart has claimed a Royal victim, the Roads Improvement Association is pressing the following action upon the authorities:—(1.) That the Home Office should amend its model by-law so as to provide that all vehicles shall carry after dark a white light in front and a red light in the rear. (2.) That the Home Office in England and Wales, and the Secretary for Scotland in Scotland, bring pressure to bear upon the authorities to adopt the model by-law. (3.) That on the occasion of the passing through Parliament of a measure affecting local government a clause be inserted making it a statutory obligation for all vehicles to carry lamps after dark, so as to show a white light in the direction in which they are proceeding and a red light in the contrary direction—a provision, in short, similar to that which has already been enacted for motor-cars.

The 12-h.p. Argyll before the Collision.

The Car after the Accident.

THE ACCIDENT TO THE DUKE OF CONNAUGHT.

The Duke of Connaught's Accident.

The accident to the Duke of Connaught is a case in point. It is very clear that this was entirely due to the presence on the road of an unlighted cart. By a curious coincidence, only last week we drew attention to the seriousness of this matter, so far as Scotland is concerned, and in publishing the memorandum on Lights after Dark, prepared for the Scottish Club, showed how much improvements are desired north of the Tweed as well as in the southern country. Motor-cars are compelled to carry both front and rear lights, and it does seem a senseless anomaly that so many lumbersome vehicles should be allowed out after sunset without any lights to give warning of their approach. There is no doubt that the automobile has opened up a new series of problems for our legislators, and the sooner they deal with these points the safer will the road be for all users of the highway.

◆ ◆ ◆

England and Scotland.

In England and Wales it is within the powers of the county councils and the borough councils to make lighting by-laws subject to the sanction of the Home Office. In Scotland, a statutory enactment came into force in May of this year, affecting the boroughs but not the counties. The result is that in some counties in Great Britain horse-drawn vehicles must carry lights, and in others they are under no obligation to do so. Still more amazing is the fact that in certain counties which have adopted a lighting by-law, agricultural wagons and slow-moving carts—the most dangerous vehicles on the road—are exempt from its operation.

◆ ◆ ◆

Universal Lights.

The accident to the Duke of Connaught has aroused considerable sympathy with the Royal sufferer, whose enthusiasm for motoring has been most marked. Certainly he has done much to further automobilism, both in Society circles and in military matters, and all will wish him safely back to his public work. Until Parliament enacts uniformity in the provision of lights local motorists can perform a useful service to the community by impressing upon all owners of horse-drawn vehicles the advisability of providing lights for use after dark. Such things are necessary in the case of the motorist and the cyclist, and they should be equally compulsory with horse-drawn vehicles—especially those lumbersome lorries with projecting timbers—and other road dangers.

◆ ◆ ◆

Reports of Accidents Wanted.

Provincial clubs can render valuable help in the campaign for the compulsory lighting of all vehicles by maintaining local agitations. In Lincolnshire efforts have lately been made to secure the adoption of a by-law to insist on lights on all vehicles. These were not very successful, although we believe the county has agreed to have the present exemptions as regards seasonal lighting removed, and some uniformity secured

Digitized by Google

throughout the year. Such efforts must be generally adopted, and it would also assist the agitation if readers of the *Journal* would keep us informed of any accidents resulting from unlighted vehicles, so that the dangers of the present position may not escape public attention.

◆ ◆ ◆

Coroners and Cars.

A FEW months ago we recorded the view of a coroner in the county of Kent, to the effect that he had been somewhat surprised that he should have been called upon to attend no inquests on the bodies of persons killed in motor-car accidents. Now Dr. John Harrison, the coroner for north-east Essex, has given an even better testimonial to the motor-car. On Monday he held three inquests—not, be it noted, on automobile victims—in three different districts, necessitating a journey of over 100 miles in his motor-car. The first at Braintree, the second at Brightlingsea, and the third at Maldon. The cross-country journeys between the first and second places and the second and third, respectively, are each 26 miles, and railway communication is by no means so up-to-date as on most parts of the Great Eastern Railway system. The coroner was able to return to Braintree before evening, thus giving a practical demonstration of the value of the motor-car to those in official positions.

◆ ◆ ◆

Motor Vehicles in Agriculture.

AN important experiment was begun in the neighbourhood of York last week by the North-Eastern Railway Company with a view of testing the possibilities of a service of steam motor-lorries for the collection and distribution of heavy traffic in remote agricultural districts. The idea is that the lorries should serve the same purpose as that for which many light railways have been promoted. Should success attend the venture, it is proposed to extend the service to other parts of the system. A steam lorry of five tons burden, with a trailer having a carrying capacity of two and a half tons, will run between Tollerton Station, on the main line north, and the village of Brandsby, situate between Easingwold and Malton. On the outward journey it will carry limestone, feeding stuff, &c., for delivery at the various farms in the district, and the return journey will be made with produce to be forwarded by rail. Besides facilitating transport and putting the farmers in closer touch with the markets, it is expected that the service will prove a considerable saving to them in the matter of haulage.

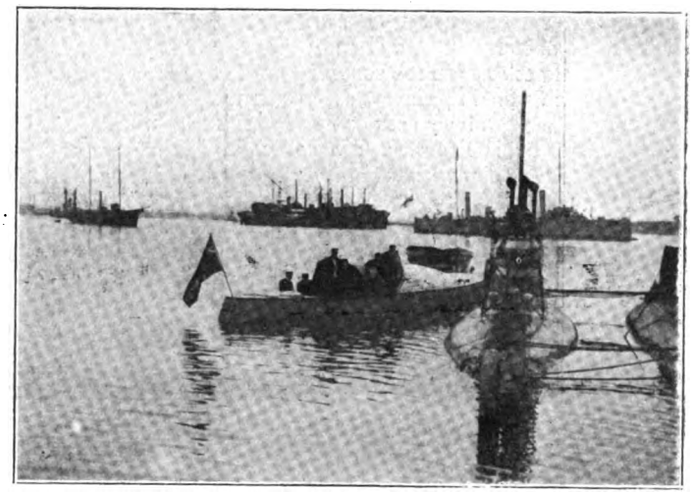
◆ ◆ ◆

Schoolboys and Motor-cars.

WE notice that at the meeting of the Huddersfield Centre of the Yorkshire Automobile Club quite a serious talk took place on the way in which local motorists have been subject to annoyance by small boys forming up into line in front of advancing cars, and also indulging in the old trick of throwing their caps beneath the wheel. The Huddersfield motorists came to the conclusion that the matter is becoming not only a nuisance, but a very serious hindrance to their progress in the town, and the secretary of the Centre has been instructed to write to the head masters of all the schools in the district, asking them to impress upon their scholars the dangers lurking in such a childish practice. Unfortunately, the British schoolboy is not always amenable to good advice; but, failing any more conclusive proposal, the course taken by the Hudderfield folks is, perhaps, the most impressive that can at present be adopted.

◆ ◆ ◆

Dustless Road Experiments at Wandsworth.



THE experimental paving with tar macadam at Wandsworth Common, between North Side and Trinity Road, is reported to be a success, so far as the question of cost is concerned. The sum of £667 was spent on laying the strip of road with the macadam, and the cost of maintenance, including scavenging, watering, and repairs for the year since it was put down, has been £42. The expense of scavenging, watering and repairs of a similar area of granite macadam in North Side for a year is £74, or £32 in excess of the tar macadam, and Mr. P. Dodd, the surveyor for the western district of Wandsworth, estimates that, taking the saving in scavenging into consideration, the cost of a tar macadam road in nine years would not exceed for the same period that of a granite road. The Highways Committee of the Borough Council have now given instructions for the testing of the patent paving known as "tar mac." This is to be used on the carriage-way in Huguenot Place, between the eastern side of Woodwell Road and the crossing at East Hill.

◆ ◆ ◆

The Use of the Dealer's Mark.

AT the meeting of the Cardiff Cabs' Committee, it has leaked out that some of the motor-car agents in the town are reported to have been in the habit of letting cars out on hire without the same being properly registered. We are afraid that lack of knowledge of the stringent provisions of the Motor Car Act is responsible for some errors of this kind in other places besides Cardiff, and it would be well for those in charge of garages and similar establishments of automobile resort to understand that the issue of the dealer's licence and mark only carries with it the right to use a motor-car, first for trial, or secondly to take out the intending purchaser, in order to test it. It is very clear, therefore, that the use of a car bearing a dealer's mark when a purchaser or a likely purchaser is not upon the vehicle is contrary to the spirit of the Act, and likely to lead the delinquent to the local police court.

The Motor Boat "Napier Minor" alongside one of the most recent British Submarines. A couple of Officers from the Submarine Department, who were trying her through various evolutions, are on board.

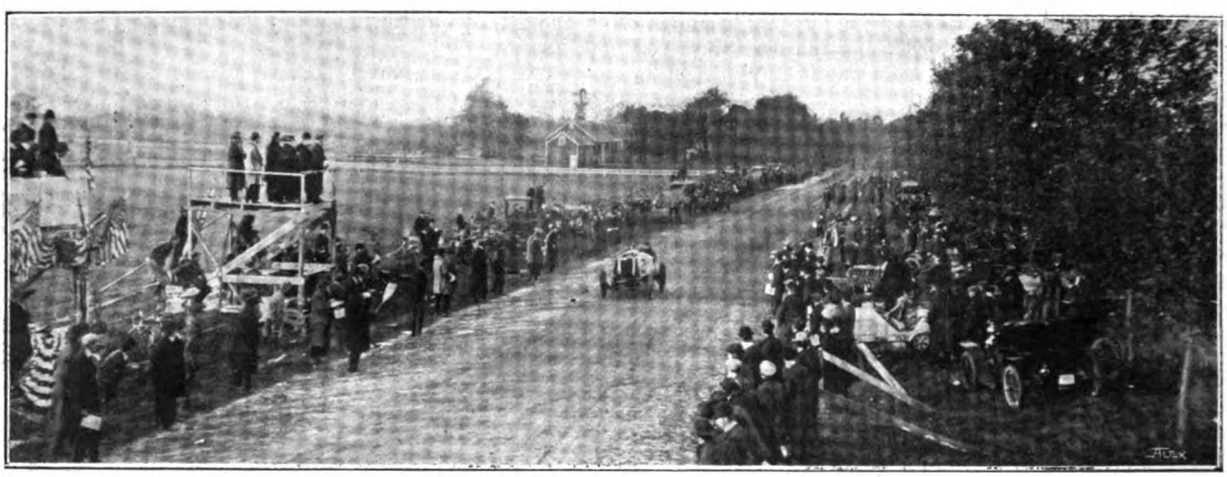
◆ ◆ ◆

Proposed Restrictions in Ayrshire.

A MEETING of Ayrshire motorists has been held in Ayr, to consider the proposal of the Ayrshire County Council to apply to the Secretary for Scotland for authority to close certain highways in the county to motor-car traffic, and to restrict the speed of motor-cars to ten miles an hour in towns and villages, and on bridges in the county. The meeting was called to oppose the County Council proposals. Commander Hunter-Blair, of Blairquhan presided. Mr. Smith, Secretary to the Scottish Automobile Club, made a statement as to the results of similar applications in other parts of Scotland. Sir James Bell said the County Council were the chosen representatives of the people of the county, and, of course, it was desirable that they should take every precaution to protect the public, but at the same time there was another side to the question, and he thought automobilists might with confidence place their view before the Council. If the county wished to take parental care of them, there were a great many bridges and bad turns on roads where they ought to put up danger notices, which would be

Digitized by Google

useful not only to motorists, but to users of the roads generally. He did not know on what basis the County Council had included all those bridges and villages; but it looked as if they had gone on the principle of asking a great deal in order to get a little more than they expected or were entitled to. He did not think at all that their application to the Secretary for Scotland would be granted to the extent they proposed; but he should wish the County Council to feel that they as motorists were wishful to help in conserving the safety of the public, while they were also as firm, as users of the public road, to get all they were entitled to. He thought the Motor Car Act was as drastic as it could be, and the County Council ought to know that motorists thought the Act was stringent enough, and that further restrictions were unnecessary. After some further discussion the meeting unanimously resolved to represent to the Secretary for Scotland their disapproval of the application of the County Council for the prohibition of motor-car traffic on certain roads and the further restriction of the speed of motor-cars.



◆ ▼ ▲

Duty-free Alcohol.

AT a meeting of the Council of the Birmingham Chamber of Commerce the General Purposes Committee have recently presented a report dealing with the use of duty-free spirit for industrial purposes. The question is of great importance to many industries carried on in Birmingham and district, and the committee thought that steps should be taken to collect evidence to be placed before the committee. Complaint had been made to the Committee as to the utter inadequacy of Section 8 of the Finance Act, 1902, owing to the excessive restrictions sought to be imposed by the Inland Revenue Commissioners, and, even when those were partially removed, to the very small quantity of spirit which manufacturers were allowed to use duty free. In other words, the section referred to was rendered almost inoperative. It had been pointed out to the committee that in other countries, Germany for instance, manufacturers were given every facility for the use of commercial spirit duty free, and that that placed the foreign manufacturer in a superior position to the English. With the view of obtaining information to place before the committee which had been appointed, the committee recommended that a circular be addressed to manufacturers and users of spirit for industrial purposes, asking them to reply to certain questions. The Chairman, in moving the adoption of the report, stated that several representations had been made to the Chamber, and he understood that pure spirit could be made for 9d. per gallon. On proof spirit, the potable drink, the duty was 15s. a gallon, but for industrial purposes the spirit was required to be 64 over proof. In Germany there was a duty on potable spirits, but the Inland Revenue Department of that country knew how to deal with it so as not to interfere with industrial progress.

Petrol v. Alcohol.

A CORRESPONDENCE having arisen with regard to the comparative merits of alcohol and petrol for automobiles, Messrs. J. Crossfield and Sons, Limited, who have made a special study of the matter, point out that it is true that petrol contains more available heat energy than alcohol, but they say that the efficiency of the alcohol engine is higher than that of the petrol engine, the result being that volume for volume petrol is about one-eighth more efficient than 90 per cent. denatured alcohol containing only 2 per cent. of benzine. Having regard to the fact that the alcohol thus compared contains 10 per cent. of water, the difference in this respect is so small as not to be worth very serious discussion. Up to quite recently a water-white alcohol of about 97 per cent. strength could be bought at about 9d. per gallon in Germany. Possibly in the course of the last few weeks, owing to the very grave shortage of the potato crop, this price may have risen somewhat. The actual price paid by motor-car owners in Germany for denatured alcohol suitable for their purpose is about 9d. per gallon delivered at the nearest railway station, and at this price it is obvious that alcohol can compete with petrol at 10d. It is not significant that none of the recent Gordon Bennett cars were run on alcohol. The machinery for the distribution of alcohol is by no means so efficient as that for the distribution of petrol, nor is the former fuel yet obtainable in many of the countries where petrol can be had, and consequently there is not any temptation for automobile builders to design engines specially fitted to run on this, as yet, comparatively seldom-used fuel. It is only by greatly extending the utilisation of alcohol that it will pay to manufacture it in a form fitted for industrial purposes. It can be proved that the home-manufactured product is practically equal to the imported one as a power producer, and that, in addition, the possibility of utilising cheap alcohol in other industrial directions would mean the starting of new industries and the encouragement of old ones.

The Scene at the Start of the Vanderbilt Cup Race.

A RACE between one of the Calais-Dover mail steamers and a powerful motor-boat is, we hear, on the *tapis*.

LAST week we gave the route of the two Oldsmobiles on tour in Ireland. The cars reached Cork on the 13th inst. As there was no boat leaving Cork on Thursday, the cars were shipped on Friday night, arrived at Milford Haven Saturday morning, reaching Cardiff Saturday evening, and on Monday of this week commenced the following route:—Cardiff to Gloucester; Tuesday, Gloucester to Taunton; Wednesday, Taunton to Bodmin; Thursday, Bodmin to Truro; Friday, Truro to Exeter; to-day (Saturday), Exeter to Bath. While at Cork the 7-h.p. car climbed the steep St. Patrick's Hill, which has only been ascended on one or two occasions by an automobile.

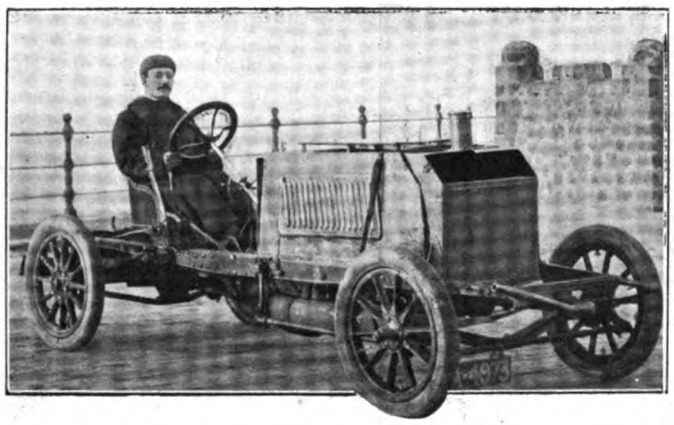
The Blackpool Speed Trials.

THE Blackpool motor meet is now an event of the past, and must be written down as a brilliant success. The arrival of motorists commenced early in the week, and by Thursday the toot-toot of motor-horns was to be heard at every corner of the popular resort. Local residents were not long in discovering that some fine sport was to be seen in the early morning, the competitors taking full advantage of the permission to use the course for trial spins between the hours of 6 a.m. and 8 a.m. Not only were the big racers being exercised; touring cars of all classes, and fully laden, were vieing with one another in twos and threes. Indeed, the spectacle presented was considered by many to be far more exciting than the races proper, in that the cars followed at intervals of seconds in place of minutes, several teams being always in view simultaneously. All the week the Corporation officials were busily engaged in preparing the course and erecting a grand stand at the finishing point. The whole of the promenade, from the commencement at the South Shore to the Central Pier, a distance of about a mile and a quarter, was barricaded off to form what is undoubtedly the finest racing track in the country. The course has a slight curve in it at about 300 yards from the start, but it is not sufficient to prevent top speed being maintained all the way. Not only so, but the surface is ideal, consisting as it does of newly-laid asphalt. It is wide enough, moreover, to enable two cars to race abreast with perfect safety, while several motor-bicycles can compete at one time. Beyond the finishing point a long line of tramcars was drawn up, and served to form a huge stand. Several of the hotels and boarding houses on the course had also put up stands, and although Friday was cold and the morning's crowd not very thick, in the afternoon every seat was occupied, and the barricades were lined with a crowd estimated at from 40,000 to 50,000.

Photo by] A Group of Officials on the Finishing Line. [*R. W. Lord.*

The Blackpool councillors postponed municipal business because it was the day of the motor trials, and tradesmen closed their shops in the afternoon for the sufficient reason that there were no signs of customers in any of the streets. The piers were empty, and those people on "the front" walked only in one direction—towards South Shore. Policemen were stationed at every few yards on the course, and the Blackpool Nursing Association sent out several squads of ambulance men with the necessary equipment, who took up positions at different points in case of accident, but fortunately their services were not required. Except in the case of the racers, the competitors, of whom there were altogether about 120, were not allowed to return to the starting point along the track, but had to make their way back along a somewhat bumpy road behind the promenade.



Shortly after 10 a.m. the competitors in Class A were ordered to get ready. Fourteen entries had been received for the event, which was confined to motor cycles weighing not more than 170 lbs., but only eight faced the starter. These were sent off in two batches of four. In the first heat the competitors were:—E. T. Jones (Humber), O. L. Bickford (5-h.p. Chase), B. Blaker (Bat), and H. G. Metcalf (3-h.p. Bradbury). The race was hotly contested, Jones being first in 1 min. 24 1-5 sec. and Bickford second in 1 min. 26 2-5 sec. Heat 2 brought out H. Rignold on the 4½-h.p. Lagonda he rode in the recent international race in France, Holgkinson on a 4½-h.p. Jap, T. H. Tessier (4½-h.p. Bat) and J. F. Crundall (Humber). Tessier quickly got away and set a very fast pace, winning easily in 1 min. 19 2-5 sec., Crundall being second in 1 min. 22 2-5 sec. The final heat brought out Jones, Bickford, Tessier and Crundall. The pace was again

Mr. Andrew Fletcher starting for the Flying Kilometre on his 90-h.p. Mercedes.

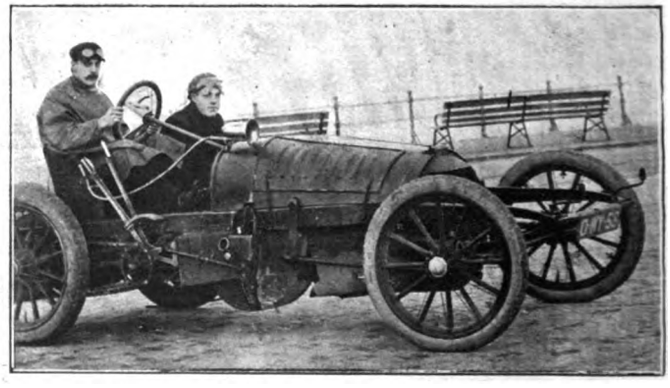
fast and Bickford was quickly outdistanced and left in the rear, Tessier coming in first in 1 min. 13 2-5 sec., equal to a speed of over forty-nine miles per hour; Crundall being second in 1 min. 18 sec. Class B, for motor-cycles, unrestricted as to weight, proved another exciting event, the five competitors—Jones, Rignold, Hodgkinson, Tessier, and Crundall—being sent off in one bunch. Tessier's machine again showed its superiority, he covering the standing mile in 1 min. 15 sec., beating Crundall (second) by 1 4-5 sec.

Mr. Clifford Earp on the 80-h.p. Napier.

Class C, for cars to carry not less than two passengers and costing £250 or under, was run off in a series of heats followed by demi-semi finals, semi-finals and finals. There were altogether thirteen entries, including a 7-h.p. Star, a 10-h.p. Vulcan, a Ribble voiturette, a 10-h.p. Speedwell, an 8-h.p. Rover, an 8½-h.p. Cadillac, a 9-h.p. Norfolk, a 6-h.p. De Dion, a 10-h.p. Vulcan, a 10 h.p. Duryea, a 10-h.p. Nelson, an 8-h.p. Eagle and an 8-10 h.p. Brown, the latter being driven by Miss M. Hind. The race for the final between the 10-h.p. Speedwell driven by Mr. J. W. H. Dew and Mr. E. Failes Baker's 10 h.p. Duryea resulted in a victory for the latter in 1 min. 49 2-5 sec. A protest was, however, entered with regard to the vehicle not being eligible for the under £250 class, and at a meeting of the organising committee held in the evening the protest was upheld, the first prize being awarded to Mr. Dew.



After a short interval for lunch the races were recommenced in the presence of a much larger crowd than in the morning. Class D, for cars to carry not less than four passengers, and costing up to £500, brought out seventeen competitors. The event was run off in heats, the majority of which were rather tame, owing to the distance which separated the two cars the greater part of the mile. The tightest run, which, although far from being the fastest, created the greatest interest on the part of the spectators, was between the Elsworth Company's 14-h.p. Spyker and Mr. P. C. Kidner's 12-14-h.p. Vauxhall—a new three-cylinder car—the two vehicles finishing almost neck and neck, to use a horsey term. The fastest time (1 min. 31 2-5 sec.) was made in the semi-final, in which three 15-h.p. Darracqs competed. The final was a struggle between Mr. F. C. Noar and Mr. J. Keele, the former winning in 1 min. 36 3-5 sec.

Class E.—For cars to carry not less than four passengers and cost up to £750, brought out thirteen competitors. The fastest race in the heats was between a 20 h.p. Pipe driven by M. Dumont, and a 16-18-h.p. Sunbeam (time 1 min. 14 sec.). The Pipe successfully went through the demi-semi and semi-finals, but was beaten in the final by Mr. Huntley Walker's 30-h.p. Darracq, which covered the mile in 1 min. 34 sec.

There were eleven entries for class F, for cars to carry not less than four passengers and costing up to £1,000, all of whom lined up at the start. They were dispatched in pairs, the fastest heat being that in which Mr. J. W. H. Dew's 24-28-h.p. Bollée was beaten by Mr. P. Martin's 30-h.p. Daimler; time 1 min. 9 2-5 sec. The race between the 18-22-h.p. Mercedes driven by Mr. H. A. Whalley, and Miss Dorothy Levitt on a 20-h.p. Napier proved a popular victory for the latter, her time being 1 min. 30 3-5 sec. Mr. P. Martin, who had qualified for the final, was unable to compete owing to the water circulating pump of his Daimler being damaged, and the race was a struggle between Miss Levitt and a 40-h.p. Leon Bollée driven by Mr. H. Martin, the latter winning by about twenty yards in 1 min. 21 3-5 sec.

Very few of the races being keenly contested, the victors winning easily, the interest of spectators had somewhat flagged, but when class G, for cars to carry four passengers, irrespective of cost, was reached, a buzz of excitement went along the course. The competing cars included no less than five 60-h.p. Mercedes, a 60-h.p. Fiat, a 40-h.p. C.G.V., a 36-h.p. Spyker, a 40-h.p. Mercedes, a 40-45-h.p. Leon Bollée, and a 25-h.p. Rochet-Schneider. Mr. Cecil Edge's 65-h.p. Napier did not compete, owing to a successful protest that the vehicle was not a touring car according to the rules of the meeting. The fastest race in the first round was that between Mr. C. Cordingley's 60-h.p. Mercedes and Mr. L. Williamson's car of similar make and power, the latter winning by a few yards in 1 min. 9 sec. Considerable interest was shown in the race between the 60-h.p. Mercedes of Mr. Huntley Walker and Miss D. Hampson, owing to this lady driving her own car. She was, however, out-distanced, on account of the gear box on her car going wrong. The competitors in the final were Mr. A. J. Dew on a 40-h.p. Bollée, and Mr. L. Williamson, 60-h.p. Mercedes, the latter winning easily in 1 min. 15 sec.

The *bonne bouche* of the day was reserved to the last, and, although the crowd had somewhat thinned as darkness came on, those who stayed to the end were provided with a brilliant display of speed by the cars which competed in Class L—Racing cars weighing less than 1,000 kilogs. The cars were again dispatched in pairs, a 96-h.p. Wolseley driven by Mr. A. Callan and a 100-h.p. Darracq driven by Mr. A. L. Guinness being sent off first. This was the car which, as mentioned in the last issue of the *Journal*, was fitted with a new form of ignition, and many of the motoring spectators were looking forward to its performance with especial interest. They were, however, doomed to disappointment, for just after leaving the starting point the case surrounding the differential on the back axle gave way and Mr. Guinness was forced to abandon, Callan finishing alone in 1 min. 2 1-5 sec., equal to 58 miles per hour. In the next heat, Mr. G. Higginbotham on a 96-h.p. Wolseley made the fastest time of the day—56 sec., or equal to 64·28 miles per hour—beating Mr. A. Rawlinson on a 100-h.p. Darracq. In the contest between the Hon. C. S. Rolls on a 100-h.p. Mors and Mr. A. Fletcher on a 90-h.p. Mercedes

Mr. G. Higginbotham on the 96-h.p. Wolseley.

the latter won in 57·4 sec. In the semi-final, Mr. A. Fletcher was beaten by Mr. Higginbotham, Mr. Callan having a walk-over. The final was a keen struggle between the two 96-h.p. Wolseleys, that driven by Mr. Higginbotham proving itself the winner, the standing mile being covered in 58 3-5 sec., or a speed of 61·43 miles per hour.

No accidents or hitches marred the day's proceedings. In the races for touring cars the finishes were sometimes tame,

Digitized by Google

because any slight difference in speed capacity at the start became considerably accentuated before the finish, and runaway wins were frequent. When the finishes were close, however, the crowd cheered enthusiastically, and, on the other hand, indulged in good-humoured chaff when one car struggled in a long way behind its rival. Much amusement was repeatedly evoked, moreover, by the intermittent appearances of dogs upon the track. The results were signalled in a novel but effective manner. Of each pair of competitors one driver wore a blue band and the other a white one, and after the finishing line was crossed a white or blue flag was hoisted, according to the colour worn by the winner. Similar flags at intervals along the course passed the result along right up to the starting point.

The Second Day.

On Saturday morning the motorists were early astir, practising over the course with the view of getting their vehicles *au point* ready for the contests. While Friday was somewhat dull and cloudy, Saturday was gloriously fine, and it was consequently not surprising that the promise of some fine racing over the flying kilometre, over which all the races except the matches and the Darracq and Clipper cup events were run, brought together an unusually large yet orderly crowd to the promenade. Not only did the local residents turn out, but train after train brought in interested visitors from the many industrial centres in Lancashire. In the afternoon the course was thickly lined on both sides from end to end, the grand stand was packed, and the twenty tramcars, which had been poorly favoured on the preceding day, each had its full quota of spectators. The sight was a pleasurable one to the Blackpool authorities, who, accustomed as they are to thousands of visitors in the summer, have never before seen so many people in their midst in the month of October. Various estimates were made as to the number of people who witnessed the race, the general opinion being that there were not less than between 50,000 and 60,000 spectators.

As there was a big programme to get through, it was decided to make an early start, and shortly after 9.30 a.m. the competitors in Class Q—motor-cycles weighing under 170 lbs.—were marshalled up. There were in all nine riders, an addition to the previous day's list being Mr. Binks on a Binks four-cylinerd machine, which, however, did not show any great speed. T. H. Tessier on his 4½-h.p. Bat again proved invincible, his time for the flying kilometre being 36 3-5 sec., equal to 61·6 miles per hour. J. F. Crundall (Humber) was second in 39 4-5 sec., and H. Rignold (4½-h.p. Lagonda) third in 41 sec. Class R, for motor-cycles of any weight, brought out a field of six riders, Tessier again proving the victor and improving his time to 35 3-5 sec., with Crundall second in 39 2-5 sec., and E. T. Jones (Humber) third in 42 sec.

Attention was next given to Class S, for cars to carry not less than two passengers and costing £250 and under. Altogether ten vehicles competed, the best time being made by Mr. A. J. Dew on a 10-h.p. Speedwell, who covered the flying kilometre in 1 min. 2 1-5 sec., equal to about thirty-six miles per hour. The second place was secured by Mr. J. S. Bennett on an 8½-h.p. Cadillac in 1 min. 3 4-5 sec. Mr. J. Lisle on a 7-h.p. Star being third in 1 min. 9 sec. The slowest car in this class covered the flying kilometre at a rate of 27 miles per hour, so that it may be said that the various vehicles costing under £250 acquitted themselves well from a speed point of view.

No less than 19 competitors turned out in Class T—car to carry four passengers and costing under £500. There was, however, considerable variation in the speed attained, the times for the kilometre varying from 48 1-5 sec. to 1 min. 9 4-5 sec. Several close finishes served to arouse the interest of the spectators, notably a race between a 12-h.p. Pipe and a 12-h.p. Star, only 3-5 sec. separating the two at the finish. In the end, the event resulted in a victory for Mr. J. R. Richmond's 15-h.p. Darracq, time 48 1-5 sec., or about 46 miles per hour, Mr. J. Keele being second on a similar car in 51 4-5 sec., and Mr. W. J. Duck third on a 20-h.p. Weston in 54 1-5 sec. The next event was a competition between the four types of Darracq cars, 12-h.p., 15-h.p., 24-h.p., and 30-h.p., for a 100 guinea challenge cup presented by the Darracq Company to be run off annually over a mile course from a standing start, the cup to become the absolute property of any person winning it three years in succession. The cup was run for in classes according to horse power, the winners of each

Mr. A. Rawlinson on the 100-h.p. Darracq Racer.

Digitized by Google

class being handicapped together, and running off in a final. In addition to the challenge cup, the Darracq Company also presented a cup value £10 to the winner, and cups to the value of £5 each to the winners of the other classes. Altogether four 12-h.p., six 15-h.p., and two 30-h.p. cars competed. Mr. H. Kennedy's 12-h.p. vehicle won in 1 min. 43 sec.; Mr. Huntley Walker's 30-h.p. car was second, 1 min. 49 2-5 sec.; and Mr. F. C. Noar's 15-h.p. third.

Interlarded between the programme events was a series of matches, which added much to the enjoyment of the spectators, owing to the exciting finishes. The first one was between Mr. Charles Cordingley's 60-h.p. Mercedes and Mr. W. D. Coddington's 12-h.p. Lanchester over the flying kilometre, the former allowing the latter 1 min. start. It was too big a handicap for the distance, and the Mercedes was beaten by forty yards, the time being 1 min. 9 2-5 sec., as against 36 sec. by the Mercedes. Mr. Cordingley also made a match over the standing mile against Mr. Andrew Fletcher's 60-h.p. Mercedes, which he beat by 8 sec., doing 1 min. 7 2-5 sec., 53½ miles an hour, thus winning the "Andrew Fletcher Cup." In a race between Mr. Miller's 60-h.p. Fiat and Mr. Cordingley's 60-h.p. Mercedes, the latter was again successful. The concluding match was for £50 a side between Mr. F. Birtwistle's 24-h.p. De Dietrich and Mr. E. Instone's 28-h.p. Daimler. The Daimler won by 100 yards, covering the flying kilometre in 43 4-5 sec., against the De Dietrich's 55 3-5 sec.

After an adjournment for lunch, the bugler called up the fourteen competitors in Class V—cars carrying four passengers, and costing under £750, the result being shown below:—

No.	Name.	Car.	Time. m. s.
10	A. J. Clay	20-h.p. Rykniel... ...	1 0 4-5
11	S. F. Heyl-Dia ...	20-h.p. Newton Pearce...	1 1 2-5
12	P. A. Bell	24-h.p. Bell	1 1 4-5
13	W. D. Coddington ...	12-h.p. Lanchester ...	1 5 1-5
14	C. E. Oliver	15-h.p. C.G.V.	1 12 1-5

Some excellent racing was witnessed in Class W—cars carrying four passengers and costing under £1,200. There were altogether ten competitors, the times ranging from 40 3-5 sec. to 54 3-5 sec. The first place was taken by a 40-h.p. Leon Bollee in 40 3-5 sec., Miss Levitt on a 20-h.p. Napier being second in 42 1-5 sec., and Mr. S. Ormerod's 19-h.p. Mors third in 44 3-5 sec. With the advent of Class X—for four-seated cars, irrespective of cost—the crowd settled down to its long-awaited display of fast travelling. Nor were they disappointed. The competitors included three 60-h.p. Mercedes, a 40-h.p. C.G.V., a 45-h p. and a 24-28-h.p. Leon Bollèe and a 36-h.p. Spyker. Mr. L. Williamson proved to be the winner, he covering the flying kilometre on his 60-h.p. Mercedes in 33 2-5 sec., beating Mr. Cordingley's car of the same make and power by exactly a second, the latter being classed second. The third place was secured by the Elsworth Co.'s 36-h.p. Spyker, the time 38 3-5 sec.

The special contest for a cup presented by the Clipper Tyre Company was next held. This was a standing mile handicap contest between touring cars of 20-h.p. and upwards, the competition being open to p.ivate owners only, who had to drive their cars themselves. Mr. L. Williamson (60-h.p. Mercedes) was on scratch, Mr. A. Fletcher (60-h.p. Mercedes) having five seconds, Mr. F. Birtwistle (24-h.p. Dietrich) 15 seconds, and Mr. T. Thornycroft 30 seconds. The handicap allowances were given in despatching the cars, the first past the post winning. In the first round Mr. F. Birtwistle did 1 min. 55 sec., Mr. L. Williamson 1 min. 9 3-5 sec., Mr. Thornycroft 1 min. 34 3-5 sec., and Mr. A. Fletcher 1 min. 12 4-5 sec. In the final Mr. Thornycroft won by a yard from Mr. Williamson in 1 min. 33 1-5 sec., the loser's time being 1 min. 4 1-5 sec. The two cars crossed the tape almost together, amid great excitement, as the Mercedes was gaining ground very rapidly, and if the course had been but a yard or so longer Mr. Williamson would have undoubtedly won. The excitement was increased by the fact that just as the two cars had crossed the finishing line practically side by side, a big dog ran on to the track, right into Mr. Williamson's car. It was instantly killed; fortunately the car was not deflected from its course, otherwise the consequences would have been most serious, a collision being almost inevitable.

The last item on the programme had now been reached, and the crowd prepared to thoroughly enjoy the exhibition of speed in store for them. A crackling as of artillery fire gave warning that the fast racing machines were making their way to the starting point. They carried no horns to warn people to make way for them; the banging of the exhaust was in itself an alarm that made stragglers in the roadway bound to the pavement. The cars were run singly, and Mr. A. Rawlinson's 100-h.p. Darracq, the most sensational racer of the group on account of the terrific noise it made, took the opening spin over the course. Its speed was 82·49 miles. Then came Mr. Clifford Earp, driving an 80-h.p. Napier, he making the best time of the day, covering the flying kilometre in 26 2-5 sec. His speed works out at 84·68 miles per hour, which ties with that achieved by the Hon. C. S. Rolls at Welbeck, on a course which has a much slower surface than that at Blackpool, but is slightly downhill. Most of the cars made several trips over the course, Mr. Rawlinson, Mr. Rolls, and Mr. Earp in particular striving to beat the British record, which the latter had tied. Mr. Rolls' Mors, the same car as made record at Welbeck, ran very badly in its first two attempts, and then suddenly improved, he succeeding in covering the course in 26 3-5 sec., or only a second slower than Mr. Earp. The following are the performances:—

Driver.	Car.	M.p.h.	M.p.h.	M.p.h.	M.p.h.
C. Earp ...	80-h.p. Napier ...	84·68	82·80	80·42	81·58
A. Fletcher ...	90-h.p. Mercedes ...	79·27	69	—	—
A. Callan ...	96.-h.p. Wolseley ...	67·74	61·43	63·51	—
G. Higginbotham	96-h.p. Wolseley ...	76·55	—	—	—
A. Rawlinson...	100-h.p. Darracq ...	82·49	80·42	82·80	79·27
C. S. Rolls ...	100-h.p. Mors ...	46·57	54·26	84·04	78·16

A rush was then made for the grand stand, where the Mayoress, Mrs. G. Blundell, distributed the handsome cups to the winners of the various events, and thus ended what had undoubtedly proved the most successful motor meet so far held in this country, either from the point of view of the number of entries, the public interest, or the speeds attained. Although one or two points could be improved upon, especially as regards the telephonic time-keeping arrangements, which got somewhat deranged on the second day, Mr. G. H. Woods, the hon. secretary, Mr. Huntley Walker and the other members of the Committee deserve warm commendation upon the success of their first meeting. Beyond the killing of a dog, and a slight collision between two of the cars, the two days' meet passed off entirely without accident. It remains to be added that Colonel Holden and Mr. Mervyn O'Gorman acted as judges; the times were taken by Messrs. J. H. Woollen, A. V. Ebblewight, F. Straight, and J. H. Swindley. The cars were marshalled at the starting point by Sir Archibald Macdonald and Mr. Charles Jarrott, Mr. E. Shrapnell Smith being the starter. The Blackpool Corporation spared no pains to make the meeting a success, and are already contemplating holding another meet next year.

WHEN leaving the car at night, or for any length of time, make it a practice to shut off the petrol supply. If this is not done, and if there is a leak, or a flooded carburettor, a fire may be caused by someone carelessly tossing a burning match under the car.

CONTINENTAL NOTES.

The Chateau-Thierry Hill Climb.

The annual hill-climbing competition, to be run off at Chateau-Thierry on Sunday next, is this year being restricted to touring vehicles. So far only about thirty-five entries have been received, the leading firms being conspicuous by their absence from the list.

The Gaillon Hill Climb.

All motorists will remember the hill of "Gaillon," which for some few years past has been the scene of hill-climbing trials in the vicinity of Paris. The hill, although commonly named as above, rejoices really in the aristocratic title of "Sainte-Barbesous-Gaillon," and the competition was originally organised by the "Velo" in December, 1899. This year the event is to be reserved entirely to racing vehicles, which will make the climb on the 30th inst. So far, however, only three Gardner-Serpollet steam cars have been entered.

Motor-Boating in France.

With the object of furthering the motor-boat movement in France, a Chambre Syndicale de la Navigation Automobile has just been formed in Paris. Among the objects of the new body are the unification of the rules at present in force concerning automobile navigation, and of establishing for France a single gauge, and later an international gauge. M. A. Vedrine has been elected president, the vice-presidents being M. Varlet and M. Pitre, and the secretary and treasurer M. Pabanel.

Transmission Gear Efficiency Tests.

The comparative tests of transmission gear efficiency, which were to be held this month in the mechanical testing laboratory of the Conservatoire National des Arts et Metiers in Paris, have at the request of several manufacturers been postponed until January next. The object of these tests is to determine which types of transmission gear deliver the greatest percentage of power of the motor to the wheel rims, and the tests ought to give a good idea of the differences in efficiency between plain and ball bearings, and bevel gear and chain transmission, &c. In connection with the trials the French Automobile Club is offering medals for (1) the chain-driven car showing the highest efficiency, (2) ditto for bevel gear-driven cars, (3) the most efficient motor lorry with a variable speed gear, and (4) details of transmission earning special mention.

A Dirigible Balloon Competition.

A dirigible balloon competition is being organised in connection with the Liége International Exhibition, to be held next year. The tests will be held under the auspices of the Belgian Aero Club, between August 15th and October 15th, 1905. A prize of £4,000 is offered to the competitor who succeeds in making the journey from Liége to Spa and back twice. The distance between the two places is 26 kilometres.

A New German Car.

The Grafenstaden Engineering Works at Strasburg are taking up the construction of a new type of motor-car designed by Herr E. Bugatti, formerly with the German De Dietrich Company. The vehicles are to be known as the "Hermes-Simplex," and it is announced that a racing car is to be built for the eliminating trials for the German 1905 Gordon Bennett team.

A Big Contract.

It is announced from Brussels that the Pipe Company has secured a contract from an Italian syndicate for no less than 600 Pipe cars, part to have van bodies and the remainder to have two bodies each, so that they may be used either as lorries or public service vehicles.

Motor-boat Racing on the Seine.

A series of motor-boat races for the "Auto" Cup was held on the Seine at Maisons Lafitte on Sunday last. The cruiser section was won by M. Luce's Titan I., with Delahaye engine, its time for 50 kilometres being 2 h. 5 min. 55 sec. M. Tellier's La Rapee III., with 90-h.p. Panhard engine, secured the cup for racers by covering 100 kilometres in 2 h. 23 min 3 sec. The meeting was unfortunately attended by a disaster, the Mercedes I.A.F. being sunk with the mechanician on board. The accident is attributed to the narrowness of the river and the tremendous swirl set up by the action of the propellers of the competing vessels. Five boats had lined up for the start. On the pistol being fired they dashed off at a great pace, and before they could get clear of one another one vessel was bumped violently against the Mercedes, which was swamped and went down. The steersman managed to jump clear and swim ashore, but the mechanician was carried down with the boat and his body was not recovered until Monday.

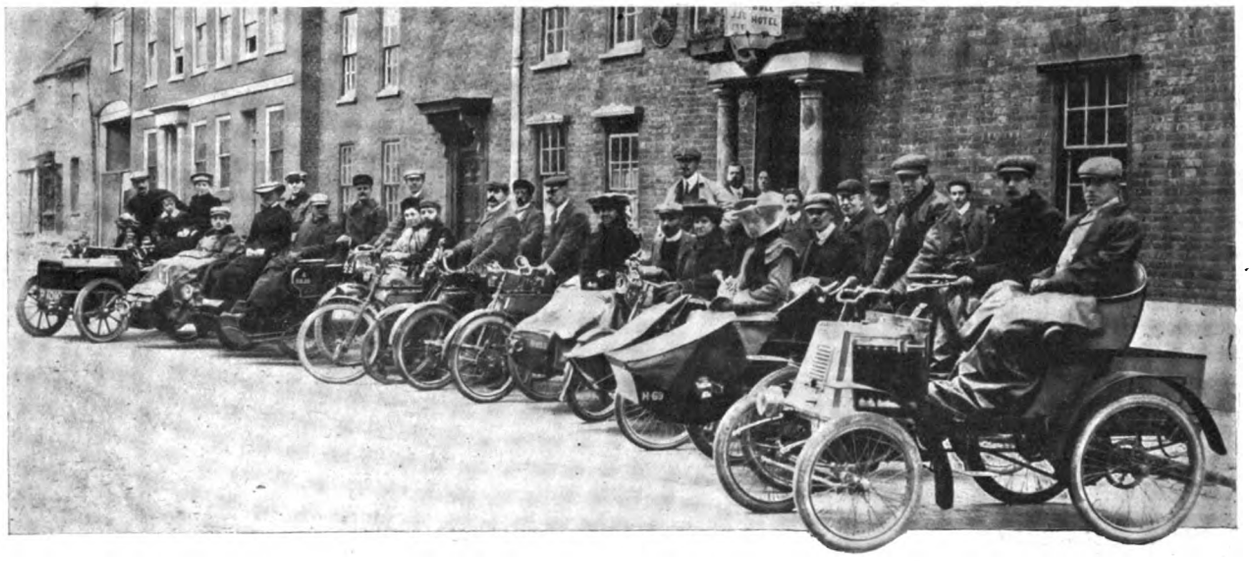

Photo by] The Motor-Cycle Club's closing Run for the 1904 Season. At the Bull Hotel, Redbourne, on Sunday last. *[E. W. Ashworth.*

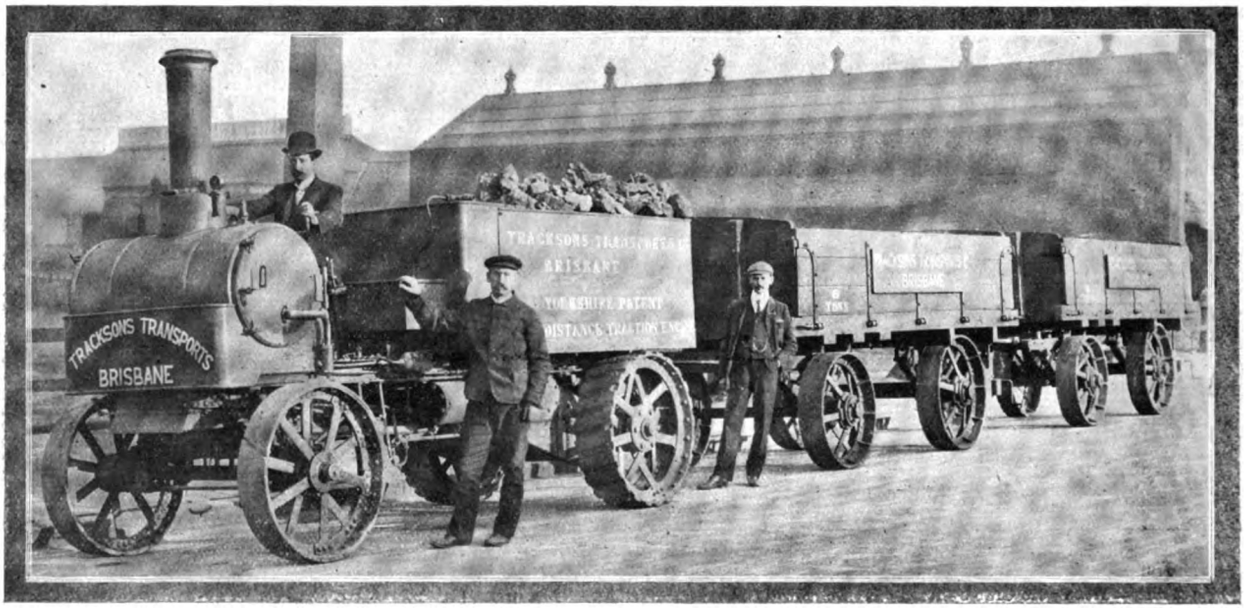

THE United Motor Industries, Limited, have taken large additional premises in Poland Street, London, W., which will be devoted entirely to storing and packing, while new workshops will enable them to execute all commands. In addition they will open next month a branch at the Sherbourne Works, Gosford Street, Coventry. All correspondence, however, should be addressed to 45, Great Marlborough Street, W., as hitherto.

Digitized by Google

COLD WEATHER PRECAUTIONS.

THERE is now a nip in the air which reminds us that the glories of summer are once again departing, and those motorists whose experience does not yet include winter use of their vehicles will probably welcome a few remarks on the special precautions necessary in their operation at this season of the year. Carelessness in leaving steam and petrol vehicles exposed to freezing temperatures with water in the tanks has been the cause of much annoyance in the past, and users are especially liable to suffer from this trouble at the beginning of the cold season, when a sudden drop in temperature often comes unexpectedly. In petrol vehicles the cracking of the engine cylinders is the most serious result of this oversight. With steam cars the piping and tanks are sure to burst if the water is allowed to freeze. In the case of petrol vehicles an efficient method of preventing the water from freezing at temperatures below the freezing point is to add glycerine in the proportion of about one part to every five of water. Calcium chloride is also a good specific against freezing, and by many is thought to be superior to glycerine. Probably the chloride of calcium will cause the water to withstand a somewhat lower temperature without freezing, but if it is impure it may cause corrosion in the water tanks or piping. It should therefore be obtained as chemically pure as possible. Various suggestions have been made to neutralize the presence of any acid in commercial chloride of calcium by the addition of some suitable alkali, such as potash, soda, or lime. Whether their effect would in time be detrimental in any way to the circulating system, we are not prepared to say definitely, but it is reasonable to state that they counteract the action of any acids present and probably without deleterious effects. A good solution density is obtained by using 5 pounds of hydrated calcium chloride crystals to 1 gallon of water. This solution will not freeze above zero Fahrenheit. A proportion of 8 pounds to the gallon is recommended by one authority, but in most cases the weaker solution is preferable, as there is less danger of too much water being allowed to evaporate and of trouble caused by crystals forming in the pipes and preventing circulation. Fresh water should be added frequently to keep the system filled and the solution at its normal density. Many owners prefer, of course, to go through the winter without using a non-freezing mixture, simply drawing off the circulation water, arguing that for the limited use they make of a car it is not worth while going to the bother and expense. In this case, however, pains must be taken to see that the draining of the pipes, tanks, etc., is done thoroughly, for a few drops of water left behind will do almost as much damage as a large quantity. A burst is a burst, and it will sometimes cost just as much to repair the ravages of one caused by imperfect draining of the water receptacles as one due to the neglect to take any precautions whatever. As long as a car is kept in commission through the winter it ought to be looked after properly; and there can be but one way of thinking about the matter of freezing, *i.e.*, that an ounce of prevention is worth a pound of cure.

Steam cars must not be exposed, when not in use, for any length of time to freezing temperatures. When left in the motor-house either all the water must be drawn from the tanks or else the house must be heated, the latter being probably the method most generally employed by steam-car owners. At periods of extreme cold lubricating oils have a greater viscosity than during the warm season, and to feed the oil at the same rate requires, therefore, a greater opening of the lubricator. When there is snow on the ground the traction or adhesion of the wheels is naturally reduced, and the liability to skid or side slip is increased. The same conditions prevail when frost sets in shortly after rain, and in all such cases special care in driving is necessary.

A Transport Train for Queensland. (*See page* 705.)

SIR JOHN DORINGTON, Bart., has become a motorist, his car having been delivered last week.

THE 40-h.p. Leon Bollée which won two silver medals in the touring classes at Blackpool has been sold to Lord Howard de Walden.

THE motor lamps exhibited by Mr. G. Ducellier at the International Show at St. Louis have received a diploma of "Hors Concours." Mr. Andre Godin personally put up M. Ducellier's exhibit at St. Louis while he was in the United States.

THE premises of Messrs. Sydney Lee and Co., Limited, in Furnival Street, Holborn, have been acquired by H.M. Government for the Patent Office, and the firm of auctioneers have opened new offices at 31, Brooke Street, Holborn, E.C. Messrs. Sydney Lee and Co. are about to erect large motor and engineering salerooms in the vicinity of Gray's Inn Road, W.C.

CAPTAIN THEO MASUI, who has introduced the Samson leather tread to the English market, has just issued a new price list and catalogue. A considerable reduction has taken place in the price of these treads, and a complete Samson outer cover, consisting of a Samson leather tread vulcanized on to a motor tyre casing, can be obtained at a price which is only moderately in excess of an ordinary outer cover.

SOME USEFUL NOTES.

We shall be glad to receive contributions for this column from motorists of experience. Suggestions and hints, briefly expressed, may prove valuable not only to novices, but also to many who have passed the early stages of practical automobilism.

◆ ◆ ◆

It is not often that a piston cracks, but it has happened, and if a case of want of compression should occur, and all the valves, etc., are perfect, remove the cylinder. Then scrape the deposit off the top of the piston, and a crack may be found, the mystery then being solved.

◆ ◆ ◆

The brakes of a motor-car may in various respects be compared to the safety valve of a steam boiler. Both are safety appliances, and must, to be reliable, be adjusted perfectly and kept in perfect repair. In stationary steam plants the safety valve is periodically lifted off its seat by the engineer or fireman to insure its not sticking to the seat by rusting, and thus giving a false sense of security. Similarly the brakes of automobiles, especially those running in hilly districts, should be examined periodically by their owners.

◆ ◆ ◆

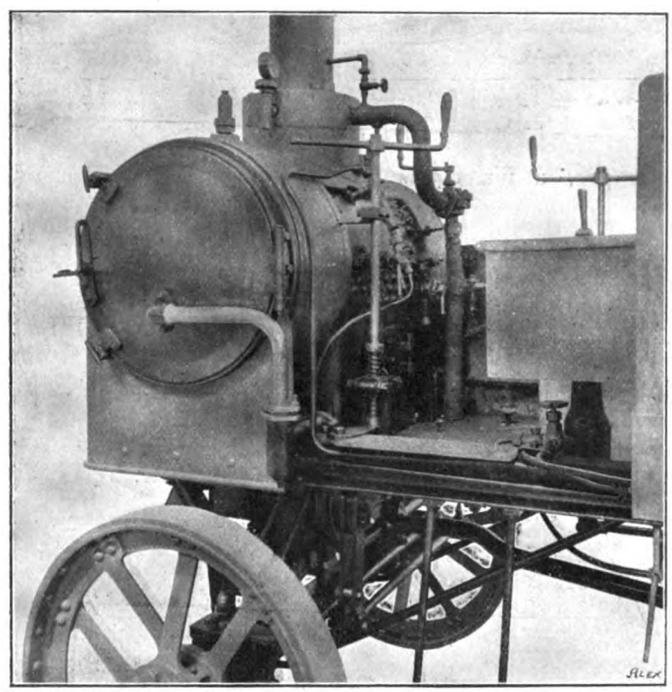
Most motorists have suffered at one time or another from burnt fingers after some necessary adjustment to a hot motor. A good way of minimising the chance of this is to cover the exhaust and water pipes, in such places where the hand or arm may touch them when groping after valve-springs, lifter, and the like, with a lagging of asbestos. This may be easily applied by wetting a strip of asbestos card, cut to suitable size, and coiling it round the pipe; when dry, it will adhere sufficiently. Of course, it is inadvisable to cover the pipe more than necessary.

◆ ◆ ◆

While on the subject of burns it may be useful to mention a valuable remedy, perhaps not universally familiar, namely, a strong aqueous solution of picric acid. This at once removes pain and to a great extent prevents blisters, at the expense merely of dyeing the affected part, for several days, of a colour that will probably match the wheels of the car.

◆ ◆ ◆

When sparking plugs are located in the cylinder in such a way that it is necessary, in order to remove them, to use a "box" or "socket" spanner, care must be taken that the spanner does not come in contact with the metal tip on the end of the porcelain, because if it presses against this tip or against the porcelain even lightly it is almost sure to crack the latter. For the same reason it is well to remove the thumb nut or screw which fastens the wire to the plug terminal. On some kinds of plugs the nut or screw is so large that it is almost impossible to put a box spanner on the plug without cramping the nut, and so cracking the porcelain. When connecting the wire to the plug, this screw or nut should be tightened up with the fingers, as, if pliers are used, the central wire which goes through the porcelain is likely to be twisted and loosened. On other types of plugs the binding screws are slotted so that a screwdriver can be used to tighten or loosen the screws. With these the screwdriver used should be a small one and handled with care.



◆ ◆ ◆

Often when a motorist has run up to, and come to a rest at, a point at which he desires to stop on top speed, a little difficulty will be found in returning the change speed lever to the neutral notch in the quadrant. This is due to the fact that the teeth of the toothed wheels on the sliding sleeve on the clutch shaft do not at the moment exactly coincide with the spaces between the toothed wheels on the gear-shaft, and the wheels will not pass each other. Of course, the clutch can be let in slightly, which would alter their position with regard to each other, but not infrequently the teeth still foul. The depression of the brake pedal, however, and the consequent grip of the brake bands on the drum, will, permitted by the slight play in the driving shaft, cause the gear-shaft to move just enough to permit the passage of the wheels on the sliding sleeve through their fellows, and allow the neutral notch to be at once attained.

STEAM TRANSPORT IN QUEENSLAND.

That the automobile is being regarded by the railway companies as a feeder rather than an enemy of their prosperity is becoming increasingly apparent in this country, and now the Australian railways are beginning to realise that it is to their advantage to encourage the use of mechanical traction on the ordinary roads to act as feeders.

For some considerable time Mr. James Trackson, of Brisbane, has been investigating the merits of various traction engines for the development of an idea for assisting the Queensland railways in reaching the agricultural settlements many miles from their lines. After a tour of inspection through the United States, the Continent, and Great Britain, he decided to place his orders in England for the engines required, and the Yorkshire Patent Steam Wagon Co., Ltd., were fortunate enough to secure the contract. We give an illustration on page 704 of the traction engine, which in this country would, of course, be allowed to proceed without the guiding and slowing presence of the man with the red flag—although whether such a wise bye-law prevails in Queensland is a matter of doubt. Some tests were recently

View of Footplate.

made with this traction engine and train on a windy and showery day, the roads selected being good but hilly. The traction engine weighed 5 tons 15 cwts., the load in the trailers was 10 tons, the weight of water and fuel on the traction engine 2 tons, making a total moving weight of 17 tons 15 cwts. In travelling fifteen miles, 228 lbs. of coke were consumed and 159½ gallons of water evaporated, the actual running time being two hours thirty-one minutes. The test was in every way satisfactory and Mr. Trackson is of opinion that the engines will be equally successful on the Australian roads. The maximum weight to be drawn is twelve tons at a rate of eight miles per hour. A trial mile was covered in 4¾ minutes.

The idea is that these traction engines will haul all kinds of produce, wool, horns, hides, etc., and that the Queensland Railway authorities will be able to quote through freights from the agricultural settlements to any railway station. There is no doubt a great future for such an enterprise, and the way in which the Queensland service is being initiated leads to the hope that large developments will early be made. Trackson Brothers, Limited, engineers, of Brisbane, are the sole representatives for these transports.

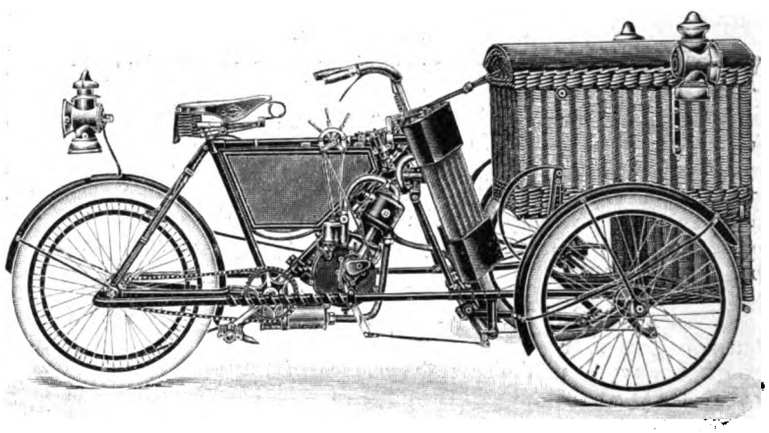
MOTOR CYCLING NEWS.

THE Croydon Motor Club held a Reliability Trial on Tuesday with a non-stop run to Brighton and back, starting from the headquarters. The first prize was a special gold medal, winner to also hold the "Brown" trophy—presented by the president, Mr. C. W. Brown—for twelve months. There were

The Start of the Croydon Motor Club's Reliability Trial on Tuesday.

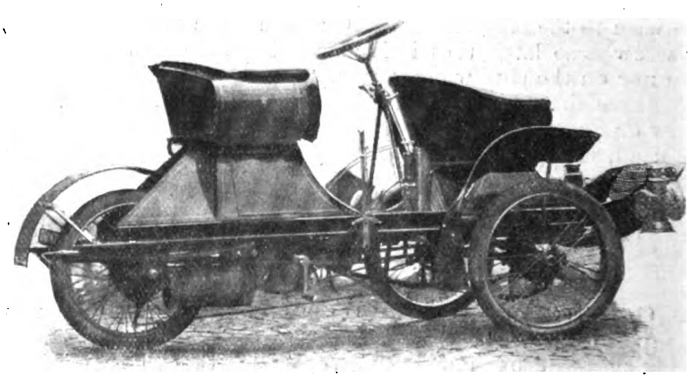
nine entries, but the general unfavourable condition of the roads reduced the actual number of starters to five, amongst those being Messrs. Bradbury Brothers, twin-cylinder Corydons; Mr. H. Martin, Excelsior; and Mr. E. J. Steel, Rover. Mr. C. W. Brown acted as starter and timekeeper, and the start was effected soon after eight a.m. from the Swan and Sugarloaf Hotel, a slight deviation from the actual route being taken to avoid the treacherous tram-lines to Purley. Mr. F. Bradbury dropped out at Crawley on the outward



A Military Motor Cyclist in the recent Dutch Manœuvres.

journey, while his brother gave up the contest soon after leaving Patcham on the return home. Messrs. Steel and Martin arrived back with the full complement of marks, and it was decided to run off this dead heat. The run off was a repetition of the first, except that Mr. Steel had to dismount in consequence of an obstruction from cattle, one mark being deducted for this traffic stop. Unless the matter should come up for further adjudication, Mr. Martin receives the first gold medal, and holds the cup for the second year in succession, while Mr. E. J. Steel takes the second prize. The hill-climbing competition was contested the following day (Wednesday) in the neighbourhood of Addington.

◆ ◆ ◆



THE first motor-bicycle race ever held in Roumania was run off a few days ago. The course was from Bucharest to Ploesti and back, a distance of 74 miles, which was covered by the winner, M. Bastiani, in 2 hrs. 33 min.

◆ ◆ ◆

THE Hubbards Motor and Engineering Company, Limited, of Coventry, has for some time been devoting attention to the production of a serviceable motor-cycle carrier, and has now put on the market the machine shown in the accompanying illustration. The motive power is supplied by a 3½-h.p. water-cooled engine, fitted with radiator and thermo-siphon water cooling. The transmission is by means of a ½-in. flat belt, a clutch being provided in connection with the driving pulley to give a free engine when desired. The wicker basket parcel-carrier has a waterproof top and is securely hung on springs; its dimensions are: length, 2 ft. 9 in.; width, 1 ft. 9 in.; and depth, 1 ft. 9 in. A small compartment is provided for the storage of tools, while the basket is so arranged that it can readily be removed and a passenger's seat substituted, converting the machine into an ordinary tri car.

◆ ◆ ◆

The 1905 Rexette, with suspension frame. This little car has a 5-h.p. motor and two-speed gear. Its steering gear, brake mechanism, and clutch are on the same lines as on an ordinary car.

◆ ◆ ◆

A MEETING of the Metropolitan District Association of the Cyclist Touring Club is to be held at the Society of Arts, John-street, Adelphi, London, W.C., on Wednesday next, when Mr. Basil Crump will give a lecture, with limelight views, on "The Possibilities of the Double-seated Motor-tricycle, with Notes on Continental Touring."

HERE AND THERE.

A MOTOR-TRAIN service is being established between Dublin and Howth.

MESSRS. FRISWELL, LIMITED, will hold an auction sale on Tuesday next, the 25th inst., at Southsea, on the premises of Messrs. G. H. Cox, Limited, 41, Castle Road.

MR. G. GOLDSCHMIDT, who is the agent for the "Zanardini" motor lamps, and sole concessionnaire for the "Jupiter" headlights, has taken up Merz's motor goggles with patent capsules. His new catalogue is nearly ready.

FOR the first time in many months, the exports of automobiles and parts from the United States, during August last, showed a decrease, the shipments attaining a value of £33,660, as contrasted with £34,226 in the corresponding month of 1903. For the eight months ending with August the figures are £264,499, as compared with £209,862 for the same period a year ago.

HEREWITH we illustrate one of the latest Argyll light delivery vans, built by the Hozier Engineering Company, Limited. The engine is a two-cylinder Aster, 88 mm. bore by 140 mm. stroke, fitted with mechanically operated inlet valves developing 13-b.h.p. A Longuemare carburettor is fitted; also a large honeycomb radiator with fan, the radiator being large enough to obviate the necessity of any other water tank. The gearing is the well-known Govan type, which has secured so many

awards. The body, which is designed to carry a load of 15 cwt. at a speed of fifteen miles per hour, is strongly made with thoroughly seasoned timbers. Its dimensions are:—Length, 5 ft. 5 in.; height, 4 ft. 9 in.; and width, 4 ft. 2 in. The wheels are of the artillery pattern, 30 in. diameter, Sirdar 3 in. solid rubber tyres being fitted to the back wheels, and Michelin pneumatic to the front wheels. The wheel base of the car is 8 ft. and the track 4 ft. The approximate weight of the complete vehicle is 16 cwt.

ONE of the most original experiments to discover or demonstrate the pulling power of an automobile was recently conducted by the experimental department of the Olds Motor Works in Detroit, U.S.A. A 10-h.p. Oldsmobile light tonneau was coupled to an electric tramcar, the trolley of which was held off the overhead conductor. The route was then followed until the tramcar was filled with passengers, fifty-one in all. Although the weight of the tramcar, with its passengers, was over 12 tons, the Oldsmobile succeeded in towing it at a good rate of speed.

THE long non-stop run on a small Clement-Talbot car, seating four persons, has been very successfully accomplished. The original distance of 600 miles was completed in 36 h. 10 min., an average of 16·59 miles per hour. 1,000 miles of actual running were accomplished in 54 h. 5 min., equal to 18·49 miles per hour. 1,000 miles full time occupied 61 h. 20 min., while 1,033 miles full time occupied 64 h. 5 min., an average of 15·949 miles per hour. After completing the 1,000 miles run, the vehicle, which remained throughout in excellent order, successfully climbed the Westerham Hill.

AT Swansea the two Oldsmobiles, now on the last 1,000 of their 3,000 miles tour, obtained a fresh stock of motor spirit, oils, etc, from Mr. Pryce Trow's garage.

UNDER the style of Osborn and Lord, a new firm of automobile engineers and agents has just been established at 33A, Broadway, Hammersmith. Both gentlemen are well known in the motoring world, Mr. F. J. Osborn having been connected with Messrs. Panhard and Levassor, whilst Mr. W. T. Lord was for two years manager for Messrs. C. S. Rolls and Co. New repair

The Non-Stop Run of the 9-h.p. Gladiator. The Car in Broad Street, Hereford. (*See page 687 last issue.*)

works have been erected at the side of the Empire Theatre at Shepherd's Bush, and these have been equipped with modern machinery, enabling all classes of motor repairs to be undertaken.

AT the Bucks Quarter Sessions on Tuesday, a labourer was charged with attempting to do bodily harm to Mr. William Partridge, who was driving his motor-car along the Bath road one Sunday night in June, when he saw a wire stretched across the road and attached to telegraph poles. Fortunately he had time to apply the brakes and to push the wire underneath his steering wheel. The case was dismissed.

THE photograph reproduced herewith depicts an "Orion" petrol motor-lorry lately supplied by Messrs Moss and Woodd to Messrs. Blundell, Spence and Company, Limited, colour and paint manufacturers, Hull. The lorry has been in regular work

for nearly three months, making six to seven short journeys daily in somewhat less than half the time that the horse-drawn vehicles take for the same journeys.

MR. ELLIS LEVER calls attention to the necessity for local authorities bestirring themselves in the direction of widening the existing narrow and congested highways of the country and constructing new means of communication. He advises those interested to go to Colwyn Bay to see what can be done by a progressive local authority at road-making, promenade-building, and tree-planting.

CORRESPONDENCE.

DOCTORS AND MOTOR-CARS.

To the Editor of *The Motor-Car Journal.*

Sir,—The motor-car has received, even in its comparatively early years, so much attention that little now remains to be said *pro* or *con.* But, like any live subject that is with us to stay, the great mass of arguments will bear repeating many times; and, therefore, the only excuse for this letter is to help to "hammer in" some accepted and important facts, with particular reference to the use of the motor-driven vehicle by physicians. It is admitted on all sides that the motor-car has come to stay, and is even now an important factor in the pleasure and the commercial worlds. The question often asked is what are the advantages of the motor-car? Well, anyone who has motored will say it is the greatest of pastimes. It is exhilarating, and whatever is exhilarating is conducive to a good body, mentally and physically. A jaunt of a few miles is quite as invigorating as a dip into the sea, and no special locality is necessary. One has only the pure air and bright sunshine. The dust is always left behind. Long distances may be covered, and the individual has the benefit of the ever-changing scenery and also of going somewhere. There is a fascination in a definite journey planned before-hand that is not experienced by simply driving out and back a few miles, as with a horse. Then, too, by this method of travel the natural enemy of man—close, stuffy railway carriages—is avoided. For the busy man and the invalid alike, nothing can compare with a pleasant, rapid run over a well-selected route of fifty or sixty miles, replete with natural scenery or historic interest.

The motor-car is safe. Hundreds of people are killed and maimed for life by the horse, "the friend of man." But we have been educated to the subject, just as we have to the fact that all mules will kick—and expect it. Reports of accidents to motor-cars are overdrawn, and a horse is mixed up in the affair in nine cases out of ten.

For the physician, with a riding practice, the motor-car is well-nigh indispensable in these days of hurry and competition. He can do more business, and do it better. Any physician who has no time to bother with one, is like the man who does not take any (or many) medical journals because he has no time to read them. The physician who has no motor-car has time to "bother" with it. It will save him weeks of time in a year. My car has earned its price many times over. The motor-car is not only a means by which the physician may make his calls in quicker time; it is also a means by which he may start upon them more promptly. Thus the new conveyance may be a very direct means of saving lives.—Yours truly,

A Satisfied Motoring M.D.

BELT TRANSMISSION.

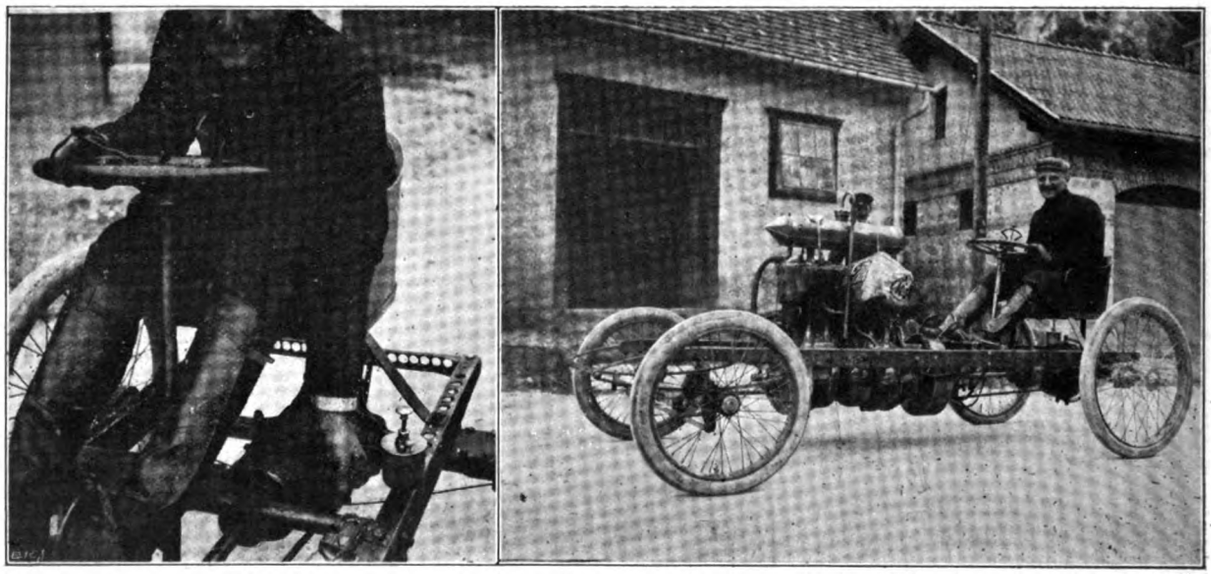
To the Editor of *The Motor-Car Journal.*

Sir,—Referring to "Assam's" letter in the *Journal* of the 8th inst., he has a poor opinion of the numerous enthusiasts of belt transmission. Surely they know something of modern gears. He, however, admits that a perfected belt car can be produced within reach of all; add to this the simplicity, capacity for hard wear, freedom from intricate mechanism and lubrication. I do not see why manufacturers should fight shy of such a vehicle for the man of moderate means, or the novice, who does not want to be bothered with gears, chains, &c., unless it is vested interests in plant and designs. If as much thought and expense had been applied to belt drives as to gears and their numerous associated weaknesses, we should by now have had a large industry on these lines.—Yours truly,

E. B.

To the Editor of *The Motor-Car Journal.*

Sir,—I have read Mr. C. Dent's remark in the last issue of the *Journal* with much interest, and, as one who has had eight years of belt transmission experience, most cordially agree with him. I have now a small F.N. two-cylinder car with a system of belt adjustment that allows me to place any tension on the belts while running by simply turning a key. This is a perfect success and has given no trouble with the belts for twelve months—the time I have had the car. I feel I must, in justice to the makers, also say a word in praise of the engines. I have never had to adjust a nut on them (except the contact breaker) or grind in a valve, and they run magnificently, and the car simply romps up any hill I have ever met, and this with full load—two or three. The car is extra strongly built, with finest finish, and has been much admired. It is silent on top speed, and, as the belts take off all strain on the engin s, their life would be prolonged indefinitely.—Yours truly,



H. Cove.

THE BLACKPOOL SPEED TRIALS.

To the Editor of *The Motor-Car Journal.*

Sir,—The word "automobile" explains itself. It matters not whether a vehicle is propelled by petrol, electricity, oil, or steam—it is an automobile all the same. Therefore, if the races are for automobiles, one kind of car is as eligible for entry as another. On making application to enter my steam car for the Blackpool trials on Monday last, the 10th inst., the entrance fee was taken and my car accepted in Classes C and S (cars value £250 and under), the car being a small 6½-h.p. Stanley. I went over to Blackpool on the 13th inst., as per their printed forms, to obtain the number and permit, and was refused on the grounds that steam would not be allowed to compete against petrol cars. They also asked me to take my entrance fee back. If the Automobile Club of Great Britain and Ireland is for the purpose of advancing automobilism generally, why should this form, namely, steam, be excluded? It would appear that the club is wrongly named, and should have been designated "Petrol Automobile Club." If that had been the case I could not have complained. I think the committee have acted very wrongly and foolishly in disqualifying this little car, and one is driven to the conclusion that they were afraid of it interfering with the success of the petrol cars they have an interest in and the manufactories from which they have been turned out. What is the result?—Yours truly,

B. 339.

The Spitz Light Racer driven by Hieronymous in the recent Hill-climbing Competition at Semmering, Austria. In the left illustration the driver is seen operating the change speed lever. [*Allgemeine Autom.obile Zeitung.*

To the Editor of *The Motor-Car Journal.*

Sir,—While watching the races at Blackpool last week I made the remark to my friend that it was strange no steam cars had entered. Imagine my surprise when he told me he knew of several who had wished to enter, but they had been "barred." "On what grounds?" I inquired. "Ah!" he said, "you evidently don't know much about the trade. You see our shining lights in the motor-car world are all interested in the petrol car, and apparently can arrange matters to suit themselves, hence they shut out the steam car, which goes to prove," said my friend, "that

Digitized by Google

they are afraid of it." For the life of me I cannot see why there should be this prejudice. With such cars as the White, Turner-Miesse, and Stanley in the market, and not to allow them to compete with petrol cars is beyond all reason. I take it as long as a vehicle is propelled mechanically it is a motor-car. Then what right have these "sportsmen" to bar the steam car? Perhaps some of your readers will be able to enlighten me.—Yours truly,

DISGUSTED.

THE USE OF THE ACCELERATOR.

TO THE EDITOR OF *The Motor-Car Journal*.

SIR,—Is it not generally allowed that the proper use of the accelerator is as a resource in reserve, to be brought into action to obtain higher speed on a level road, or in making a rush at a hill, or in changing to a higher speed? I am told by the representative of one of our best firms that the car should be driven "on the accelerator." Can this be right?

I am in much perplexity over a four-cylinder Aster engine fitted to a car I am driving. In making use of the accelerator for getting greater power from the engine, as stated above, so far from accelerating the engine, it slows down, sometimes to the point of stopping altogether, and so it is useless to depend on it in driving in traffic or when half-way up a hill. The engine generally picks up again, but only after a long delay, and when, perhaps, it is no longer required. The action of the accelerator ought to be immediate, and my difficulty is how to account for a long delay before it comes into action.—Yours truly,

A. T.

[The use of the accelerator is for giving extra power when wanted; by opening the same the engine should pick up immediately, unless overpowered on a hill or by too high gearing. With regard to "A. T.'s" trouble, we should think that the spring between the pedal or hand controller is too weak to overcome the governors. If this is strengthened the difficulty will probably be overcome.]

GEAR TROUBLES.

TO THE EDITOR OF *The Motor-Car Journal*.

SIR,—I have a "Baby Peugeot" car, but am unable to use it, on account of the difficulties in getting the gears in. The heavy preliminary grinding that took place before the gears could be got to engage in a short time completely wore out the first and second speed pinions, which I have had to recently renew. With these new gear wheels the trouble is as great as before, and after one day's work I found the teeth of pinions again so badly worn away that, unless the trouble can be got over, they will again require renewal. Although the gears slide in beautifully when the engine is at rest, at the very lowest speed of the engine excessive and continued jerking on the small gear lever is necessary to get the gear to engage, and usually several attempts have to be made before success, while in the meantime the teeth are being ground off. I shall be obliged for any advice as to how this difficulty can be got over, as at present my car is of no use to me. Possibly some of your readers may be able to help me in the matter. Can you give me the most satisfactory way of hardening gear pinion wheels?—Yours truly,

F. W. B.

SILENCERS.

TO THE EDITOR OF *The Motor-Car Journal*.

SIR,—I have a 12-h.p. Darracq, and, being desirous of getting it more silent, think of trying a fresh silencer.

I have had the Stanley and the Universal strongly recommended, but perhaps some of your readers could give their practical experience of these or other makes.—Yours truly,

223.

MOTOR AND HORSE-DRAWN TRAFFIC IN LONDON.

TO THE EDITOR OF *The Motor-Car Journal*.

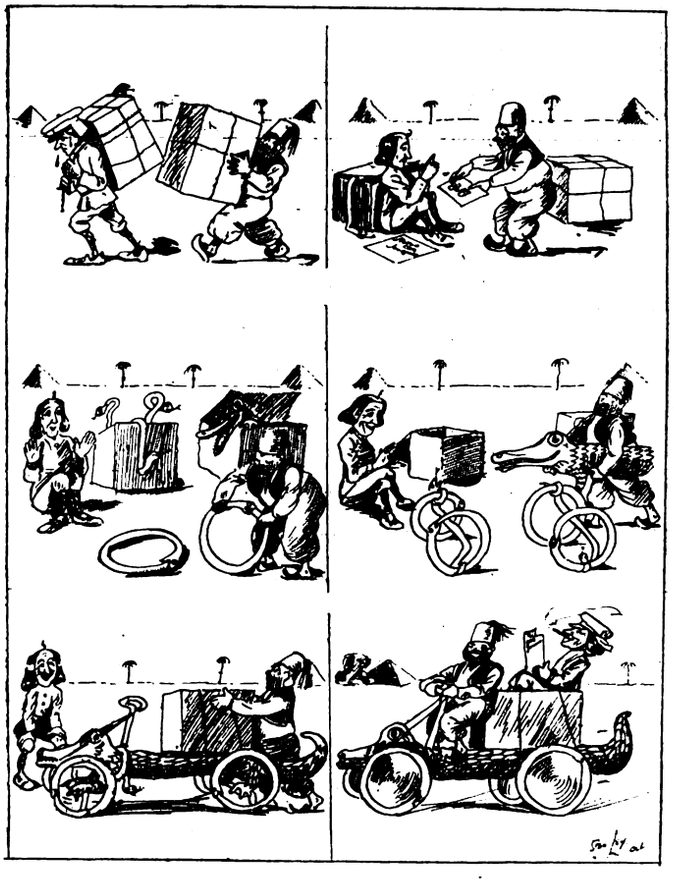
SIR,—We have some official facts to set against the prejudiced fancies which exist in the minds of some people in regard to the danger of motor traffic. In the returns of the Chief Commissioner of Police for London, the number of persons injured during the year by traffic of all sorts was 10,202. Of these 360 were injured by motors and light locomotives. The proportion, therefore, of accidents caused by horse traffic and motor traffic was approximately 95½ and 3½. On the other hand, about 95 per cent. of London traffic is still horse-drawn, which, as compared with the danger of the motor-car, judged by the number of accidents corrected by the proportionate amount of traffic, is as 5 to 4—a very clear proof of the comparative safety of the motor.—Yours truly,

H. GEORGE MORGAN.

BOWDEN WIRES.

TO THE EDITOR OF *The Motor-Car Journal*.

SIR,—As Mr. James R. Nisbet's reply to my letter of October 1st is rather misleading, I beg you will allow me to correct same. Mr. Nisbet argues that "I amply confirm his contention that the Bowden Syndicate suffers from the lack of understanding of the principles of the mechanism on the part of manufacturers." This is not correct, as, on the contrary, I pointed out that this slur on the intelligence of the trade neither justified him nor the system he controls in the slightest. The machine referred to was a Riley, whose productions are second to none in design and exquisite workmanship. Does Mr. Nisbet suggest that this well-known firm does not understand the Bowden mechanism? If so, he had better tell them. But I am sure he does not. It seems to me the system is more at fault than the manufacturers, because if the system or mechanism requires such expert fitting, it is quite clear the amateur has no chance at all to effect his own repairs on the road. My complaint is that they failed to render me the assistance I was willing to pay for. Fortunately, however, at the last moment I came across the Gripwell back-pedalling brake, made by Messrs. Wass and Cocks, the simplicity and effectiveness of which appealed to me at once; and, although I have no interest whatever in this firm, I can say that I never knew what it was to feel safe on my machine until I had this brake fitted. In fairness to Messrs. Bowden, Mr. Nisbet has written me saying that the matter has been investigated and that I was invited to drive the machine to his works for adjustments; but, as I explained at the time, the engine was being overhauled, and this could not be done.—Yours truly,



OWEN JOSEPH.

THE LIFE OF A MOTOR-CAR.

TO THE EDITOR OF *The Motor-Car Journal*.

SIR,—One of the questions most often put to his motoring friends by the new convert who is about to purchase a car, especially if he contemplates using it for professional or business purposes, is rather apt to puzzle them, as it is difficult to give a direct answer to "How long will it last?" As, however, there is no reason why a piece of mechanism should not "last" for ever, with due replacements of worn parts, though such a reply would hardly satisfy the inquirer, the question should more properly take the form: "What is to be allowed for depreciation and repair?" The usual figure of 15 per cent. may be taken as a fair estimate for the light car in careful hands, if about £1 per 1,000 miles be added as the cost of pneumatics; but the cheaper forms of vehicle will probably considerably exceed this, as will also really fast cars, the cost of upkeep rising rapidly with speeds over, say, a fifteen to eighteen miles average. The hard and constant use, too, that a doctor's practice involves may necessitate a rather higher figure; but, on the other hand, the more a car is worked the more marked is its economy, and in this latter case the saving over other means of transport would, where two horses are replaced, cover three times the amount mentioned. Where a vehicle is only used for pleasure purposes, however, a rational estimate of the above kind is almost impossible, and it can only be remarked that a car does not deteriorate with age, but only with use, while the fall in value due to "out-of-dateness" varies from accidental causes, and may generally be taken as less in the case of the productions of old-established firms than with newer ones.—Yours truly,

G. F. SWIFT.

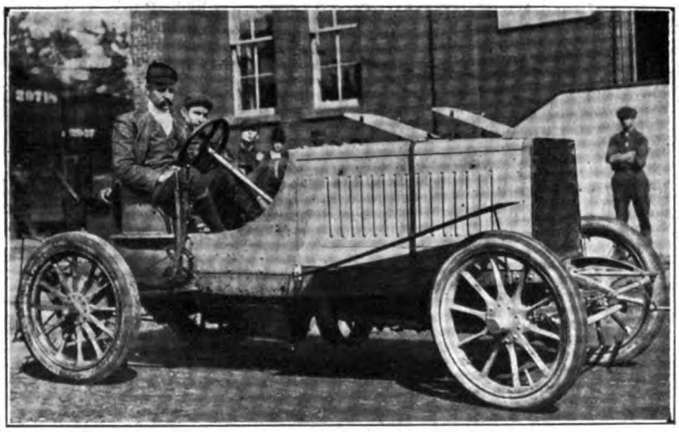
NON-SKID TREADS FOR TYRES.

To the Editor of *The Motor-Car Journal.*

Sir,—I am a regular reader of the *Journal*, from which I have had many valuable hints, and some time ago I read a favourable account of the Wilkinson non-skid treads, which induced me to try them; I regret to say that the result has been far from satisfactory. Within the first 200 miles one of the treads came right off, catching the mud-guard and smashing it completely, and the other only lasted about 600 or 700 miles before it split all round and is useless. Not only have the treads been a failure, but the method of fixing seems to have rotted the tyres and made them so that they cannot be used any more. Could you or any of your readers recommend a good non-skid band? My car is only an eight-horse, and I do not particularly want speed.—Yours truly,

J. H.



HOW TO SELECT A MOTOR-CAR.

To the Editor of *The Motor-Car Journal.*

Sir,—I don't think your correspondent "A Would-be Motorist" need be in any doubt as to what car to buy to meet his requirements. A study of the small car trials at Hereford clearly shows that one or two makers stand in the very front rank, and I should strongly recommend a careful examination of the Wolseley and De Dion—the latter I should think would be his selection, owing to the excellence of workmanship and design, and also its powerful brakes. It is an economical car to run, and the price well below the limit given by "A Would-be Motorist." I have no interest in De Dion cars, but know by my own experience and that of several friends how thoroughly good and reliable they are, and should your correspondent purchase one, I feel sure he will never regret it.

Let me strongly advise "A Would-be Motorist" to resist every persuasion to start his career as a motorist by buying a second-hand car; there may be some good ones, but the risk is not worth the apparent saving.—Yours truly,

N. 30.

Mr. Heath on the Panhard Car on which he won the Vanderbilt Cup Race.

ENGINE REPAIRS.

To the Editor of *The Motor-Car Journal.*

Sir,—In answer to "X. Y. Z.'s" letter in the last issue of the *Journal*, re motor repairs, I should feel inclined to think that either of the courses he suggests would be very expensive. But, of the three, he would perhaps find the first the cheapest, although perhaps not the best. The charge for a good man would undoubtedly be from 1s. to 2s. per hour. From personal experience, I would advise sending the car to a reliable firm and get repairs done, as no doubt in the end it would be better and cheaper. With regard to metalling the bearings, this requires to be done carefully, and should only be entrusted to a man who has had experience in this class of work; otherwise the metal would be likely to become loose and cause trouble.—Yours truly,

Ixion.

STEAM CARS.

To the Editor of *The Motor-Car Journal.*

Sir,—I may say that a few weeks ago I became the proud possessor of a "Conrad" steam car, and was quite in love with it. It arrived on a Tuesday night, and afforded exquisite pleasure in driving on Wednesday, Thursday and Friday morning. Prepared for a drive on Friday afternoon, with 100 lbs. steam, I remembered that the needle-valve next the tank was not turned on sufficiently in the morning, hence steam did not keep up so well. I therefore gave a few more turns, expecting there would be a "stop" when full on. But there was not, and the valve was blown into my hand. I at once pushed it back, but before I could give the necessary turn to engage the screw, the petrol fired and wrapped me in flame, burned my face and right hand—the latter badly, although the cuff of my coat was not even scorched—and in a few moments my car and the wood and iron stable in which it stood were smoking ruins. I have been among steam engines all my life, but did not sufficiently understand needle valves, especially those of American make.—Yours truly,

G. K.

To the Editor of *The Motor-Car Journal.*

Sir,—With reference to the subject of steam cars, I have found that a good plan is to now and then fill up the boiler with cold water, and then pump up with the hand-pump till the valve blows off. Any leak can thus be readily seen and put right. Then by opening the various taps the rush of water will clear any sediment out of the pipes. It is best to have a shut-off cock put in between the gauge glass and the boiler above the water level, so that by closing the same all steam or water must come from the bottom of the boiler, otherwise you may get a rush of steam only if the bottom ways are not clean. In my Locomobile I have fitted this device, and also arranged that by taking out a plug I can run a clearing wire along the various pipes. I have also replaced the old throttle with a screw-down valve; by this means I can regulate the steam to perfection. I find that my steam car does not cost so much for repairs as the petrol one I had, and the absence of sparking plugs, levers, clutches, gear box, etc., makes it a pleasure to drive; the only disadvantage is the filling up with water and spirit. I think that much could be done to make the mechanism more easily get-at-able, and I also think that if all the pipes were a size larger it would add to the success of the cars. I have used my machine in the heavy City traffic, and always found it well under control. The Editor has my address, and I should have much pleasure in showing my car to anyone, especially "Wiser Man." I think the steam car has been sadly neglected, and the prejudice against the same is for want of properly understanding it. I do not say that it is the best for every purpose. To-day I wanted to take out my car, and found one of the tyre valves leaked. It set me thinking of bygone days, when I rode a bicycle fitted with Fleuss tubeless tyres, on the flaps of which soft soap was rubbed. I took the valves out and gave them a dose of this useful domestic article, and it effectually stopped the escape of air. This hint might be useful to some other motorist.—Yours truly,

W. T. Warne.

The Blackpool Speed Trials.—We have received a long letter from the Duryea Company with regard to the Blackpool Motor Races, from which we take the following:—"We have to complain in the strongest possible manner of the treatment, which, largely, we believe, through the presence of trade rivals upon the committee, was meted out to us. In the first place, in the two-seated car classes an entirely new rule was introduced into motor-car competitions, stipulating that all cars should have four wheels. This did not trouble us, and was a perfectly fair regulation to make, if the committee so thought fit, but at the same time the price limit of the class was advanced to £250. We therefore removed the single steering-wheel, and replaced it by a standard axle and pair of steering wheels, converting the phaetonette into a phaeton. We won the class on Friday, beating all competitors, making better time than the second car by 11 sec., which is equal to about 400 yards on the mile run. The owner of the beaten car in the final protested, and the committee disqualified us and awarded the cup to the Speedwell Co., whose 10-h.p. car finished second. The complaint against us was that we were too cheap, and that our car did not legitimately come into the £250 class. We gave our explanation, but the committee 'did not consider it satisfactory.' We therefore place the facts—facts which we are prepared to prove—before the automobile public, and, in justice to ourselves, would ask you to publish them. They are as follows:—1. The car, as a three-wheeler, has been catalogued and sold at £200 all this season, and has competed at two race meetings in the £200 classes. 2. The interchange of double for single steering wheels is a change which we have been accustomed to make when desired for the past two years at a charge of £25, and we have never charged more than this figure. 3. This brought the actual figure for the particular car run to £225, but, as adding two wheels converted it to a phaeton, we entered it at phaeton price for a car fitted as this was, viz., £245. 4. The Speedwell Company in their objection pointed to the fact that our standard phaeton is listed at £295, ignoring the fact that these vehicles are fitted complete with Halliday top, storm apron, and ornamental leather dash board in front, as well as with two systems of water circulation, natural and forced. 5. At the time of the races, and at the time of the issue of the programme, our price for phaetons with double circulation system, but without top, &c., was £245, and we contend, therefore, that our car legitimately came within the regulations. 6. We can prove that although the price above referred to is a winter price, issued on September 15th, we have never yet sold a four-wheeled phaeton with single circulation system, and without top, apron, and dash, like the car we ran, for more than £250."

Cotton Tyres.—A correspondent wants the address of Messrs. Hyatts, Limited, the makers of the cotton motor tyres which have lately received some publicity.

Where Repair Shops are Needed.—H. Young writes:—"I cannot agree with E. A. Edsworth regarding repairers in Ramsgate. I have found everything very satisfactory at the "Motories," 22, West Cliff Road. The proprietor, Mr. Bowrah, is very willing, and has evidently had a good experience in repairs. I have no interest in Mr. Bowrah, but recommend him, as I found him an excellent repairer."

CLUBS AND ASSOCIATIONS.

SCOTTISH AUTOMOBILE CLUB.

THE Eastern Section had a run to Middleton on Wednesday of last week. The meet was in Charlotte Square, Edinburgh, where sixteen cars put in an appearance. As the Duke of Connaught was holding inspections in the vicinity, Captain George Macmillan, the hon. sec., who has a commission in the Automobile Corps, being on duty, was prevented from accompanying his club. The distance to Middleton Hall, the residence of Mr. E. E. Moss, being about twelve miles, was soon accomplished, and as the weather was all that could be desired and the roads good, some members made record spins. On arriving within the demesne they were received on the steps of the mansion by Mr. Moss, who only returned from London that day in order to be present. It is needless to say that the company of about seventy were entertained in a hospitable manner, and, though the afternoon soon closed in, the time was spent in a very enjoyable manner, as the estate was looking its best, being clothed in its autumn garb.

THE LADIES' CLUB.

THE Ladies' Automobile Club has elected the Hon. Mrs. Bingham to membership.

On Saturday last many members of the club were entertained by Mr. and Mrs. Wilson Noble at their beautiful place—Tangley Park, Guildford. Mrs. Wilson Noble had had a special road laid out round the house to enable the cars to drive on to the South Lawn. Members all said that they had had pleasant runs to Guildford, for, although it was cold and windy, there was little or no dust, and the roads were in good condition. Tea was served indoors, after which Mrs. Wilson Noble showed her guests over her interesting house. Among those present were:—Lady Cecil Scott Montagu (the first vice-president of the club), Mrs. Ainslie, with her nephew, Mr. Lafone, on a new 24-h.p. Panhard, Mrs. Alfred Bird and Miss Bird on a Georges Richard, Mr. and Mrs. Buttemer and friends on a 10-h.p. Decauville, Baron and Baroness Campbell von Laurentz (Serpollet), Miss Hill with her aunt, Miss Pilcher, on a 12-h.p. Ariel, Mr. and Mrs. Copland, 16-h.p. Clement, Mrs. Pigott, Lieut. T. E. Russell, 8-h.p. De Dion, Miss Christabel Browne and friends, 6-h.p. De Dion, Miss Crowthers, 9-h.p. Darracq, Miss Edith Schiff, with whom were Mr. Schiff and Miss d'Esterre Hughes, 24-h.p. Panhard.

SCOTTISH AUTOMOBILE CLUB (WESTERN SECTION).

THE "Anniversary" run in commemoration of the coming into operation of the Light Locomotives on Highways Act, 1896, which is one of the events of the Scottish year, took place on Saturday last to Ayr. This fixture differs from the others on the programme of the Section in that the cars meet in Glasgow instead of at the rendezvous and proceed in line through and out of the city. Well over fifty vehicles met in Blythswood Square sharp to the appointed hour of 10.30, and, headed by Mr. Adam, of Larchgrove, the chairman of the Section, who drove his 10-h.p. Wolseley, they left in long procession for the Ayrshire county town. Large numbers of interested spectators were gathered at the meeting-place and at various points in the city and *en route*. The arrangements were excellent, and every facility was given to the passage of the cars by them, as well as by the tramwaymen and the drivers of other vehicles, so much so that the long line of cars passed almost without stop or break through the busiest parts of the city. The committee's instruction that rank was to be kept, and no passing take place until the country had been reached, was absolutely adhered to. Similar courtesy was extended to the club at Kilmarnock and Ayr; and in the case of Kilmarnock especial pains were taken by the posting of a large force of constables to guide the drivers by a circuitous route, in order that they might escape the inconvenience and annoyance of negotiating the main route through the town, which is up for the laying of electric tram lines. The Ayrshire county road surveyors also showed consideration by arranging, after they were advised the previous day of the run, that on some stretches of road where repairs were proceeding and metal was being laid special steps be taken to have the new metal all rolled and other matters put right in time for the passing of the cars.

A considerable number of cars from outlying districts joined the route by the way or proceeded direct to Ayr, and by the early afternoon about 100 vehicles were recorded as "arrived" at the Station Hotel, Ayr, where the party lunched. Special and most satisfactory arrangements had been made for coping with the large party.

This meet constituted the record turn-out of privately-owned motor-cars yet seen in Scotland, and is fairly indicative of the growth of the club and of automobilism in the west of Scotland. The day was an ideal one for motoring, and the run was much enjoyed and passed off without untoward incident. The following were among the makes of cars represented:—Albion, Arrol-Johnston, Argyll, Beaufort, Cadillac, Darracq, Decauville, De Dietrich, Humber, Leon Bollée, James and Browne, Napier, New Orleans, Peugeot, Renault, St. Vincent, Wolseley, and Vauxhall.

BLACKHEATH.

THE Blackheath Automobile Club's concluding run to Chislehurst on Saturday last proved most enjoyable, the weather being ideal and roads good. Members met at the hon. secretary's house in Westcombe Park, arriving on a dozen cars, two tandems and two motor-bicycles, some coming from Bexley, Croydon, Earl's Court and north of the Thames to join in the run. A start was made at 3.30 for the Bull's Head Hotel at Chislehurst, a wide *detour* being made by several members before arriving there, whilst others went there direct and enjoyed a ramble on the adjoining Pauls Gray Common. Thirty-nine members and friends sat down to high tea, after which an informal general meeting was held, when suggestions were made with respect to social evenings to be held during the winter, a dance, progressive whist evening, concert and dinner being proposed. At the conclusion of the business an impromptu concert was held and a return journey made about 8.30 o'clock. The success of this concluding run speaks well for the future of the Club, which promises to become largely augmented next year by the accession of local and other motorists to its ranks.

LINCOLNSHIRE.

AT a committee meeting held at the Red Lion Hotel, Revesby, in accordance with the scheme for the amalgamation of the South Lincolnshire Automobile Club with the County Club, Dr. F. Miller, of Wrangle, was appointed to fill the place on the committee vacated by Dr. Pim. A letter was read from the clerk to the Horncastle Urban District Council asking if this club would assist in the erection of a sign-post in the Bull Ring, Horncastle. The matter was adjourned for inquiries to be made as to what local authority pays for the erection of sign-posts on the main roads. The following new members were, subject to the rules of the club, elected, viz.:—Mr. C. Pratt, Lincoln; Mr. J. Buck, Northolme, Gainsborough; Dr. W. H. Brook, Lincoln.

The special committee appointed by the club to investigate the subject of the use of alcohol for motive power have arranged for a paper entitled "The need for Duty-free Alcohol for Motor and Industrial Purposes, and its Profitable Production from home Agricultural Produce," to be read by Mr. W. R. Ormandy, D.Sc. (of Warrington), on

Friday, October 28th, 1904, at 8 p.m., in the theatre of the Municipal Technical School, Monk's Road, Lincoln. The chair will be taken by Mr. F. Howard Livens (President of the Lincoln Chamber of Commerce), and the committee have arranged for an informal dinner to be served at the club headquarters (Saracen's Head, Lincoln) on the same evening for the convenience of those attending the meeting.

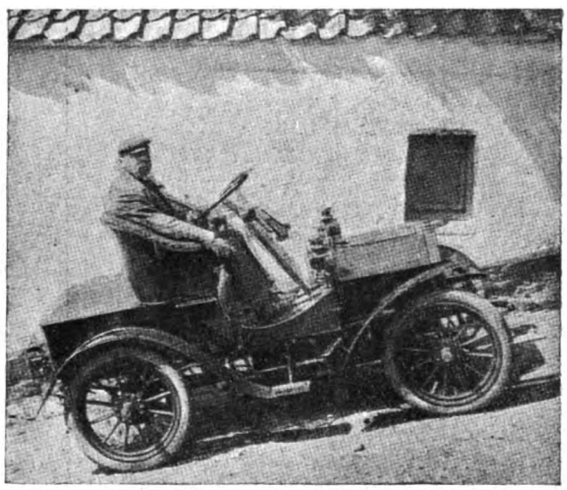
YORKSHIRE.

AT the Wentworth Woodhouse speed trials on the 1st, which were reported in our issue of the 8th, the official times of the first and second respectively in each class averaged as follows :—

CLASS 1 (single-cylinder up to 6-h.p.).

Owner.	Car.	Average miles per hour.
A. Masser	6-h.p. De Dion	24·95
Whitworth	6-h.p. Prunel	19·86

CLASS 2 (single-cylinder up to 6-h.p.).



W. R. Booth	8-h.p. De Dion	26·6
F. Bottomley	9-h.p. Renault	22·88
H. Martin	8-h.p. Renault	21

CLASS 3 (double-cylinder up to 12-h.p.).

Underwood	10-h.p. Argyll	31·3
Churchill	10-h.p. Hallamshire	26·15
Drew	7½-h.p. Wolseley	22·77

CLASS 4 (up to 16-h.p.)

Bayliss	14-h.p. Renault	38·05
Fawcett	15-h.p. Darracq	37·1

The accompanying illustration is reproduced from a photo sent us by the Siddeley Autocar Co. It depicts a 6-h.p. Siddeley car on a steep hill, which has to be ascended every time the owner leaves his residence. The gradient is 1 in 5, and illustrates the hill-climbing power of the little car in a striking manner.

CLASS 5 (up to 30-h.p.).

A. Farnell	28-h.p. Daimler	45
W. Jackson	20-h.p. Brush	40·8

CLASS 6 (30-h.p. and over).

H. R. Kirk	60-h.p. Mercedes	58·8

CLASS 7 (motor-bicycles, up to 2¾-h.p.).

G. Martin	2¾-h.p. Bat	30·5

CLASS 8 (motor-bicycles, over 3-h.p.).

C. Parker	3½-h.p. Griffon	38·75
O. Brooks	4½-h.p. De Dion	32·8

A DEVON APPEAL CASE.

IN regard to the impending appeal against the decision of the Wonford justices in fining a motorist 20s. and costs for refusing to bring his car to a standstill at Alphington when signalled to do so by Mr. Studd, jun., Mr. Alford applied to amend the conviction, on the ground that an appeal did not lie unless the penalty exceeded 20s.—The Chairman (Mr. W. T. Bayne) said they had no idea, in imposing a fine of 20s., that it precluded appeal. But it was impossible to amend the conviction. It was open to counsel to apply to Quarter Sessions to do so when the case was called.—The appellants are the Motor Union, and Mr. Alford, on behalf of that organisation, said the appeal could proceed if Mr. Studd would assent to the conviction being amended, but unfortunately he refused his assent, notwithstanding the expression of opinion of the magistrates at the hearing that they were desirous that an appeal should proceed.—The Chairman said it was now open to Mr. Alford to take what course he thought proper.

EXCESSIVE SPEED OR RECKLESS DRIVING.

LOUIS HADLEY, of Hunt End, was charged, under Section 1 of the Motor Car Act of 1903, with driving a motor-car recklessly in Redditch, on the 29th ult.—Mr. G. W. Hobson defended, and pleaded not guilty.—Police-constable Gittus stated about half-past ten at night he was on Church Green with Police-sergeant Bounton, and saw the defendant drive a motor-car round the corner and down Unicorn Hill at the rate of 18 to 20 miles an hour. So fast did the car travel that witness was unable to discern the number at all, but he followed defendant down to the railway station, and the sergeant took his name and address.—In answer to Mr. Hobson, the witness made no complaint as to the driving of the car, except that it was being driven at an excessive speed, and that there were people about.—Mr. Hobson submitted that they were not charged with driving at an excessive speed. They were charged with driving recklessly, and if they wished to prove negligence they should have taken the summons out under a different section. "Recklessly" meant driving in a careless manner and to the danger of the public.—In answer to Mr. Hobson, the witness again said that there was nothing in the actual driving of the car to complain about; it was the pace.—Mr. Hobson pointed out that as there were no local bye-laws laying down the speed of motors in the place in question to ten miles an hour, according to the Act they were allowed to travel at twenty miles an hour.—Colonel Bartleet expressed the opinion that it was reckless to drive a motor-car down Evesham Street at eighteen miles an hour.—Mr. Hobson: Not necessarily. One would have to pay regard to the circumstances of the case. To prove the case it must be shown that the driver was drunk, or had not hold of the handles, or did not sound his horn properly. Sitting with his back to the front of the car, for instance, would be very careless and reckless. Mr. Hobson asked the witness if, supposing the car had been going at six, eight, ten, or twelve miles an hour, he would consider an offence had been committed. After some discussion between Mr. Hobson and the Bench, the Chairman said the summons would be dismissed, as it was taken under the wrong section.

CASES AGAINST MOTORISTS.

Place.	Summoned for	Fine.
Reigate	Exceeding speed limit	£1, etc.
Isle of Wight	Having no licence for motor-cycle	£1, etc.
Dorchester	Leaving car without taking the precaution to prevent it being restarted in absence of motorist	5s. 6d. costs.
Exeter	Driving dangerously	40s., etc.
Darlington	Leaving car standing	Dismissed on payment of costs.
Dolgelly	Refusing to give name and address after an accident	£5, etc.
Perth	Failing to stop when requested	£2 10s.
Bradford	Failing to give sufficient warning of approach	Dismissed.
Belfast	Driving recklessly	20s. etc.
Birmingham	(1) No light; (2) Failing to produce licence	(1) £1; (2) £1
Dumbarton	Furious driving	Dismissed.
East Harling	Reckless driving	Dismissed.
York	Dangerous driving	Dismissed.
Bourne	Refusing to stop when requested	£2, etc.
Northampton	Driving recklessly	£5, etc.
Daresbury	Furious driving	£3, etc.
Beverley	Passing at rate of 15 miles an hour through part of the town where the new by-laws restrict the pace to 5 miles an hour	£1, etc.
Birmingham	Keeping motor-car without licence	£1 1s.
Kingston	Dangerous speed	£3.
Woolwich	(1) Allowing another person to use his motor-car licence; (2) aiding and abetting another person (his son) to drive the car without a licence.	(1) £5; (2) £2.
,,	Arising out of the foregoing case was another case charged with (1) driving the car without a licence; (2) giving a false name and address.	(1) £5; (2) £2.
York	Driving dangerously	Dismissed.
Bray	Driving dangerously	£5, etc.
Croydon	Driving at excessive speed	40s., etc.
Sheffield	Not stopping after accident	£2.
Warrington	Reckless driving	£10, etc.

THE

Motor-Car Journal.

VOL. VI.] LONDON, SATURDAY, OCTOBER 29, 1904. [No. 295.

Published Weekly by CORDINGLEY & CO., 39 & 40, Shoe Lane, London, E.C.

COMMENTS.

THANKS to the presence of a speed indicator on his car, Mr. Leonard Bayne has just secured a dismissal in a case at the West London Police Court, when he was summoned for travelling beyond the legal limit at Chiswick. The police evidence, founded on calculation with a stop-watch, was that the motor-car attained a speed of twenty-eight miles an hour. On the other hand, the defending motorist's indicator on the car only registered fifteen miles an hour, and Mr. Plowden, the magistrate, rightly acknowledging the difficulty in giving a fair decision in motor-car speed cases, went on to observe that he thought it just as likely that the indicator was as accurate as the stop-watch, and dismissed the summons. If other magistrates were equally fair minded and country justices as amenable to reason, the possession of an indicator would be a valuable economiser to all car owners. Certainly in this case, when the police swore to a speed of twenty-eight miles, and the indicator showed only fifteen miles, its presence was most useful.

◆ ◆ ◆

Petrol and Accidents.

THE keeping of petrol has been exempted from the Petroleum Acts by the Locomotives on Highways Act, 1896, which substitutes regulations made by the Secretary of State. When the owner of a motor-car can keep his spirit in accordance with these regulations he need not obtain a licence, but when he cannot comply with them he has the alternative of applying for a licence from the local authority. During the past year sixteen accidents in which petroleum spirit was involved were investigated by the inspectors of the London County Council. Eight fires on automobiles were reported during the twelve months. The accidents were not necessarily concerned with motor-cars, at least three having no remote association whatever with such vehicles. In one case a man attempted to light the gas in the coachhouse where a motor-cycle was kept. An explosion followed. Carelessness is generally the cause of such mishaps.

◆ ◆ ◆

In South Wales.

AUTOMOBILISM is making great headway in South Wales, and the South Wales and Monmouthshire Club has just removed to new rooms at the West Wharf, Cardiff, where they will have facilities for storing about forty cars. All members of automobile clubs in this country will have the free use of the garage provided their own organisations reciprocate the privilege. While the local automobile club is thus progressing, the Town Council of Newport (Mon.), has been endeavouring to secure the restriction of the speed of motor-cars in its streets to ten miles an hour. The case for the Corporation was that the main streets of the borough for about two miles form the only route for through and local traffic, and that already, owing to double lines of electric tramways and the traffic of the town, the roads are often congested; but it was pointed out in the course of the evidence that the trams already travelled at a speed greater than ten miles an hour. It seems rather unfair for any Corporation to seek to restrict the speed of other vehicles when they allow their own to travel at this rate.

◆ ◆ ◆

The Race in India.

CONSIDERABLE interest is being felt, not only in India, but in America and on the Continent, in the forthcoming Delhi to Bombay motor-car trials, the programme of which has already appeared in the *Journal*. From the British Chamber of Commerce in Paris we learn that some of the French motor cars are entering for the cup, to be competed for at Christmas time, and that they intend to make the best of the opportunity to sell cars and establish a good trade connection with India. The Secretary of the Chamber suggests that some of the British manufacturers should build a car that would stand knocking about on the rough earth roads in India. Mr. Arthur Hoare, one of the honorary secretaries, says that the road is in excellent condition, although two or three rivers will have to be negotiated. The Government, however, will probably bridge or ferry these, so that it will be possible for a really good race to take place. Lord Kitchener has given his patronage to the trials, and the military authorities of India are taking considerable interest in the event. It is gratifying, too, to learn that so many of the leading residents of our great Dependency are becoming ardent motorists, the latest accession to their ranks being the Hon. Mr. Justice Boddam, who has acquired a White steam landaulet.

◆ ◆ ◆

A "Passive Resister."

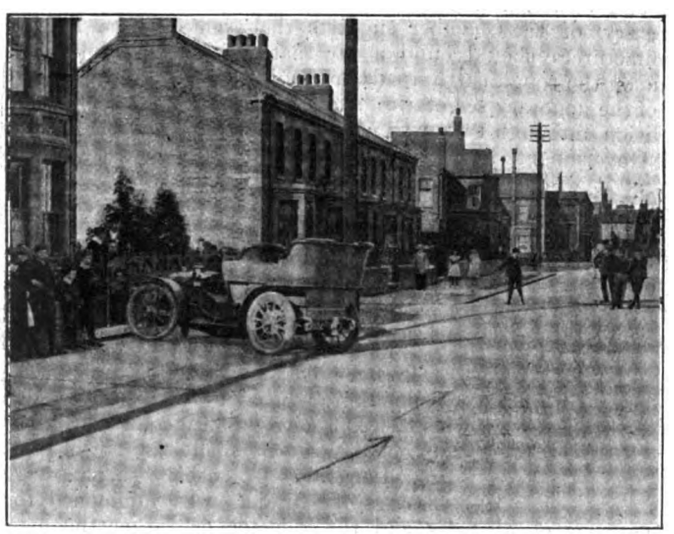
IN some quarters "passive resistance" is popular, and, having been adopted by some well-known public men, is now being accepted as a convenient way out of paying the rates by other people. A Basingstoke trader was summoned for non-payment of his rates, and the collector, or rather the man who should have collected, said the defendant objected to pay because the police set traps for motorists, and from what he paid deductions would be made to pay for these trappists. This new "passive resistance" is not likely to become general, nor will it be effective, but the idea indicates something of the dissatisfaction that exists in some quarters. The police rate, at one time, was intended as a contribution towards the expense of protecting property; now it bears the costs of trapping ourselves, while burglaries continue and housebreaking still has its votaries.

◆ ◆ ◆

Motor Cars in Canada.

ACCORDING to the Bulletin of the French Chamber of Commerce at Montreal, the automobile trade in Canada is steadily expanding. Several garages have been established at Montreal, in which city there are said to be nearly 200 automobiles, most of which are of American manufacture; a few, however, come from France. As the Canadian roads are not very good, solid and powerful cars are the ones most in demand. The American car sells well at present on account of its cheapness; but, in the opinion of our official contemporary, a well-constructed, fast-running car, with perfect steering apparatus, would find purchasers even at a high figure, as

Digitized by Google



amateurs of motoring are beginning to grasp the fact that, owing to the necessity for frequent repairs, the cheapest machines prove dear in the long run. It may be of interest to British manufacturers to note a suggestion of the Bulletin to the effect that several French firms should combine to establish a depot in Canada, to serve as a permanent exhibition of the advantages of French automobiles, with competent mechanics attached to execute repairs. At the present time difficulties are often raised at repairing shops when cars, other than American, are sent to be dealt with; complaints are made as to the lack of the necessary parts, the intricacy of the machinery, and so forth, which naturally tend to discourage the purchase of such cars.

◆ ◆ ◆

Universal Lights.

ALL the bodies which are interested in the rights of users of the roads should combine to secure legislation with regard to lights on vehicles. With the increase in the number of rapidly moving cars on the road, and the development of rural traffic generally, there is a greater necessity than ever before for the provision of lights on the slowest as well as the quickest vehicles. The matter is not merely one of equality, but of real danger if long neglected. Hitherto the agricultural classes have been credited with a powerful opposition to any alteration of the law in this respect, but now that accidents have become so frequent the necessity for universal lights is apparent, even to the most prejudiced persons.

◆ ◆ ◆

A Northampton Incident (*see page* 716).

◆ ◆ ◆

An Australian Reliability Trial.

THE Automobile Club of Victoria has granted its patronage to the projected reliability trial for motor-cars from Sydney to Melbourne, which will probably be held about the end of February next. A party of motorists are now motoring overland over the route with a view of inspecting the course, selecting the sections, etc., before drafting up the conditions which will govern the trial. The competition will be run on such lines that any contestant establishing faster time over any of the stages than that set out and allowed by the schedule will receive no more marks than the motorist who arrives to schedule time. In no case will a speed of more than twenty miles an hour be required to gain the maximum number of marks, the probable figures being seventeen or eighteen miles an hour for cars weighing over 1,000 lb., and fifteen or sixteen miles an hour for cars weighing under 1,000 lb. The competing vehicles will not be allowed to be touched after being placed in control at the end of each day's ride, all repairs and refilling having to be done during driving hours. The competition will be carried out in daylight, as the roads will not permit of night travelling.

A Fourfold Proposal with regard to Roads.

THE Automobile and Cycle Engineers Institute has inaugurated its winter session with an address from the president, Mr. H. Austin, who dwelt upon the importance of our common highways. These, he rightly pointed out, were as valuable a heritage to the British people as were their coalfields and iron mines. And yet there were hundreds of turnpike roads quite deserted. Tramways monopolise certain districts, but there are many miles of our highways yet to be utilised, and to secure this Mr. Austin suggests the establishment of some representative body with power to frame bye-laws for the safety of those who make use of such roads. Practical points to be immediately dealt with were (1) the uniform lighting of all vehicles, (2) rounding off corners where cross roads join, (3) high banks and hedges obstructing the view, (4) cleanliness of roads and streets. This quartette of proposals comprises a programme which might well be made the basis of legislation.

◆ ◆ ◆

Scottish Progress.

THE public opening of the new premises of the Caledonian Motor Car Company at Aberdeen was an event of considerable local ceremony. Dean f Guild Lyon declared the place opened and congratulated the chairman of the company (Mr. J. Brown) and the manager (Mr. Paterson) on the success that had already been attained. Twelve cars were drawn up in a row in Bon-Accord Street in front of the new premises, and then the procession proceeded by Union Street and Market Street to the Imperial Hotel, where the guests were entertained by the Company at luncheon. Mr. John Brown presided at the luncheon, and proposed "The King," which was loyally honoured. The toast of the afternoon, "Success to the Caledonian Motor Car Company, Limited," was given by Mr. W. L. Sleigh, who congratulated the shareholders of the Caledonian Company on acquiring such admirable premises for their trade. Mr. William Piper gave the health of the managing director of the company, and Mr. Paterson replied. Ex-Lord Provost Mearns proposed "The Guests," and Messrs. C. Friswell and Kingsbury responded. The Chairman, with whose name the toast was coupled, in responding, mentioned that the company had sold almost fifty motor-cars during the last financial year, and when they were told that some of these cars cost as much as over £1,000, they would see that it was a very big thing.

◆ ◆ ◆

Tarring the Highways.

MR. C. A. SMITH, the proprietor of the White Lion Hotel at Cobham, calls our attention to the tarring of the main road which runs through Cobham. In the middle of April last, Mr. T. E. Ware, the surveyor of the Epsom Rural District Council, treated half-a-mile with ordinary tar obtained from the local gas works. Under his directions the flint road was well swept and cleared of all dust, the tar being strewed on piping hot and then well brushed in. This dressing of the surface of the road has protected it from all wear, and even now there is not a loose stone to be seen. What dust there is on the surface has been blown on to it from the footpaths, etc. In addition to binding the road and saving the wear and tear, it has been found that there was no need to use a water-cart at all this season on this stretch of the great Portsmouth road. After rain the water rapidly drains away and the road is dry sooner than when not tarred. Great credit is due to Mr. Ware, who is said to have been the first surveyor to have experimented with tar on a main road in this country with the idea of doing away with the horrible dust nuisance. He first used tar as a road dressing on a footpath at Ewell, close to the railway station, nearly four years ago. It is estimated that the Cobham tarring cost £39, the area being about 7,500 yards, which works out at about 1½d. per square yard. This for a road twenty-one feet wide would come to about £64 per mile. The cost of watering roads for the summer season is generally estimated at £50 per mile; but, as it is now universally acknowledged that this system of laying the

Digitized by Google

dust is destructive to the road surfaces, it would seem that tarring roads is not so expensive as to prohibit its use more widely. Indeed, as local flints (costing 4s. 6d. per cartload) could then be used in repairing the highways instead of imported granite (costing 16s. 6d. per cartload), the money saved in the material and the water cart might well be spent in tarring.

◆ ◆ ◆

The Economy of Heavy Motor Vehicles.

HAVING made an excellent reputation as makers of roundabouts, Messrs. Savage Bros., Ltd., of King's Lynn, are now attaining distinction as makers of motor-lorries. At a luncheon given to some local friends last week Mr. F. W. Savage, the chairman of the company, said it was half a century since the business was established. During the whole of the time they had been more or less engaged in the making of road locomotives and wagons for road haulage. At the present time they were constructing vehicles to carry three, four, five, and six tons, and were also designing a vehicle of a smaller capacity to meet the requirements of their mineral

A Napier Racer on the Dustless Road at Cobham.

water friends, coal, ice and fruit merchants, etc. They were also manufacturing a light and small traction engine, which they had christened "The Little Samson," this engine meeting the wants of timber merchants and furniture removers who were wishful to attach mechanical traction to their present rolling stock. They were making a speciality of their steam sanitary wagon, and the one they had recently supplied to the Folkestone Corporation was giving most satisfactory results, and he was able to say, upon the authority of Mr. A. E. Nichols, Borough Engineer of Folkestone, that this one wagon used for street watering would do as much as six horses and six watering carts, the weekly cost of the steam wagon being £5 11s. as against £18 for the horses and watering carts.

◆ ◆ ◆

Public Services and Roads.

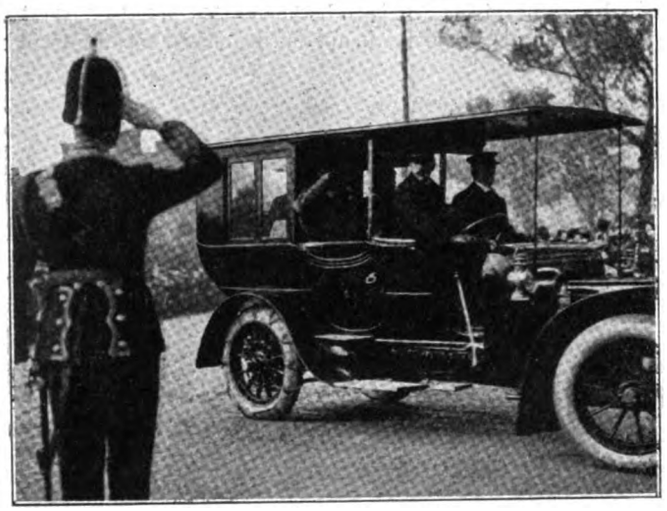
THE Canford Cliffs Motor Omnibus Company has been assuring the Bournemouth public that no variation in its routes will be made so long as the roads are good. This latter is a necessary condition for the success of any such service, and local authorities will do well not to ignore the implied suggestion in the notice of the Canford Cliffs Company. The failure of the District Council of Helston to do its duty in this respect has been held responsible for the withdrawal of the service which the Great Western Railway Company established in Cornwall. If private enterprise is to provide such public conveniences the local authorities must give their hearty co-operation.

◆ ◆ ◆

Official Repairers.

WE have received some inquiries of late with regard to the appointment of official repairers by the A.C.G.B.I. These are made on the recommendation of at least one member of the Club, and repairers who desire appointment have to fill in a form stating whether they understand the mechanism of cars, the works in which they served apprenticeship, any engineering certificates they hold, particulars of their staff of skilled men, garage accommodation, and other detailed information. Charges for garage and charging electric accumulators have also to be given. It is to be hoped the care that is taken by the Technical Committee in appointing official repairers will be sufficient to prevent any unqualified men appearing on their list, for there is no doubt that the motorist passing through a town and needing some slight repair has hitherto been largely at the mercy of folks whose qualifications he did not know at the start, but which he has found to be of an entirely negative character before they have finished with the job he has given them. Where motorists find really competent men, they can render a service to their confreres by submitting the names of such to the A.C.G.B.I.

◆ ◆ ◆



More from Rural Councils.

SEVERAL local Councils continue to pass resolutions and say nasty things with regard to motor vehicles and those who drive them. At Wivelsfield it has been resolved to make complaint to the County Council of the speed of cars, and to urge the authorities to take steps to minimise this danger to the public. At Ripon the deputy chairman of the Rural District Council has agreed with a proposal to have a conference with the West Riding Bench on the subject of the speed of motor-cars. He is, however, sensible enough to believe that time will work its

Digitized by Google

own reasonable way in this matter, and that ultimately little will be heard of what is now fairly a prominent subject for discussion. Perhaps one of the most remarkable resolutions adopted is that from Scotland, where, at a meeting held at Colmonell last week, and addressed by Mr. Cathcart Wason, whose Parliamentary antipathy to motor-cars has already received illustration, a resolution was adopted to the following effect:—"That, in view of the fact that in the Colmonell parish motors are constantly being driven at such a furious rate of speed that the lives of persons, especially children, are in great peril, and that ordinary farming operations are much hampered, this meeting regrets that the County Council of Ayrshire neglected to apply to the Secretary for Scotland for leave to restrict and limit the speed of motors, under sections 8 and 9 of the Act, within certain limits, through farm steadings, at cross roads and dangerous turns."

The King Returning from the Inspection of the Garrison at Woolwich

◆ ◆ ◆

From Dover to Putney.

MR. A. L. GUINNESS, whose recent acquisition of Mercedes IV. has already been chronicled in our columns, has had an eventful trip in this powerful boat. At Dover he had the greatest difficulty in discovering a pilot venturesome enough to accompany him on his voyage round the coast to the mouth of the Thames. A start was made at length from the ancient fort, and within six hours Mr. Guinness arrived at Putney, doubtless glad to reach his destination in safety. As a pioneer it has proved a demonstration of the capacity of the motor-boat for either sea or river.

◆ ◆ ◆

Drowsy Drivers.

ONLY those familiar with the roads of the county of Essex can appreciate the slovenly driving and the slumbering drivers which seem characteristic of the county. An instance of what we mean was mentioned at the Ongar Court the other day, when a careless driver was fined £3 and costs under the following circumstances. While the housekeeper and another servant of the Rev. Dr. Lewis, of Fyfield Rectory, were driving home at night they saw a lumbering hay-cart approaching them. They called out and pulled into the side of the road, but the cart came on and smashed the trap up, throwing the occupants to the ground. The driver of the hay-cart was overtaken by a policeman half an hour later, and was then found to be fast asleep, snugly wrapped up in sacks. He knew nothing of what had occurred, and said he never heard a sound. This is by no means an isolated case, and the authorities of Brentwood, Romford, Ilford, and East Ham might well undertake a campaign against the drowsy drivers who allow themselves to be led by their horses in quite a mechanical fashion from the market gardens to the London markets.

◆ ◆ ◆

Motor Tracks.

Now that track racing has proved so popular at Blackpool, additional interest attaches to the announcement that in connection with the scheme for the extension of the marine drive from Southport to Ainsdale-on-Sea, a distance of four miles, Mr. Weld-Blundell, lord of the manor, has decided that there shall be a separate motor track, marine drive, and promenade. The scheme is costly, but will greatly develop the district and find employment for a large number of men. Doubtless the presence of an automobile track where periodical meets can be held should prove an attractive feature at many a seaside resort, while its use on other occasions by private individuals should prove a magnetic influence in drawing visitors.

◆ ◆ ◆

First-class Railway Traffic.

FIRST-CLASS traffic is a perennial source of concern to railway managers, and its fluctuations are the subject of much earnest speech at the meetings of shareholders. At the Highland Railway Company's meeting the chairman has just been suggesting that the first-class traffic was a business with which they could not pretend to be thoroughly satisfied. There was no question that the development of the motor-car had seriously affected the first-class traffic of their company. It was very clear that a number of people who used to go to the Highlands by train and travelled first-class were now going by motor-car, and moving about the Highlands by automobile instead of taking the train from station to station as they used to do. The motor-car was undoubtedly a distinct hindrance to the development of the first-class traffic. The companies will have to tap other probable sources of revenue, including the extension of motor-car services, to bring passengers and goods from regions hitherto inaccessible to the railway.

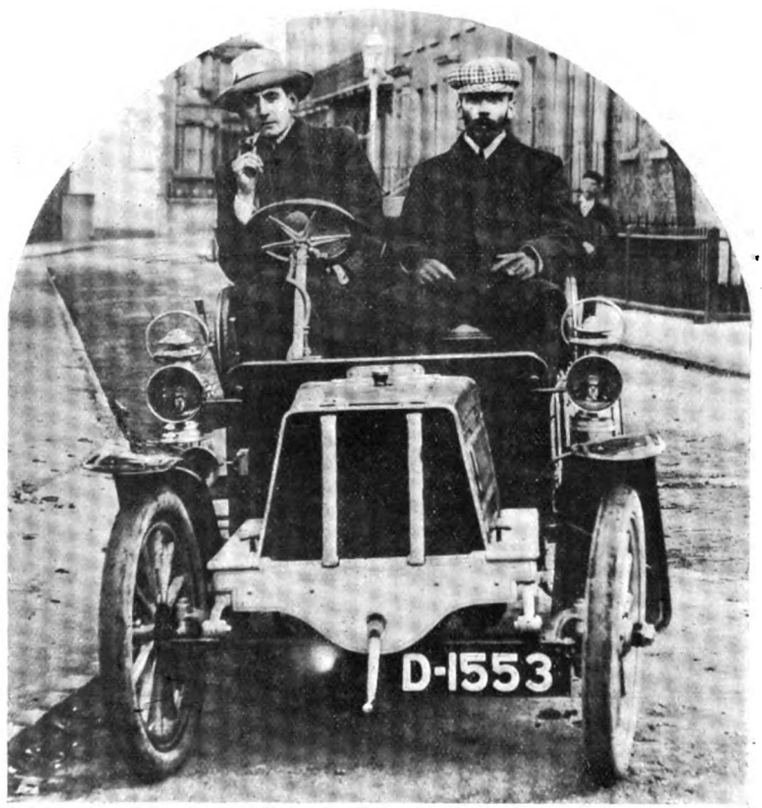
◆ ◆ ◆

The Need for Careful Drivers.

THAT there is need of care in the selection of drivers is constantly being impressed upon motorists. Inexperienced chauffeurs should be very careful not to take risks to their own vehicles; nor should they cause other drivers to do things that involve danger. The other day a valuable car was being driven through Northampton by its owner, who is an expert driver, when a light car, driven by a somewhat youthful chauffeur, darted out of a side street on the wrong side, and far too close to the corner. The driver of the larger automobile instantly recognised the danger and steered his vehicle on to the pavement, intending to run between the post and the house. The driver of the small car, instead of keeping to the left, turned to the right, and collided with the car that was endeavouring to avoid him. Our photograph on page 714 shows the result, the arrows indicating the direction in which the larger car was originally proceeding.

A FINE new motor-garage has just been completed near the stables at Buckingham Palace.

EARL TEMPLE, Mr. Lyell, M.P., and the Master of Elibank, M.P., have been on a political campaign in Scotland by motor-car.



THE marriage of Mr. H. W. Egerton, of Messrs. Mann and Egerton, of Norwich, to Miss Sorel-Cameron, of Hingham, occasioned quite a motor meet in the village.

DUNSTABLE is the title of the latest volume issued by the Homeland Association, Limited, to whose publications reference has been made already in these columns. It is written on the same general lines as the previous excellent volumes, and the illustrations are, if anything, above the average.

Digitized by Google

FROM WOLVERHAMPTON TO MARGATE ON A SMALL CAR.

FRIDAY morning broke fine, so, accompanied by a friend, writes a correspondent, I started off at about seven o'clock *en route* for Margate, *via* London. The car was a standard 7-h.p. two-cylinder Star, with seating accommodation for two, just out of the works. Everyone in the Midland district knows that the road from Wolverhampton to Birmingham is about the worst in existence—nothing but tramlines, with the exception of one stretch between Moxley and Wednesbury, and that stretch—well, pen cannot adequately describe it. I have often wondered whether an Improvement rate is in existence in that particular part. We trotted along, however, at a fair pace, and soon found ourselves through West Bromwich and nearing Birmingham. We reached the last named city at 7.45, and, after an almost endless struggling through roads torn up for trams, and various detours to gain the main road, we at length settled down to a nice steady run to Coventry. We soon passed Stonebridge and at about 8.30 we pulled up at the King's Head. We had one or two calls to make in the City of Spires, so that it was nearly 9.30 before we re-started. It is a most delightful run from Coventry to Daventry, a perfect road all the way, the stretch between the trees at Dunchurch being particularly delightful. The little car, despite the fact that it was new, was pulling grandly, fairly knocking off the miles, and in about three-quarters of an hour we were at the Wheatsheaf, Daventry. A little lubrication here, both for man and car, and at half-past ten we were on the road again. It was not far off Daventry that the only little trouble on the road to London occurred. We were going up one of the hills, about halfway between Daventry and Towcester, when one of the cylinders struck work. An examination revealed a broken sparking plug, which was speedily replaced.

The Car at the End of the Journey.

Our next stop was at Fenny Stratford. Having had nothing to eat since seven, a good meal was desirable. I can recommend the Swan Hotel as being a most hospitable house and most reasonable in its charges. We left this town at a little past one and did not stop before we reached Barnet. After a halt of a few minutes we ran straight on to London, arriving at the Great Central Garage at about three o'clock.

We left at five *en route* for Margate, *via* Maidstone. Crossing London and getting through the suburbs is always a tedious business, and it was some time before we reached Farningham. Here we experienced a little trouble—the second only through the journey. The engine appeared to be taking too much petrol, so a slight adjustment was made to the carburettor. This improved matters for a few miles, but the engine still appeared to be getting too much spirit, consequently we decided to examine things more closely at Maidstone. We did, and made the unpleasant discovery that the float was full of petrol. It is not really a serious trouble, but of course it is a nuisance when it happens, and I have covered I do not know how many miles motoring and never had a similar occurrence, and doubtless I shall cover many thousands of miles before it happens again. We then rectified the trouble, made a small hole and removed the petrol and sweated up the hole, and also the joint in the float where the original leak was.

The road from Maidstone to Canterbury is, to one who does not know it, very awkward. It is very narrow in places, and there are many dangerous hills and corners. Now, of course, we were travelling in the dark, and it was a particularly dark night, and, further, there were banks of mist rolling up now and again, so our progress was not very speedy. We backed the hill at Charing in fine style, using the top speed on part of the hill, and never dropping below the second. We stopped at Chilham, as the back lamp had ceased to shine, and found that the reason of this was lack of paraffin. The public-house had none, but the driver of quite the largest traction engine I have ever seen had some, and he obliged. The mist continued to block our progress until we were three miles the other side of Canterbury; after that, we ran straight ahead into Margate. It was well past eleven by the Clock Tower, and we were not sorry to sit down and eat and drink and be merry. I think, however, that the run will clearly demonstrate the value of a good small car. There was practically no trouble at all, and the average speed was certainly all that anyone could desire.

MESSRS. OFFORD, WILSON AND BARFIELD, of Birmingham, have recently introduced a set of apparatus specially designed for garages and similar places, for charging ignition cells with economy, no matter what the pressure of supply may be, or whether it be direct or alternating current. The set comprises a motor-generator with switches, resistances, meters, and a connection board; the apparatus is arranged for 200—230 volts supply, the dynamo giving 6 amperes at 35 volts, and it can be used for simultaneously charging six 60 ampere-hour motor-car cells, or eighteen 20 ampere-hour cycle cells, or a combination of these. The apparatus can be supplied fitted up to suit any requirements, and is connected up to an ordinary lamp-holder or wall socket. As the charging of small groups of cells from the mains through resistances is exceedingly wasteful, it is evident that a considerable economy can be effected by using this apparatus.

THE Alcohol Committee held its first meeting on Thursday last, and settled preliminaries.

MESSRS. WALSH, NICHOLLS AND CO., LIMITED, have removed to new works in the Dudley Road, Wolverhampton, where they have every facility for their growing trade in motor-car bonnets, radiators, tanks, lubricators, and silencers.

AN agricultural motor-wagon travelling at two miles an hour along a Hampshire road met a herd of cows, striking two with its wheels. The County Court Judge of Southampton held that until directed otherwise by the Court of Appeal he should lay down as law that when cattle or sheep were hurt by such an engine there was negligence on the part of the driver so long as the engine was kept in motion. The owners of the wagon appealed, but the Lord Chief Justice, sitting in a Divisional Court, agreed with the decision.

CONTINENTAL NOTES.

A Hill Climbing Competition at Marseilles.

La Provence Sportive of Marseilles, which introduced the idea of a hill-climbing competition with a standing start and a stopping finish, proposes to repeat the event on the 19th March next. The contest will be held on the Platrieres hill, on the road between Aix and Salon, and will be over a distance of 500 metres, the average gradient being 6·3 per cent. Only touring vehicles are eligible for entry, and instead of classification by horse-power, as hitherto, the cars will be classed according to the cost of the *chassis*.

Santos-Dumont's New Airship.

M. Santos-Dumont has begun the construction of a new airship (No. 13), by means of which he hopes to remain for a whole week in the air without descending. The form and construction of this balloon will differ considerably from those of its predecessors. The chief distinguishing feature will be that, instead of pumping air into the compensating balloon to allow for the loss of gas, the vapour of water, which is infinitely lighter, will be used. The airship is expected to be ready before the end of the year.

The Gaillon Hill Climb.

Château-Thierry over, all attention in French motoring circles is now centred on the hill climb at Gaillon, which takes place on Sunday next. The entries in the heavy-car class include two Serpollet steamers, a couple of Hotchkiss cars, and a six-cylinder Napier. In the motor-cycle section, two Griffons and three Magalis have been entered.

Racing in Italy.

A 10-kilometre race with a flying start, for the Targa d'Oro Cup, was held on the Borolenta - Padua road, in Italy, a few days ago. The best time was made by the Chevalier Florio, who, on an 80-h.p. Darracq, covered the distance in 4 min. 48 sec. Monastero, on a Marchand motor-bicycle, was second in 4 min. 53 sec.

Lanfranchi and his Peugeot Motor-Bicycle on which he established new kilometre and mile records at Dourdan. (*La France Automobile.*

Graduated Taxes on Motor-Cars.

The Government of the Grand Duchy of Hesse, Germany, is considering a schedule of taxes to be proposed on automobiles. It is proposed that the tax on motor-bicycles should be 5s. per year; on motor-tricycles, 10s.; 15s. for single-cylinder cars; 25s. for two-cylinder vehicles; 35s. for three-cylinder automobiles; and 50s. for cars with four-cylinder engines.

Automobile Trials in Belgium.

A technical committee has been formed in connection with the Automobile Club of Spa and Luxembourg to promote a series of automobile trials. It is proposed to organise a 500-kilometre reliability trial for touring cars and speed and consumption tests for motor-cycles.

The Gordon Bennett Race.

There will, after all, be no eliminating race to select the Italian team for the 1905 Gordon Bennett race, the Italian Automobile Club, notwithstanding the entries of two other concerns, having allotted the whole three places to the F.I.A.T. Company. The reason given for this decision is that the other concerns have not hitherto built racing cars, and that their works are not yet on a sufficient scale to undertake their construction.

Public Services in Germany.

Quite a number of new public services of motor-cars are projected in Germany. A syndicate has been formed to organise one between Kleke and Emmerich, while the establishment of a service between the town and railway station at Oberhof is under consideration. The health resort of Schonach, in the Black Forest, is also to be provided with a motor-'bus service connecting the town with the railway station at Triberg.

Motor-'Buses in Paris.

Following the example set by the London omnibus companies, the General Omnibus Company in Paris is making some experiments with a 24-h.p. Serpollet steam omnibus. The vehicle has been going over the difficult Bastille-Place Wagram route, selected on account of the thick traffic and big gradients, and by running under exactly the same conditions as the horse 'buses, with the usual stoppages, the steam vehicle is said to have covered the route in thirty minutes, as compared with the forty-five minutes usually taken.

Racing Cars for the 1905 Season.

It is announced that the Benz Co., of Mannheim, has decided to take part in all the leading racing events of the 1905 season, and have put in hand the construction of four special 80-h.p. racers, which will make their appearance at the Nice week.

1905 Models.

Details are beginning to leak out with regard to the 1905 models of the leading French builders. *La Vie Automobile* is authority for the statement that Messrs. De Dion-Bouton and Co. will adopt a *train-balladeur*, or sliding pinion type of gear box, on its 8-h.p., 10-h.p., 12-h.p., and 15-h.p. cars for next season, together with a new type of clutch. The separate clutch system of change-speed gear is to be retained on the 6-h.p. car, but it will be similar to that used on this year's 8-h.p. vehicle, giving three speeds forward and a reverse. As regards the Panhard 1905 models it is stated that these will show but little change from this year's cars. A new touring vehicle of 50-h.p. is, however, being introduced.

THE Harrow Town Council contemplates asking for Grove Hill, Harrow, to be closed to motorists, and, despite the receipt of a letter from the Middlesex County Council, in which the representations of the Automobile Club were urged, has adhered to its former decision. An inquiry into the matter will be held under the authority of the Local Government Board.

THE Thames Conservancy Board has referred to the Upper River Committee the question whether special regulations should be made for the licensing of petrol launches on the river. These launches have increased from 46 in 1903 to 273 this year.

Digitized by Google

The Maxim Petrol Motor Landaulet.

THE accompanying illustration shows the 24-h.p. "Maxim" landaulet, one of the latest productions of the London General Automobile Company, Limited. The frame is made of steel of tapered channel section with continuous

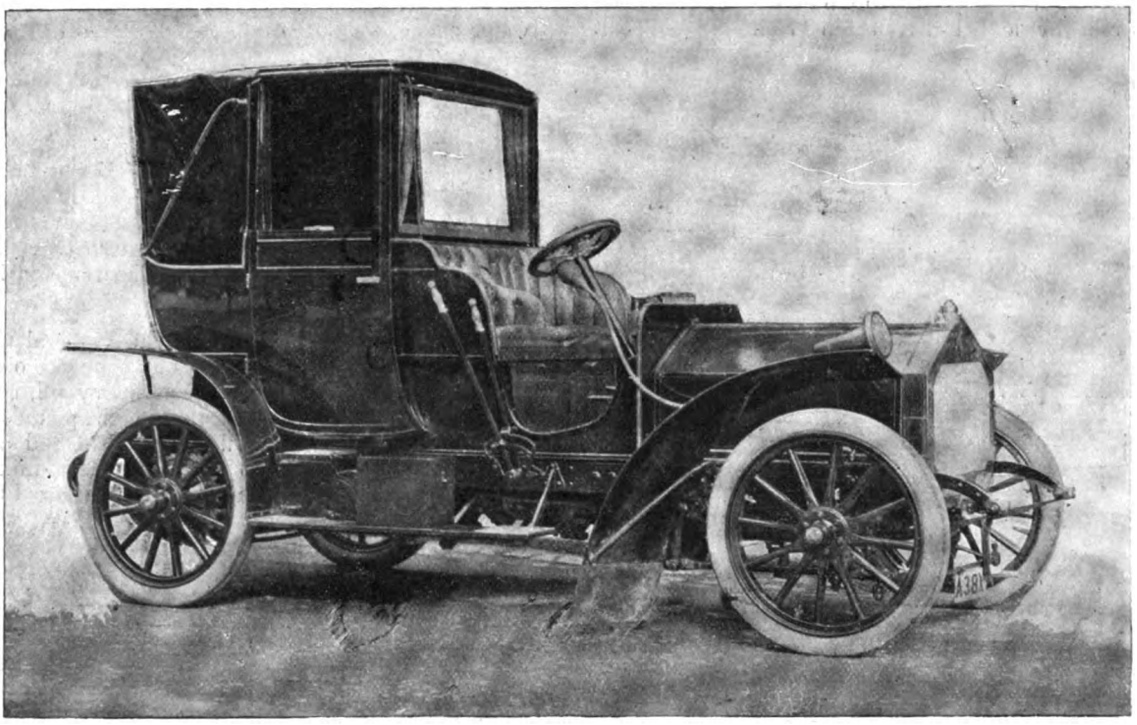

Fig 1.—General View of the Car.

hangers, the width in front of the dash-board being 33½ ins., and at the rear 35½in.

The springs are of the Grasshopper type, 50 in. long at the back, and 39 in. at the front. The hangers rest on inserted steel rollers, which prevent great wear of the spring bolts, and releases them of all weight.

The motor is vertical and has four cylinders 100 by 120 mm. stroke developing 24-h-h.p. when running at the normal speed of 1,000 revs. per minute. The cylinders are made of special close-grained iron, cast solid with their jackets, and are fitted with pistons having three piston rings. They are water-cooled, with ample cooling surface. The connecting rod is forged from tool steel and fitted with phosphor bronze gudgeon at the big end. The crank shaft, forged from solid nickel steel case hardened in all the journals, is carried on three main bearings fitted with ring lubrication. The crank chamber is of aluminium and is fitted with large and accessible inspection covers. All the valves, both inlet and exhaust, are operated from one cam shaft. They are of large diameter and interchangeable. The inlet valves are placed on the tops of the cylinders and by use of bridges each pair of valves are entirely removable. The exhaust valves are placed on the sides of the cylinders, and are accessible by means of box screws. The governor is of the vertical centrifugal type, and acts on the carburettor, which is of a special design. The ignition is high tension electric, by means of accumulator and induction coil with tremblers. The commutator, of the simple wipe pattern, is gear-driven, entirely enclosed, and dust and damp proof.

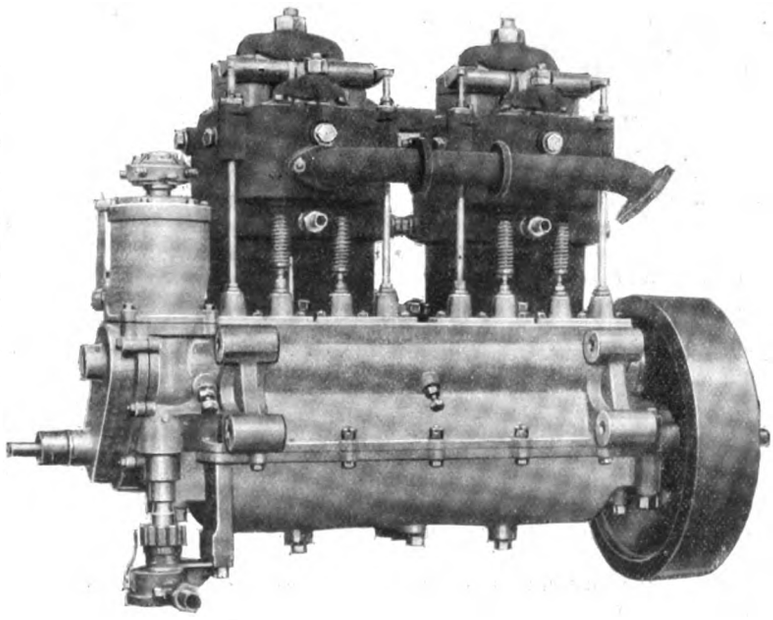

Fig. 2.—The Maxim 24-h.p. Motor.

The clutch is of the leather-faced cone type. The internal part of the clutch is freely mounted on the extension of the crank shaft, and is connected to a coupling between the engine and the gear box. The clutch spring is of the internal type, and is mounted on the crank-shaft, so that the thrust is entirely self-contained and rendered accessible by a special device.

The gear-box is adapted to give three speeds forward and a reverse controlled by one lever. On the top speed there is a direct drive through the gear-box, and when this is in operation the secondary shaft does not revolve. The gear-box is very accessible, as also is the differential, which is sepa-

Digitized by Google

rate from the bevel gear conveying the power from the change speed gear shaft to the countershaft. From the latter to the rear road wheels the transmission is by side chains.

There are two independent brakes, one operated by the right pedal, which acts on a brake drum fitted on the bevel drive, and internal expanding brakes in the hubs of the rear wheels controlled by a hand lever. By means of a compensating bar the latter act simultaneously. Both brakes when applied automatically draw the clutch; they are also both double-acting. The sprag is a ratchet acting on a toothed wheel fitted to the brake drum on the bevel drive.

The radiator is of the honeycomb pattern and is cooled by induced draft by a belt-driven fan running on ball

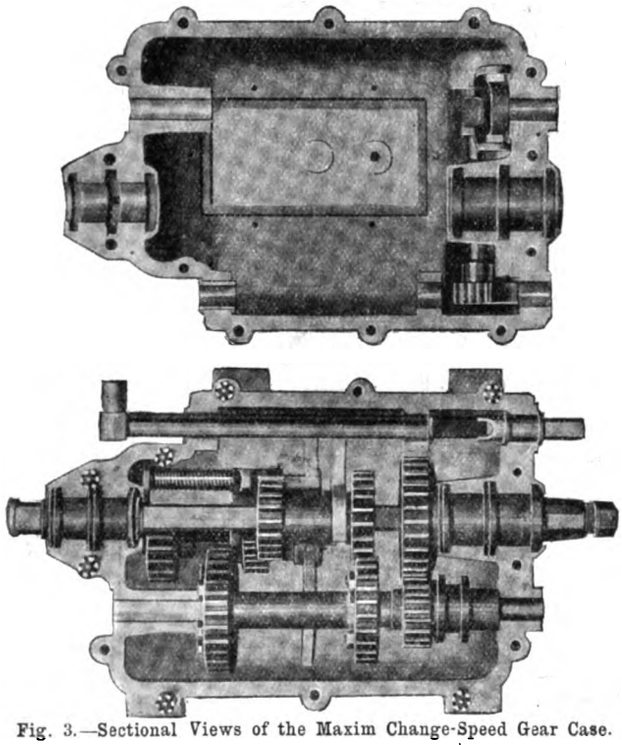

Fig. 3.—Sectional Views of the Maxim Change-Speed Gear Case.

bearings and placed immediately behind the radiator. The cooling water is circulated by means of a gear-driven pump. The bonnet is of the Mercedes type. The steering is of the irreversible type with worm and worm wheel enclosed in an oil-tight box. The friction due to the vertical load is reduced by ball bearings. The levers for the governor and ignition are fixed on top of the steering wheel. All parts are lubricated automatically by pressure, and tubes with separate sight feeds lead to all bearings. The petrol tank is placed at the back of the *chassis* and fitted with a combined pressure and gravity feed worked by a regulating valve on the exhaust. We may add that the body is hinged so as to render the whole of the mechanism accessible. The wheel base of the car is 9 ft. 2 in. and the track 4 ft. 7¾ in.

ST. ANNE'S HOTEL at Buxton has now a well-equipped garage.

THE Automobile Club of the Yonne has just been formed at Auxerre, France, with M. J. Guillet as first president.

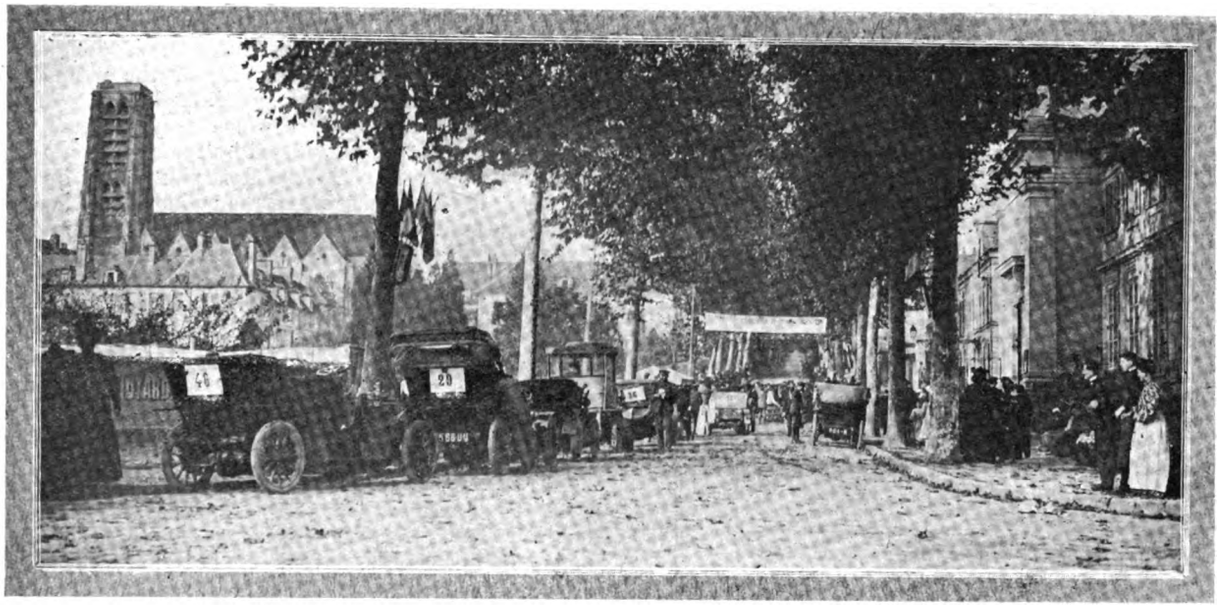
MR. T. K. HINDS has opened a motor-car depot at Kildare, an ancient town on the Gordon Bennett race course of 1903.

FROM Messrs. Anthony Treherne and Company, Limited, comes a new volume entitled "Three Men in a Motor Car," by Mr. H. R. Maxsted, in which we have the interesting chronicle of a couple of tours, aggregating over 5,000 kilometres, undertaken by a party of ardent motorists. They seem to have had a thoroughly enjoyable time, not only in the south of Europe, but in Algiers and other distant places, and have introduced some excellent travel notes in the account of their journey.

SOME USEFUL NOTES.

CARS which are constantly in operation during the winter are preferably kept in a heated stable. If kept in a cold place the bearings will be found exceedingly stiff when the machine is taken out in frosty weather, which makes them run much harder. Besides, with many forms of carburettor, difficulties are experienced in starting the motor.

IF acetylene lamps are to be expected to give satisfactory service, the gas generators should be thoroughly clean every time they are filled. A good way to do this is to use a hose and water under pressure, compressing the end of the hose so as to make the water stream out forcibly. See that all the residue is thoroughly removed from the generator before refilling with carbide.



ACETYLENE lamps are sometimes not hung properly on the brackets. The latter may be inclined forward from the vertical, causing the light to strike the road close to the car, and showing very little light ahead, or they may be inclined backward, causing the light to shine upwards, and leaving the road close to the car in comparative darkness. The remedy in both cases is obvious.

DRIVING chains should be cleaned several times during the season by thoroughly washing out the old oil and dirt with paraffin, and then soaking in warm heavy oil, so that it will run into the bearings; or in a mixture of eight pounds, approximately, of tallow, two pounds of flake graphite and a quart of heavy lubricating oil melted up together. The mixture should be heated until liquid and the chain then allowed to lie in it until the whole is a solid mass. The outside of the chain should afterwards be wiped clean. In replacing the chain adjust it so that it will show a little slack at the bottom when tight at the top.

WHEN motoring, if matches cannot be had, and a light is wanted, it may be obtained in the following way, if the car is fitted with accumulator and coil ignition:—Disconnect one of the high tension wires from its plug; place the free end of this wire in such a position that it lays about a quarter of an inch away from the cylinder casting. A small piece of cotton waste or a piece of paper should now be saturated with petrol and placed over the free end of the ignition wire. Switch on the current and slowly turn the starting handle of the motor. When the spark jumps from the free end of the disconnected wire to the cylinder casting, it will set the paper or waste on fire. Extreme care must be taken not to allow the blazing waste or paper to fall into the "apron," underneath the motor, if one is used. This "apron" is usually covered with grease and oil, and if it catches fire it may imperil the car.

Now that the bad season has set in, motorists have to resign themselves to stabling their car for a longer or shorter period, and should follow the advice given by Messrs. Michelin as to the care to be given to pneumatic tyres during the winter. As a rule, towards the end of the season motorists are less particular about the condition of the tyres on their cars, and less anxious as to sending them to be repaired directly they show any signs of wear. In fact, many delay sending them to the manufacturers until they cannot run any longer. Others take off the tyres, wrap them up carefully, and put them away according to all the rules for good preservation laid down by makers. And when the fine weather returns and they wish to "motor" again, they are surprised to find that the tyres cannot be used till they have undergone some repairs; and consequently they have either to wait till these repairs are executed, or buy new tyres. It is much more simple, in order to prevent this contingency, to send all faulty tyres to the repairers at once. The repairs will be done much quicker now than in the spring, when motor tyre repairers will be overwhelmed with orders, and besides, the tyres will be preserved just as well during the bad season after they have been repaired.

The Cars lined up at the Starting Point of the Chateau-Thierry Hill Climb.

THE CHATEAU-THIERRY HILL-CLIMBING COMPETITION.

THE annual hill-climbing competition organised by the "Auto" was held at Chateau-Thierry on Sunday last, the event this year being reserved entirely to touring vehicles. The contest was over a mile course on a hill known as the Chesneaux, and was made from a standing start. The hill begins right in the town, and is mounted by a narrow street very badly paved, there being, in addition, a bend at the last and most difficult part of the climb. The conditions are therefore very severe, as the hill, starting with a fairly easy grade, becomes steeper and steeper until the summit is reached. When the list was closed it was found that no less than seventy-four entries were received, and of these sixty-three were weighed in on Saturday last.

In the class for motor-bicycles having a cylinder capacity of a third of a litre there were a dozen competitors, the best time being made by M. Collomb on a Magali bicycle with Buchet motor, 1 min. 43 4-5 sec. (equal to over 35 miles per hour). Bac, also on a Magali with Deckert motor, was second in 1 min. 47 2-5 sec. The Magali is a new machine which has quickly come into repute; a description of it is given elsewhere in the present issue. The third place was taken by M. Le Metais on a German machine known as the Neckarsulm, in 1 min. 54 4-5 sec.

In the class for two-seated cars costing less than £160 the victory fell to M. Barriaux, who, on a Bolide car with twin-cylinder De Dion engine, scaled the hill in 3 min. 11 1-5 sec., M. Bailleau, on a vehicle of his own construction, being second in 3 min. 49 4-5 sec. The competitors in the class for four-seated cars costing from £160 to £300 included Passy-Thellier, Boyer, Bolide, Chenard and Walcker petrol cars, and a Gardner-Serpollet steam car. The latter, which was driven by M. Vendel, proved the winner, the time being 2 min. 38 sec., M Meyer, on a Passy-Thellier car with Gobron-Brillié engine, being second in 2 min 50 2-5 sec.

Ten cars competed in the class for four-seated vehicles costing from £320 to £480, these including three Aries, two Corres, a Roy, Creanche, Gardner-Serpollet, Boyer, and a Chenard and Walcker. The winner was M. Amand, on the Serpollet steamer, his time being 1 min. 52 sec. The second place was secured by M. Walcker on the Chenard and Walcker (time 2 min. 39 1-5 sec.). A dozen competitors turned out in the class for four-seated cars costing between £480 and £720, these comprising two Richard-Brasiers, two Radias, and a Gardner-Serpollet, Peugeot, Aries, Tony-Huber, Renault, Berliet and Alcyon. The hill-climbing capabilities of steam cars were again shown, M. Pelser, on the Serpollet, making the best time, viz., 2 min. 1 sec., as against 2 min. 13 sec. by the second man—M. Cuchelet, on a Peugeot. Of the cars with covered bodies, M. Barthelemy on a Berliet made the fastest climb (3 min. 28 sec.). There were only two competitors in the class for cars costing between £720 and £1,000, M. Rulot, on a Serpollet, being first in 2 min. 5 2-5 sec., and M. Albert, on a C.G.V., second, in 3 min. 11 1-5 sec. The class for cars costing over £1,400 was competed for by two 60-h.p. Mercedes, that driven by M. de Larentre-Tholosan making the best time of the day, viz., 1 min. 42 2-5 sec., a speed equal to about 35½ miles per hour.

The competition, which lasted from soon after 1 p.m. almost till dark, went off without accident of any kind. The feature of the day was the success of the Gardner-Serpollet steam cars, which carried off the first place in each of the four classes in which they competed.

PUBLIC SERVICES IN ITALY.

A COMPANY has been formed to work a "Diligence" service in middle and southern Italy by motor-cars in place of the horse-drawn vehicles at present in use. After exhaustive tests an order has been given to the Compagnie Belge de Construction d'Automobiles, the makers of the well-known "Pipe" cars, whose representatives in this country are the London Motor Garage Company, Limited, for no less than 600 20-h.p. "Pipe" *chassis*, 300 omnibus bodies, and 300 wagon bodies. The motor vehicles will be so constructed that the omnibus body can be replaced by the wagon body, as occasion may arise, the change from one type of vehicle to the other occupying only half an hour to effect. The omnibuses will each carry ten or twelve passengers, and the wagons about two tons of merchandise. The Italian Government and municipal authorities have given their support and assistance to the motor service in a most practical manner. The roads to be traversed present unusual difficulties, but where awkward corners exist means will be taken to render them easy to negotiate. The Motor Transport Company will enjoy the same privileges as the Italian Railway Companies; there will be fixed stopping places, where only the passenger vehicles will stop to take up or set down. The municipal authorities of each city have agreed to furnish a station, with waiting room. The first service will be inaugurated on January 1st, 1905, and other routes will be arranged as quickly as the vehicles can be manufactured.

A USEFUL FOOT-WARMER.

A USEFUL foot-warmer for use on motor-cars has lately been brought out by Messrs. Desponts and Godefroy, of Levallois-Perret, Paris. It is arranged to be fitted in connection with the piping connected with the circulation of the engine cooling-water. It consists of a flattened copper pipe, the ends of which are beaten and riveted together, and a two-way valve, the latter being fitted on the dashboard, so that the water may be made to circulate through the "chaufferette," as

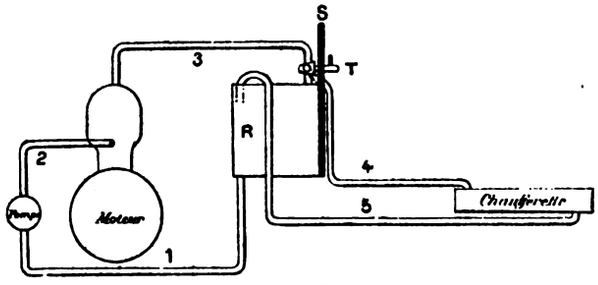

Fig. 1.—Diagram of Connections.

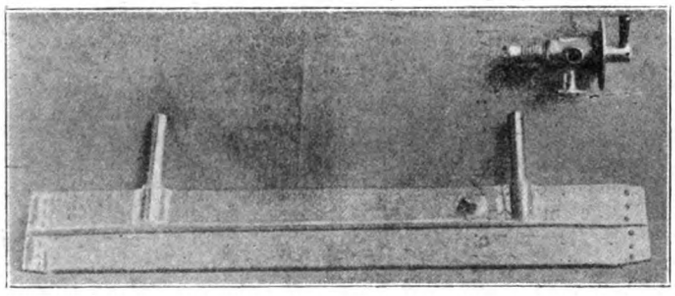

Fig. 2.—View of Footwarmer.

it is called, at will, or shut off when not required. The accompanying diagram shows the arrangement as applied to a De Dion car; it can, however, be readily adapted to any car. As will be seen, in addition to the pipes 1, 2, 3, which form the usual circuit of the cooling water, a pipe, 4, is provided to convey it to the chaufferette, and another, 5, to return the water to the tank. The two-way valve T is mounted on the dashboard, and when the foot warmer is not required the water is made to pass direct into the tank.

THE two Oldsmobile cars were last week put through the most severe test that they have had during the whole of the run, with perhaps the exception of the four days in Ireland, and the letters received from the two drivers have been very different from what they were for the first week or two. They have found their 100 miles a day very trying and difficult, on account of the terrible state of the roads and the fogs. The roads through Cornwall and Devon were beyond description, and, to make matters worse, in mapping out the route for them Messrs. Jarrott and Letts had taken them off the main roads, and they had to get right into some of the country lanes; still, in every case they completed their day's run at the town arranged for them. One day they drove fifty miles through nothing but fog and rain, and they had some very trying experiences, nearly coming to grief on several occasions, as the horses, especially in Cornwall, seemed unused to the sight of motors. The hills were very bad, and the surface was so greasy that the wheels absolutely refused to bite, and then when they had a very fine stretch of down hill, it was impossible for them to let their cars go, owing to the treacherous state of the roads. The run on Saturday was from Exeter to Bath; on Monday, Bath to Oxford; on Tuesday, Oxford to Stamford; on Wednesday, Stamford to Hatfield; finishing in London on Thursday morning.

CYLINDER COOLING.

PERHAPS no one thing in an explosive motor has received so much ingenious attention from designers and constructors as has the keeping of the cylinder in proper condition. To understand some of the difficulty of doing this, one must consider the causes which may increase or diminish the quantity of heat transmitted by the explosion of the mixture to the cylinder walls. In the first place, this quantity varies according to the dimensions of the cylinder, the volume of gas being constant. The loss of heat is practically proportionate to the area of the cylinder walls divided by the volume. There is, however, no proportion between the loss of heat and the number of explosions, since with the increased speed the gas is not so long in contact with the walls and is not cooled to the same extent.

All things being equal, a compression which raises the temperature, without the temperature of the cylinder walls being augmented at the same time, means, remarks Mr. T. Trenholme in the "Automobile Magazine," a greater absorption of heat by the cylinder. There are other causes of absorption, such as bad carburation and the existence of scale or fur in the cylinder head. This latter is often due to insufficient cooling, and should be carefully avoided. In radiating the heat from the cylinder it should be remembered that there is an interest in keeping the temperature as high as possible without decomposing the lubricating oil.

The oils generally employed cannot stand a temperature of more than 350 degrees Cent., and experience has proved that this point is not exceeded by keeping the water at a temperature of 80 to 100 degrees. This is, unfortunately, not the case with the valves, which work best at a low temperature, when they allow of the admission of a larger volume of gas. This seems to imply that the water should enter the jacket round the valves so that they would be sure to get the benefit of the low temperature. Some makers have even eliminated the jacket around the cylinder and contented themselves with circulating the water round the explosion chamber. The same result can, however, be obtained by varying the dimensions of the jacket, but care should be taken to ensure a circulation of water as active and regular as possible. Furthermore, the same water should be used over and over again as a means of preventing the formation of scale or fur, and for this reason the radiator should be designed to avoid any loss of water.

In considering the radiator, it will usually be found that its efficiency depends upon the difference between the temperatures of the air and water, the speeds of the water and air, and the form of the cooling surface. The honeycomb radiator has a greater cooling power than the older form of flanged tubes, but its construction is somewhat delicate.

Some experiments have recently been carried out with regard to the cooling of motors in the laboratory of the French Automobile Club, wherein it was found that when the water entered cold at the bottom of the cylinder there was less power than when it entered at the top. Logically the water should enter the cylinder at its hottest part, that is to say around the exhaust valves, which are always bathed, as it were, in very hot air. The cooling of the valves has a far greater influence on the running of the engine than is generally believed, and it should, in consequence, be given even greater study than it has so far received.

FOLLOWING the note in a recent issue, Mr. G. Goldschmidt, of 323, Green Lanes, London, N., asks us to mention that he was the first to introduce the Merz motor goggle in this market some years ago, and is still the sole agent for the United Kingdom and the colonies. He is supplying these goggles with the new Merz patent interchangeable capsules, which very much facilitates repair in case of breakage of glass or mica. The new catalogue, which we mentioned in our previous note, is now published, and includes also his "Original Doubletwist" and "Octopus" horns, as well as the "Zanardini" headlights.

HERE AND THERE.

THE Derby and District Automobile Club has now a membership of a hundred.

LORD WINDSOR will probably preside at the inaugural dinner of the South Wales Automobile Club in December.

THE Reilloc Tyre Company, Limited, has been registered with a capital of £10,000 and with offices at 122, Victoria Street, S.W.

MR. J. W. LOVEGROVE has taken the management of the tailoring department of Messrs. Alfred Dunhill, Limited, in Conduit Street, W.

MESSRS. W. HANCOCK AND CO., brewers, of Cardiff, are thinking of adopting a two-ton petrol wagon for their bottled beer business.

LORD ONSLOW, the President of the Board of Agriculture, continues his visits to agricultural associations, generally travelling by motor-car.

A MOTORIST who collided with a market cart at Church Stretton has been censured by a coroner's jury for not giving audible notice of his approach by sounding his horn.

ON the 2nd prox. a presentation will be made to the hon. secretary of the Yorkshire Automobile Club, at the headquarters, and on the 25th prox. the annual dinner of the organisation will take place.

MR. A. MEIER is now stocking petrol at Redhill. Being twenty miles from London and thirty-two from Brighton, he is in a convenient position for supplying those travelling from the Capital to the sea.

MESSRS. PETO AND RADFORD'S "Ashtead" accumulators were used by Mr. Archibald Ford on his recent non-stop motor trip. The first 1,500 miles were finished on one accumulator, and the trip of 2,391 miles on a second.

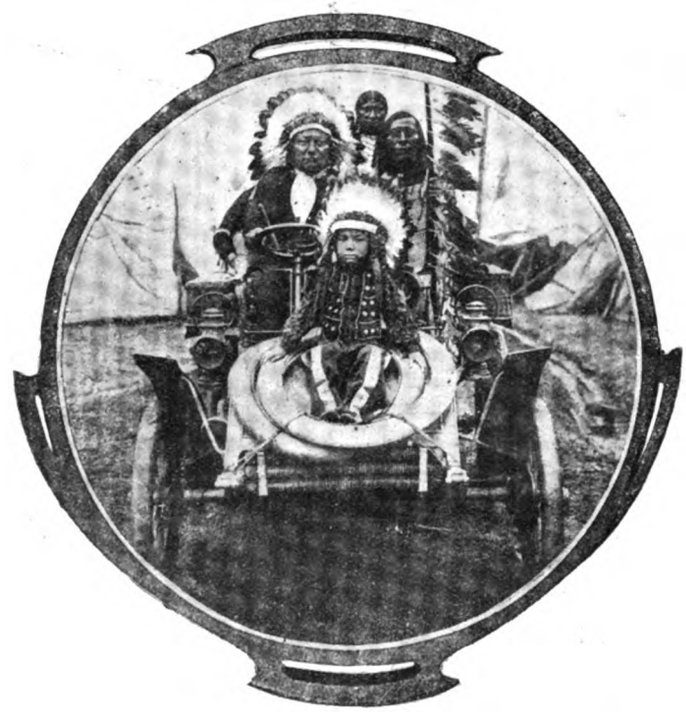
THE IDEN MOTOR-CAR COMPANY has been registered with a capital of £10,000 to acquire the business of motor-car maker carried on by Mr. G. Iden, at Fleet Works, Fleet Street, Coventry, as the "Iden Motor-car Company."

MESSRS. SAVAGE BROS., LIMITED, King's Lynn, have lately completed a steam sanitary wagon for the Folkestone Corporation. The engineer of the borough reports that the vehicle is used for street-watering and does as much work as six horse-drawn watering-carts.

THERE is a possibility of the Automobile Club of Victoria having to postpone its motor race meeting, which was to be held on the 31st October, on the new automobile racing track, at Aspendale Park, near Melbourne, the recent heavy rains having delayed work on the track.

MR. W. P. BURKE, Fethard, co. Tipperary, has recently devised a series of improvements in and connected with the dashboards and foot-boards of motor-cars. His object has been to increase the comfort of the front occupants by sparing them the numerous draughts caused by the side openings and others attributable to the ordinary dashboard arrangements. In his device the effect is gained by diverting the air currents in another direction, by means of a series of simply designed wings made in wood, or light sheet metal. These are affixed to the sides of the dashboard by means of brackets on hinge pieces, which latter may be said to be the only permanent fixtures necessary to attach to the vehicle. The draught screens themselves in no way interfere with the roominess of the car, nor require the alteration of any fitting, lever or controlling device; on the contrary, they add to the lateral width of the car, forming as it were a pair of outside pockets. As arranged for the front dashboard the fitting forms a sort of semi-dome shaped cupboard, suggestive of the type used on Daimler cars, but, being hinged, may be swung flush with the top of the dashboard. The various dashboard fittings, lubricators, clock, gauges, etc., are thus protected from the weather, and their inspection rendered easy by the tilting movement of the dome-shaped cover. The pockets formed by the angle fastenings at the side of the dashboard and the side draught screens form convenient receptacles, or may be used to attach lubricators, carriage clock, and similar light fittings. Judging from the drawings sent us by Mr. Burke, the device seems likely to prove a success and should prove of interest to motor-body builders.

THE Duke of Connaught has so far recovered that he has been able to again go a motoring.



THE King's motor-car was kept at a standstill in Brentford's narrow High Street recently owing to a heavy lorry being slightly ahead of the vehicle.

THE Paddington Borough Council have petitioned the Local Government Board to limit the speed of motor-cars all over London to ten miles an hour.

MR. G. P. RUE has acquired the motor repair business of Mr. C. Wood at Paddock Wood, and is adding an inspection pit to the accommodation for motorists.

THE motor char-a-banc built in Paris for Yarmouth, to which reference was made in a recent issue, has arrived, being driven there by Mr. H. Bateman, the managing director of the Pioneer Cycle Company, Limited, of Great Yarmouth.

THE Palmer Tyre, Limited, are to-day (Saturday) transferring their head offices from Martineau Street, Birmingham, to more commodious premises, Nos. 119, 121 and 123, Shaftesbury Avenue, London, W. The warehouse at Belmont Row, Birmingham, will be retained for the distribution of tyres in the Midlands.

A Sioux Chief and his Family on an unaccustomed spin.

A CLASS for instruction in automobile engineering is about to be started at the West Side Auditorium of the Young Men's Christian Association, New York. The class will be open to pupils desirous of becoming professional chauffeurs, and also motorists who seek to acquire a thorough working knowledge of their cars.

WE learn that Messrs. Brown Brothers, Ltd., are making a speciality of fitting four-cylinder engines in place of two-cylinder engines in the cars of those motorists who desire more power. This work is done at their West End depot, 15, Newman Street, where they have every facility and convenience for doing it promptly and satisfactorily.

MR. E. KENNARD draws our attention to a new motor-horn with reed mouth-piece, which gives notice to careless carters on the wrong side of the road at least a hundred yards further than any horn he has previously used. Another article which he has found serviceable is a petrol gauge, which is soldered flush on the top of the tank. The cork inside the tank, floating on the surface of the spirit, turns an indicator in the little dial, which tells at a glance what amount remains within. Messrs. Dunhill's, Ltd., are agents for these specialities.

Digitized by Google

THE report that the German Daimler Motoren Gesellschaft is at work on an 8–14-h.p. three-cylinder Mercedes car is denied.

THE United States Heating Company is adapting its system of heating buildings by independent generators outside their walls to garages.

MR. W. L. DUCK drove a 20-h.p. Winton car in the speed trials at Blackpool, and secured third place in the flying kilometre test for cars costing under £500.

The Doherty New Pattern Standard Bonnet.

AT the twenty-sixth annual ploughing match of the North Kent Agricultural Association at Dartford, on the 3rd prox., there will be some exhibition trials of double furrow ploughs fitted with agricultural motors.

THE Société des Automobiles Ader, Limited, has been registered with a capital of £12,000, to adopt an agreement with M. L. Duchanoy, and to carry on the business of manufacturers and repairers of and dealers in automobiles, &c.

ASTER, LIMITED, is the title of a company just incorporated and fully subscribed, which has purchased the goodwill, name, and business of the Begbie Manufacturing Company, Limited, and will continue to carry on the business in the same manner as hitherto under the same management. Mr. S. D. Begbie will continue as managing director.

THE Garcin Renault Electric Cars and Accumulators, Limited, has been registered with a capital of £20,000, to adopt an agreement with M. P. Verhaeghe, and to carry on the business of dealers in and factors and vendors of motors, motor-cars, motor-yachts, launches, air ships, accumulators, and other vehicles of all kinds, whether propelled by electricity, steam, petrol, alcohol, gas, or other motive power.

MR. A. BRUCE-MOORE has been appointed agent for the United Kingdom for the Harburg and Vienna India Rubber Co., and has opened a depot at 193, Corporation Street, Birmingham, for the sale of motor-tyres and all kinds of rubber goods. The firm have a patent rim, one side of which is detachable by means of clips, and it is claimed that a punctured tyre can be taken off the rim and replaced in a few minutes.

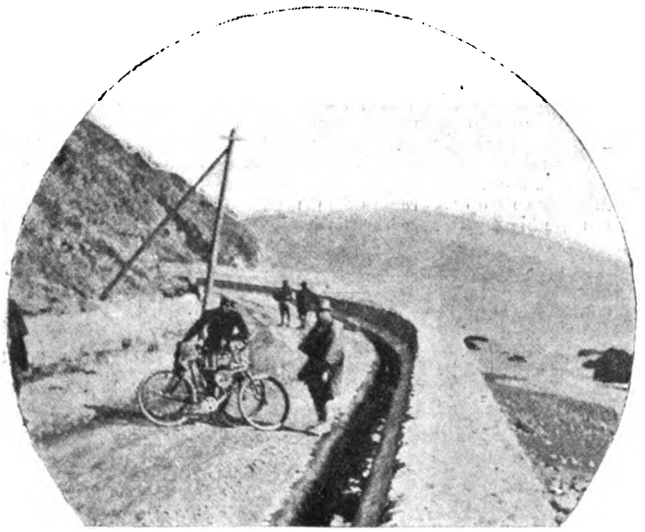
IN rebuilding worn tyres the Glasgow Motor Tyre Co., of 71, Waterloo Street, Glasgow, have attained distinction, and from the section of a motor-car tyre which they have renovated it is clear that they have every facility for doing good work. Their method is to thoroughly strip the old rubber off and replace it with new, rubber of a good quality being used. The company are sole proprietors of the Cassell non-puncturable band for motor tyres.

THE Highways Committee of the London County Council report that from September 24 to October 8 they registered 114 motor-cars and 69 motor-cycles, thus making the total number of cars and cycles registered up to the last-named date 4,585 and 3,147 respectively. The Clerk of the Council has also issued during the same period 122 licences to drive motor-cars or cycles, and general identification marks for motor-cars have been assigned to four manufacturers or dealers, the total number of licences and general identification marks issued being 11,130 and 291 respectively.

IN their latest booklet descriptive of their non-skidding bands, the "Otto-Bennett" Motor Company draw attention to their "Otto" detachable non-skid, which can be attached in less than three minutes, and from its construction it is practically impossible for it to creep or come off. The strength of the tyre is said to be considerably increased, and bursts and punctures are practically unknown in their experience. The See unpuncturable band and the "Stepney" patent wheel for motor-cars also find illustration in the catalogue.

THE Atlas Brass Foundry Co., of Brooklyn, U.S., has during the past few months successfully repaired a number of broken aluminium castings—parts of automobiles—by a new and interesting process. The repairs made have been mostly to gear boxes or engine crank cases, from which a supporting lug had been broken, or in which a crack had developed. In cases of the first kind, if the part broken off is comparatively small, no attempt is made to use the old piece, but new metal is cast on and the original shape of the part restored. To do this, the larger part of the casting is imbedded in sand for some distance from the break, and the smaller piece is used to form a mould for the new metal to be cast on. Molten aluminium, together with a special flux, is then poured into this mould, and is specially treated as it cools. In cases where the casting is cracked, or a large piece is broken off, the method of procedure is somewhat different. Both parts are imbedded in a mould, with the broken edges abutting. The molten metal and the flux are then poured between them, and the cooling process used as in the other case. A perfect continuity of metal from the old part to the new is said to be obtained in this manner, and it is impossible to tell, even by cutting into the metal, where the old metal stops and the new begins.

THE accompanying illustration shows a portable work bench and tool chest adapted for use in connection with the repair of motor-cars, which has lately been brought out by Messrs. Thos J Syer and Company. As will be seen, it comprises a complete repairing outfit for a motorist or motor repairer, and in addition a bench to work upon. It can be wheeled to any point, and the



necessary repairs made on the spot, thus saving much valuable time. The bench can also be used in the workshop as an ordinary table, and the tools can be kept under lock and key when not required for use. The bench top measures 3 ft. 6 in. by 1 ft. 10 in., while the tool chest is 2 ft. 6 in. long. The combination is fitted with screw bench stop, locks and keys for tool chest, an engineer's vice, and all necessary fittings and tools to customers' requirements.

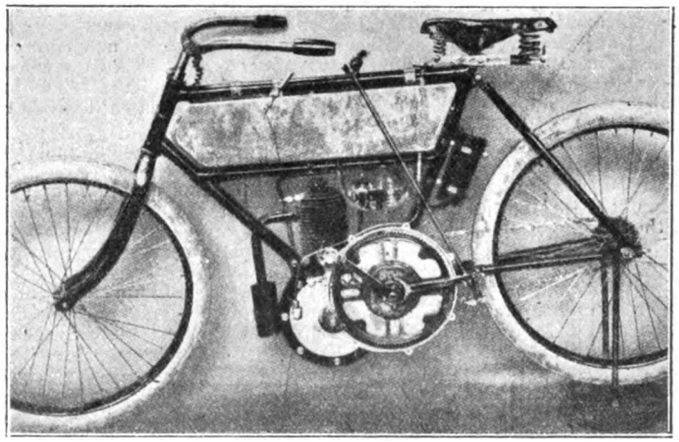
Digitized by Google

MOTOR CYCLING NEWS.

On Saturday next, the 5th prox., the Automobile Cycle Club will hold a reliability trial for motor-cycles designed to carry two passengers, fitted with change speed gears and costing under £100. The start will be from either Barnet or Hatfield and the route probably through Hertford, Royston and Newmarket.

Motor-Cycling in Japan. On the way to Fusiyama.

The Coventry Motor-cycle Club have decided to continue the Saturday afternoon runs for the next three months by arranging a country headquarters at the Duncow Hotel, Dunchurch. An attendance book will be kept at the hotel, and members should insert their names on the outward journey, stating which route they have taken and the time they expect to return. By this means those who do not wish to extend the journey may know that they will have company at teatime and on the return journey. Mr. W. Grew, or a member of the committee, will leave the L. and N.W. railway arch on the London Road, Coventry, every Saturday at 2.30 p.m.



The Birmingham Motor-cycle Club have recently held a competition, the finish of which took place on Saturday. A flat bye road near Erdington was marked out as a starting and stopping course. This consisted of about a third of a mile, with two lengths of twelve feet, at equal distances, within which the competitors were obliged to bring their engines and road wheels to rest and restart. This distance was covered against the watch, making three starts and three stops, this proving a very fine test for the brakes. The times were:—Mr. Downing, 1 min. 15 3-5 sec.; Mr. Winckle, 2 min.; Mr. Thompson, 2 min. 30 sec. Mr. Downing was declared the winner of a three-guinea prize.

The "Adaptable" is the name of a new driving belt for motor-cycles which has lately been put on the market by Messrs. S. Rawlings and Sons, Limited, of Frome. The new belt, instead of being made of two or three continuous strips of leather fastened together, is built up of a series of short lengths of leather connected together in a simple manner and in such a way that a short tongue projects every few inches on the under-side of the belt; the tongue wedges itself in the V-groove of the pulley and so prevents the belt slipping, while allowing it to leave the pulley freely when it has completed its circuit. It is claimed for the new belt that it is exceedingly pliable, and that, owing to its gripping powers, it can be ridden slacker than usual. It is also easily shortened when necessary.

Messrs. Crudginton, Kennedy and Co., Birmingham have brought out a new belt fastener known as the "Flexo," designed by Mr. J. T. Flood, of Dublin. The device is of the hinged-plate type with a threaded wire for each hinge, one end terminating in a looped joint, through which the pin which couples the hinged plates together passes, the other or free end terminating in a screw, bent at right angles, and passing through a hole in the end of both plates. The latter being of a short length, the belt may be readily bent over even a small pulley without straining the fastener, this being also facilitated by the holes in the plate being larger than required to fit the screwed wire. The method of attaching the fastener is very simple; the plates are merely laid over the top of the belt and a hole punched to meet the one in each. The free end of the binding screw is then passed through from the under side of the belt and screwed taut.

The Manchester Motor Club held its first hill-climbing competition on Saturday last. The event was confined to motor-cycles and fore-cars, and was in the form of a handicap. The course was on the mountain road up to the "Snake," on the borders of Derbyshire, about fifteen miles from Manchester, the starting-point being a mile and a half from Glossop. The course measured about a mile and a half. There were twenty-two entries, of which eleven competed. The men were sent off at two-minutes intervals, fifty yards behind the starting line, up to which they were allowed to pedal, but not beyond. The best time was made by H. Andrew, who, on a 3¼-h.p. Fleet, with 10 sec. start, made the climb in 2 min. 59 2-5 sec.

A new motor-bicycle which is at present attracting much attention in France is the "Magali," made by Messrs. Gaillon and Co., of Levallois, near Paris. The feature of the machine lies in the system of transmission. As will be seen from the illustration, the power of the engine is conveyed through a small pinion on the engine shaft to a large toothed wheel running loosely on the bottom bracket spindle. Combined with the wheel is one-half of a leather-laced cone clutch, which by a lever, controlled from the top bar of the machine, can be made to engage with the female part of the clutch, also mounted on the bottom bracket spindle, from which the engine power is transmitted to the rear wheel by the usual pedalling chain. The illustration shows a machine fitted with an engine of 1¾-h.p. and weighing only 88 lbs., which is, owing to the direct transmission, claimed to

be able to attain a speed of forty-four miles per hour on the level and to mount all ordinary hills without pedalling.

The Sheffield Automobile Club will meet to-day (Saturday) at Beeley, beyond Chatsworth Park, at 4 p.m.

Further evidence of the resiliency of the Palmer Cord motor tyre was afforded by the fact that the fastest time in the racing class for the flying kilometre at the Blackpool Speed Trials was made by the only car—the Napier driven by Mr. Clifford Earp—fitted with Palmer tyres.

CORRESPONDENCE.

THE BLACKPOOL SPEED TRIALS.

To the Editor of *The Motor-Car Journal.*

Sir,—In the interests of the steam car and its advocates, we wish to bring the following facts to the notice of your readers. Two Gardner-Serpollet steam cars were entered by us, under their respective selling prices, for the speed contests at Blackpool. The entry and fees were duly acknowledged by the secretary, but, four days before the race we were advised by telephone that these cars would not be permitted to compete with the petrol cars, as they were reputed to be able to gain greater speeds than the latter. We pointed out to the secretary that the classification was by price, and that there was no mention of the events being restricted to petrol cars, and it was obvious that one of the objects of the race was to find out the fastest car at a given selling price, and we could not see any reason why the Serpollets should be debarred from running, but nevertheless the committee remained firm, and our cars were not allowed to compete. As the races at Blackpool were classified under selling prices, we cannot see any just or reasonable explanation for debarring our Serpollet cars from competing, and we hope at future race meetings the committee will not again place these cars under a ban, but allow them to stretch themselves in a race against petrol cars selling at the same price.—Yours truly,

J. W. H. Dew.

To the Editor of *The Motor-Car Journal.*

Sir,—Will you allow me, through the medium of your valuable paper, to say a few words about the motor speed trials at Blackpool? It seems a pity that these trials are not entirely organised and carried out by a committee of Blackpool or other gentlemen who are unbiassed and who would act fairly in the matter to all cars alike. I was looking forward to this meeting and had arranged to enter two cars in some of the events. On the official programme and entry forms there was absolutely no stipulation whatever against the steam car, and yet two days before the races commenced I was informed that steam cars would not be allowed to run. I take it the Blackpool people and general public want to see the fastest car win, and it really seems extremely unfair that such excellent motor-cars as the White, Stanley, Turner-Miesse, and Serpollet should be prevented from running.—Yours truly,

Fair Play.

REPAIRS IN DUBLIN.

To the Editor of *The Motor-Car Journal.*

Sir,—In a recent issue of your paper you print an extract from an article written by Dr. Abbott, of Tunbridge Wells. As this reflects upon my capacity as a motor repairer, I beg to give you the facts of the case. The doctor drove his De Dion car here and requested that his expanding clutch be adjusted. My foreman expressed regret that he could not put a man on to it just then, at which the doctor became choleric, declaring that if he had the facilities he would do the work in ten minutes. Thereupon my foreman placed my garage and tools at his disposal, and the doctor and his friend put in a good two hours' struggle with the refractory clutch, which latter finally came out victorious, having eluded the doctor's best attempts at bringing it back to working order. One of my men put it right when he took it up late that night. The doctor misrepresents the facts when he suggests that at least six of my men had a try at it.

During the time he was in the garage I passed through, and Dr. Abbott complained to me rather furiously of the De Dion agent's business methods. (Most people are furious at the end of an unsuccessful two hours "set-to" with a motor-car.) I explained that the firm were new in the business, only sold the cars, and did not pretend to be repairers. I added that he could, however, safely leave his car with my men, as they executed repairs for His Excellency the Lord Lieutenant.

Of course it must have been to introduce a spice of humour and fun that he quotes me as addressing him "Sure Sor" and "Oireland." These are good things to tickle an Englishman's fancy, and he catered accordingly for his readers in "The Kent and Sussex Courier." "Sor" does not exist in any brogue, and "toimes" and "Oireland" are a pure East Endism, as the doctor knows well, for did he not come to Dublin in his youth to receive his education? I can understand Dr. Abbott being as he was at the time, irritated, but I submit it was churlish, not to say libellous, to recount his experiences to my prejudice. Apologising for troubling you with so lengthy a communication.—Yours truly,

Dublin. J. J. Keating.

GEAR TROUBLES.

To the Editor of *The Motor-Car Journal.*

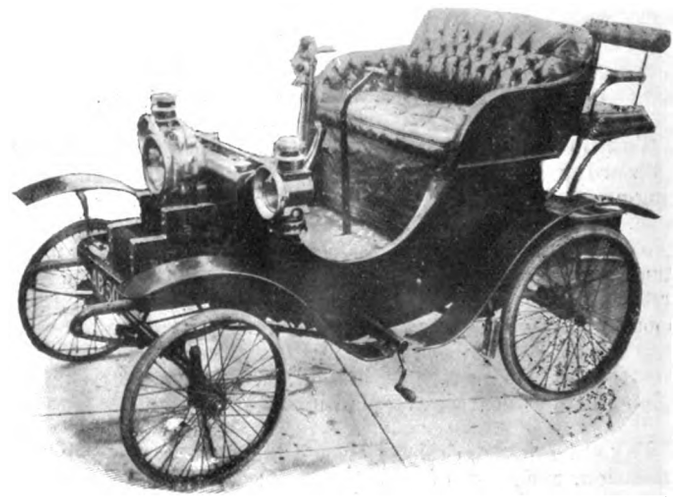
Sir,—I have just read "F. W. B.'s" letter in the last issue of the *Journal.* This appears to me to be a case of trying to change gears without first releasing the clutch, which would, without doubt, soon wear the gears out. In some cases the first gears are found to be difficult to get in, especially when the car is stationary, owing to the clutch continuing to run, but this difficulty can easily be overcome by fitting a small block for the clutch to rub against when the same is released. With regard to the second and top speeds, these ought to cause no trouble if the clutch is first released. The most reliable way to caseharden gears is by means of a muffler, which is filled with scraps of leather and bone dust. The work to be hardened is placed in with this, a lid put on, and the whole kept at a blood-red heat for several hours, according to size of work and depth to be hardened; after which the work is cooled off either in water or oil.—Yours truly,

Expert.

THE REPAIR OF ROADS.

To the Editor of *The Motor-Car Journal.*

Sir,—I wish through your columns to protest against the way in which trenches dug across the road are filled in, making a huge ridge that must be a source of danger and discomfort to all users of the road. Only last Wednesday night, coming from Coulsdon on to Purley, I ran across a ridge of this description just made. My car, being a small one, pitched very badly and shot both my passenger and myself right out of the seat. It was a wonder the springs of the car were not broken; but fortunately, so far as I can discover, a badly bent chain stay is the only damage done.



A correspondent of yours recently suggested the making of these ridges in order to stop "scorchers," but it seems to me the small cars suffer more than the big ones from inequalities in the road surface.—Yours truly,

4½ H. P.

LEVER STEERING.

To the Editor of *The Motor-Car Journal.*

Sir,—As you suggested in a foot-note to a letter of mine some months past, I now send a photograph of my car fitted with rather an unusual form of lever, as an experiment. It is quite successful, and far preferable to a wheel in ease of control, and is easy of access to seat. This is the second

car from which I have removed wheel steering and fitted lever instead. The upper end of the lever is 28 inches long, and the lower end below pivot is six inches. Tested by spring balance a pull of six to eight pounds will send the wheels right over, when car is standing on a stone pavement. Will anyone test the pull required by ordinary wheel steering? I think it will be found to require considerably more than this.

Any form of lever steering, combined with inclined wheel pivots, would be much more comfortable for small cars than the wheel, and would be non-reversible, without special fittings as required by wheel, and therefore cheaper to make?—Yours truly,

A.B. 50.

RELATIVE SPEEDS OF MOTOR-CARS.

To the Editor of *The Motor-Car Journal.*

Sir,—It has frequently been discussed what are the uses in this country for high-power motor carriages, and to what extent such cars can be utilised on the roads of England.

During the past week I had an interesting demonstration as to what extent a motor-car of 60-h.p. is superior in speed to a car of one-half this horse-power. I was a passenger on a Mercedes car of 60-h.p. on a run of 290 miles to London; the other car which was engaged upon this run was a 28-h.p. Crossley. The latter car started five or six minutes in advance of the higher power car. An early start was made, so that London could be reached the same evening. When the cars started the roads were very wet, and there was a continuous drizzle; however, after the first ninety miles the weather cleared and everything was in favour of good running, the roads being in perfect condition. There was no element of a race between these two cars, but both were driven by expert, reliable, and careful drivers. Being on the much more powerful car, I was under the impression that we should very quickly pick up the Crossley car; however, it was not until 200 miles had been covered that we came in contact with it, when we found the passengers just on the point of completing their lunch. It may be stated that both

Digitized by Google

cars pulled up on the road in the morning for half an hour, for the purpose of replenishing the petrol tanks at different points of the journey. The ultimate destination of the two cars was in close proximity in the West of London, where both arrived within five minutes of each other. Of course, there is no question as to which was the speedier of the two cars, but this interesting run goes to prove it is only possible on English roads to gain a very slight advantage, if any, in average speed on a day's run with any power above 30-h.p. I can vouch for the 60-h.p. car being driven at its utmost speed, having regard to the nature of the traffic on the road. No stops were made by either car on the road, except for the purpose above-named.—Yours truly,

J. S. CRITCHLEY.

BELT TRANSMISSION.

TO THE EDITOR OF *The Motor-Car Journal*.

SIR,—As one of those motorists who have a hankering after a good belt-driven car, on account of the simplicity of the same and small cost of upkeep, I was very interested in Mr. C. Dent's letter in the *Journal* of the 15th inst. and the separate specially illustrated description of his belt-race cone system of transmission. It would be interesting, I am sure, to those of your readers who are not mechanical enough to see the weak spots in this method of transmission, if somebody who is an engineer would point them out. Mr. H. Cove in your issue of the 22nd inst. also gives a very interesting account of a belt-driven car he has. It would, I am sure, be also interesting to your readers if Mr. Cove would inform us where such a car as he has can be obtained, and the probable cost, number of speeds, power of engine, and the make and width of belts used, also a minute description of the novel belt adjustment he mentions. V388

A good method of belt transmission would, I think, do a great deal to popularise motoring with the man of moderate means, on account of the smaller initial outlay, economy in upkeep, ease of change from one speed to another as compared to gear-driven cars, etc., absence of noise, etc.—Yours truly,

LANCASTRIAN.

TO THE EDITOR OF *The Motor-Car Journal*.

SIR,—The correspondence on this subject has been most interesting, but I am rather surprised at the lack of criticism on the part of those who run down belt drives. The invention of Messrs. Dent, in your issue of the 15th inst., has a formidable list of claims, which, if maintained, would easily give this neglected drive a place again. I am not an expert, but should like to hear what such have to say on the matter. Such possibilities in belt transmission as would appear from this correspondence, and particularly that in the *Journal* of the 15th inst., by all means ought to be speedily available. If, on the other hand, those who know can finally urge such objections as will condemn it, let them give them.

Such points as extreme simplicity, mechanical correctness, small upkeep, etc., are those that business men in particular appreciate.—Yours truly,

J. B.

QUERIES FROM SOUTH AFRICA.

TO THE EDITOR OF *The Motor-Car Journal*.

SIR,—In your issue of September 3rd I notice in a letter written by "A. H. 59" he says he has used stout bands on the wheels of his Locomobile and had no punctures. I am also the owner of a similar car with 28 in. wheels and single tube Diamond tyres. Would "A. H. 59" kindly inform me, through your paper, the name of the maker of these bands and where I can procure them?

I am just now expecting a Model B Cadillac car, and shall later let you know how it behaves on our South African roads and under our summer sun.

These light car trials now going on are very interesting to all intending motorists out here, and have already, to my mind, demonstrated how few really reliable hill climbers there are among the legion of different makes, and should do more to enable correct choice than anything yet tried.

Can any of your readers tell me if the motor-bicycle is yet built that will take a passenger up Frome's Hill; if so, name and horse-power?—Yours truly,

South Africa.

G. C. WILLIAMS.

LIGHTS ON VEHICLES.

TO THE EDITOR OF *The Motor-Car Journal*.

SIR,—Having read a paragraph in the *Journal* asking readers to report on accidents caused by vehicles improperly lighted, I send the following incident. A few nights ago a friend was riding a motor-bicycle, to which a side-car was attached (empty), along the road between Ashtead and Leatherhead, when he noticed a light some distance ahead, and he steered, as he thought, to clear the object, when to his surprise he ran into it. It turned out to be a traction engine, and was standing still on the off side of the road with the only light on the near side, giving one the impression that there was sufficient room to pass. There was barely three feet between engine and bank. It smashed the front of the side-car and bicycle. The rider was fortunate to escape with a severe shaking, causing him to be kept from work for two weeks. If he had not been well acquainted with the road he must have been killed. I was informed that the driver was sitting in front of the engine fire warming himself.—Yours truly,

A CAREFUL DRIVER.

EXPERIENCE WITH THE REXETTE.

TO THE EDITOR OF *The Motor-Car Journal*.

SIR,—Would any of your readers give their experiences in regard to the Rexette, as I am thinking of getting one of these little cars? I would like to know something of its hill-climbing powers, speed, petrol consumption, or any other detail that would be of any use to a beginner. Mine is a very hilly district.—Yours truly,

A REGULAR READER.

THE RULE OF THE ROAD.

TO THE EDITOR OF *The Motor-Car Journal*.

SIR,—I see in your comment on the accident to the Duke of Connaught you put the entire blame on the cart, which was admittedly on its right side of the road, for being without lights. It is quite evident, and perfectly clear to me, that the accident would not have happened at all had the driver conformed to the rules of the road. It was simply his wilful transgression of these, in attempting to pass the tramcar on the off-side, which was the cause of the regrettable accident. How long will it be before motorists and also cyclists will understand that the ordinary rule of the road "to pass vehicles which are being overtaken on the right-hand or off-side" *does not* apply to the passing of tram-cars which run on fixed rails. The only side on which trams should be passed is on the near-side, between the car and the kerb of the footpath. The sooner this is learnt as a general lesson by all road-users, the better for everyone. There will surely, sooner or later, be a most serious accident if motorists will persist in defying the rules of the road and passing trams on the off-side, and so putting themselves in the best possible position to be smashed into by an oncoming tram or other vehicle, or running down something themselves.—Yours truly,

COCKNEY.

ALTERING A DE DION CAR.

TO THE EDITOR OF *The Motor-Car Journal*.

SIR,—Will somebody kindly inform me how to alter a 4½-h.p. De Dion car so as to place the engine in front, put in tiller steering and actuate the gears and reverse by foot pedals? A detailed reply would greatly oblige—Yours truly,

R. N. P.

STEAM CARS.

TO THE EDITOR OF *The Motor-Car Journal*.

SIR,—Unfortunately, there is still a prejudice against steam propelled cars amongst a certain class. The performances of petrol cars are usually chronicled fully, but, as a rule, the performances and successes of steam cars—when, as is very rare, they are given a chance of competing on equal terms with petrol cars—are practically ignored, or passed over without comment. Why should not steam cars be allowed to compete with petrol cars in hill-climbing competitions or in speed contests, like the one recently held at Blackpool? I take it that hill-climbing and speed competitions are held to select which cars are the best for those purposes, and I entirely fail to see why steam cars should not be allowed to compete with petrol cars, or why they should be relegated to a class of their own, and compete merely with one another. At Blackpool last week I heard a good many enquiries as to why there were no steam cars running, and I think very few of the motoring public had any idea of the reason, which was that, by the decision of the committee, no steam cars were allowed to compete in any of the classes with petrol cars.

The steam car industry, if it is given a chance, bids fair to return to its old prosperity, and I think the public might be reminded of some of the recent successes of steam cars, such as—1. The wonderful success of the Stanley in the Mount Washington Hill climb. The small Stanley made faster time than any other car entered, doing the distance of eight miles of steep rugged road in 31 min. 45 sec., the previous record being about 50 min. 2. The great success of the Turner-Miesse steam cars at the recent open hill-climbing competition held at Bridgnorth under the auspices of the local Automobile Club, when all three 10-h.p. Turner-Miesse cars entered made faster time than any petrol cars entered of anything like equal power. 3. The all-round win of the White cars in the hill-climbing competition held by the Herefordshire Club, when White cars gained first, second, and third places, and altogether scored a great success.—Yours truly,

A STEAM CAR ENTHUSIAST.

TO THE EDITOR OF *The Motor-Car Journal*.

SIR,—If your correspondent "W. T. Warne" is in the London district, I should be very glad to see his Locomobile, and show him my Weston, which I have had in use two years. I find the throttle as fitted in these cars very troublesome at high pressures, it being sometimes almost impossible to prevent the engine racing, and I am sure a screw-down valve is better if it can be easily fitted. Your correspondent "G. K.," who met with such disaster over his needle valve, should surely have known that

Digitized by Google

one revolution is usually sufficient to open such a valve. All the American made valves I have seen come right out, but there is always a fairly long thread on the stem requiring many turns to bring it out.—Yours truly,

E. F. CALLAND.

THE HORSE POWER OF PETROL MOTORS.

TO THE EDITOR OF *The Motor-Car Journal*.

SIR,—I have been much interested in the various letters on this subject which have appeared in recent issues of the *Journal*. The whole question of motor power is one which has been treated in an unfortunate manner from its commencement, and even the ill-named unit by which it is commonly measured has proved a fertile source of misconception. It is easy, of course; to fix a calculated output for a given size and type of motor, and allow no engine to leave the workshop unless it reaches this standard in a workshop test; and, provided the standard is high enough to ensure the best of workmanship and adjustment, this is, perhaps, the most legitimate use of the definition. But "horse-power," according to this, does not provide the information which the average purchaser desires; in the first place, his engine will seldom work up to its workshop standard, if high, or may improve with use, if low, and also, whereas he would like to be able to roughly estimate the qualities of his car by a horse-power weight ratio, the omission of the question of transmission efficiency makes this impossible. Secondly, the extent to which the construction of the engine permits the normal speed to be exceeded will cause wide differences in the actual performance of engines having equal b.h.p. according to this test at the normal speed. The practice, frequently adopted, of listing engines at anything from 10 to 42 per cent. below their actual maximum power has led to hopeless confusion, increased by the few makers who state the actual average power as nearly as possible, or, following cycle-motor practice, list them at something rather more than any driver will ever get out of them. It is difficult to suggest a remedy, unless it were that, now that most motors are fairly well-designed, cylinder capacity should be quoted for comparison.—Yours truly,

T. C. PILKINGTON.

A COMMERCIAL TRAVELLER'S MOTORING EXPERIENCES.

TO THE EDITOR OF *The Motor-Car Journal*.

SIR,—During the past six months I have been running a 6½-h.p. Coventry Humberette on my journeys throughout the Midland Counties, and have found it not only a very pleasant means of travelling, but also more economical in time, especially to such towns as Leicester, Burton-on-Trent, Redditch, and Nottingham, which places are slow of access by rail. Another advantage is that one can start as early as one chooses, and on the return journey need not consult a time table. The expense of running a reliable small car is comparatively small, as something like thirty to thirty-five miles can be covered on a gallon of petrol, and although to date about 3,000 miles have been covered, the car is in even better condition than when new, as all the parts have been thoroughly tested, and the engine is in freer working condition. Beyond ordinary ignition troubles and a few punctures, very little has occurred to mar the pleasures of motoring, and it is only a question of a little experience and confidence for scores of travellers similarly situated to adopt the motor-car for their journeys.

Another class of men who are fast joining the ranks of motorists are retired tradesmen and business manufacturing men of moderate means, who, having plenty of time on their hands, fill it up by admiring, cleaning, and driving about at their leisure. Hitherto, the obstacle in the way had been unreliability, but this cannot now be made an excuse.

Going back to the car under consideration, it has proved to behave admirably in crowded thoroughfares, being fitted with all the necessary levers and points for perfect control in traffic. It is very free from side-slips; in fact, has never shown a tendency in that direction, although on several occasions it has been driven over miles of greasy tram lines and setts in the Birmingham streets. There is ample brake power for the steepest of hills and cases of emergency. It has sufficient power to climb gradients of 1 in 5, and can usually get up all ordinary hills on the top speed.

On the level a shade under thirty miles per hour can be attained, although I seldom drive above the legal limit, as, from experience, I consider that a small car can be over-driven, and prefer to use the extra power for hill-work. For a single cylinder the car is comparatively quiet, and, owing to the body being well sprung, is very free from vibration. I have had a few special parts added to the car, such as Doherty's transverse tubular radiator, which has so far not given one moment's anxiety. As to tyres, I have been running a pair of Clipper Continentals on the back wheels, and Palmer cord tyres on the front. The distance of 3,000 miles, however, has made little or no difference to their appearance, as they are practically free from cuts, and show very little sign of wear.—Yours truly,

MIDLAND COMMERCIAL.

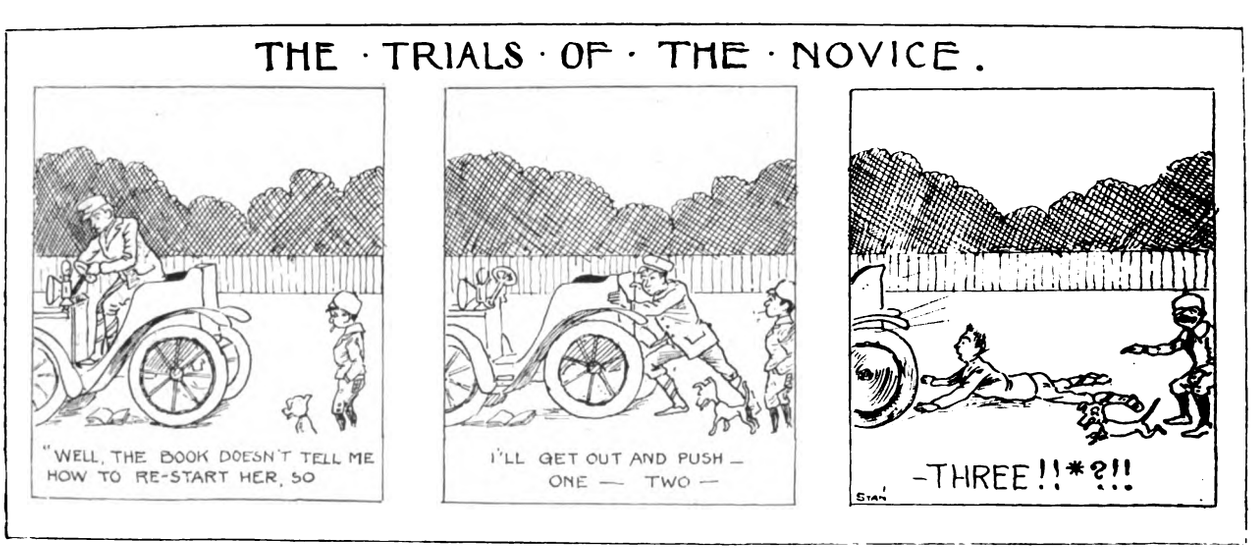
THE BLACKPOOL SPEED TRIALS.—The Speedwell Motor and Engineering Company, Limited, have sent us a long letter in reply to that from the Duryea Motor Company relating to the disqualification of the latter's 10-h.p. car. They state that they quite fail to see why "the protest of Messrs. Carter and Horsfall, the Anglo-American Motor Company, and ourselves should not in fairness have been upheld. The Duryea Company are certainly incorrect in the statements embodied in their advertisements, wherein they announce that they beat our 10-h.p. car by 400 yards. Unless Mr. Sturmey did his own timing, we cannot see how he can arrive at this figure; the official times are certainly not used. The Duryea Company also state that they have made better times than any of the cars under Class D. A reference to the official times will at once prove this incorrect."

STARTING HANDLE FOUND.—Mr. C. Botwright, 7, Whitfield Road, St. John's, Tunbridge Wells, has found a starting handle on the road between Hailsham and Eastbourne, which he will be pleased to return to the owner.

PUNCTURE PROOF BANDS.—In reply to the inquiry of "Irish" in our issue of the 1st inst., Mr. E. F. Cotterall writes commending the Wilton-Cox puncture proof bands.

IGNITION TERMINALS.—In answer to several correspondents, the ignition terminals illustrated in a recent issue of the *Journal* are made by the Chater Lea Manufacturing Company, Limited, 114, 116, 118, 120, Golden Lane, London, E.C.

GEAR TROUBLES.—Messrs. Friswell write in reply to "F. W. B.," to the effect that this is the first "we have ever heard of trouble with the gears of a Baby Peugeot, and that out of over five hundred of these machines running about they have never heard such a complaint before." If "F. W. B." will kindly communicate with them they will see what his trouble is, and put the matter right.



POLICE TRAPS.

AT Chipstead, near Reigate, a police trap has been established in which several motorists have been caught.

THE District Council of Beckenham has been considering the speed of automobiles passing through its streets, and the police will probably be incited to action.

THE Surbiton police trap is again in active operation. It is located in the Portsmouth road.

IN the High Street, Chiswick, the police have a measured furlong.

THE HORSE-POWER OF PETROL MOTORS.

By Captain C. C. Longbridge, M.I. Mech. E.

The indefinite rating under which petrol motors are sold is no doubt responsible for the numerous formulæ devised for rapid computation of their horse-power. Admittedly, such formulæ cannot be more than approximate in application; but the point is, which, if any, are sufficiently accurate to be of practical value. Without special selection, the following motors are taken, and to test the question various formulæ are stated and applied :—

Make.	Number of cylinders.	Dimensions.	Revs. per min.	Piston speed.
		Bore. Stroke.		
7½-h.p. Wolseley ...	2	4in. × 4in.	750	500
25-h.p. Maudslay ...	3	5in. × 5in.	800	675
18-h.p. Star	4	4in. × 4·5in.	800	607

The examples instanced are :—

(*a*) An American formula, devised, it is believed, by Mr. E. M. Roberts, of Clyde, O., U.S.A. :—

$$\text{H.P.} = \frac{D^2 \times L \times R}{C} \times N.$$

(*b*) A second American formula, deduced by Mr. Duryea, from comparisons of 73 American and 22 foreign car motors :—

$$\text{H.P.} = \frac{D^2}{3} \times N.$$

As standard piston speed for the formula, 750 ft. per minute is taken.

(*c*) A third American formula, given by Mr. A. L. Clough, based on American practice, in the case of 22 horizontal motors of various makes :—

$$\text{H.P.} = \frac{D^2 \times L \times \cdot7854}{20} \times N.$$

In the above formula—

D = piston diameter in inches,
N = number of cylinders,
C = a constant; 18,000 for Otto cycle, and 13,500 for two-cycle motors,
L = length of stroke in inches,
R = revolutions per minute.

(*d*) A French formula, by M. Hospitalier :—

$$\text{H.P.} = \frac{r^2 \times l \times R}{1000 \times 75} \times N.$$

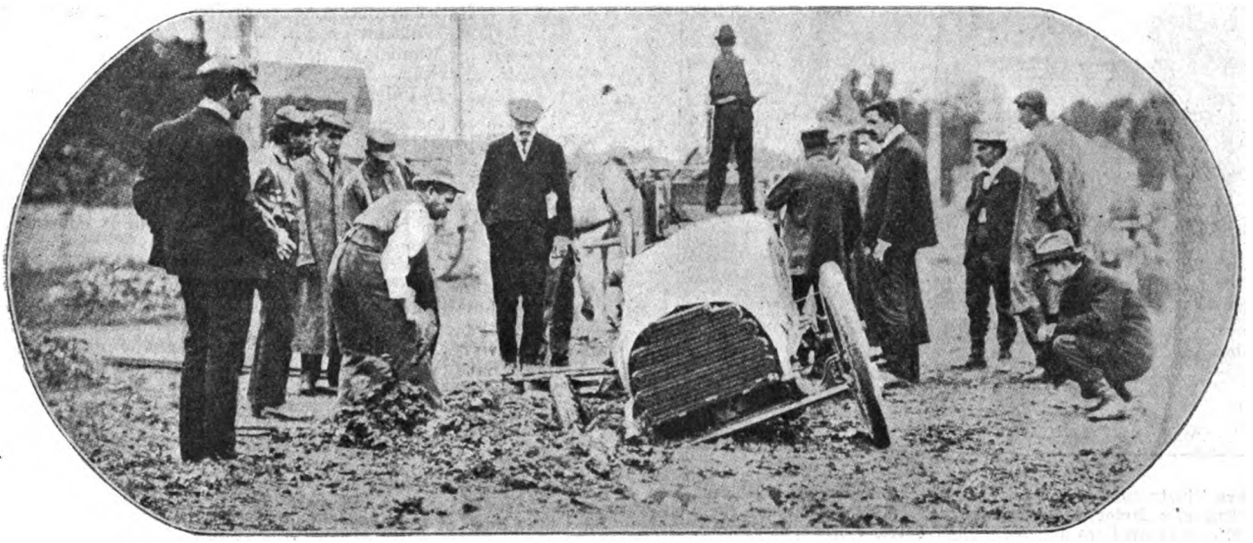
Where r = radius of bore in centimetres,
l = length of stroke in centimetres,
N = number of cylinders,
75 = 75 kilogrammes,
R = number of revolutions per minute.

(*e*) An English formula, suggested by Mr. Nesbitt, and adopted by the Marine Motor Association :—

$$\text{H.P.} = \frac{A \times S \times R}{C} \times N.$$

Where A = area of bore in square inches,
S = length of stroke in fraction of a foot,
C = a constant; 1000 for Otto cycle and 600 for two-cycle motors,
N = number of cylinders,
R = revolutions per minute.

Applying these formulæ, and summarising results in tabular form, the computed horse-power of the various motors are :—



Motor.	As rated by maker	As computed by formula.				
		Roberts.	Duryea.	Clough.	Hospitalier.	Nesbitt.
	H.P.					
2-cylinder Wolseley	7½	5·33	10·66	5·03	5·24	6·22
3-cylinder Maudslay	25	16·66	24·99	14·72	16·38	19·63
4-cylinder Star ...	18	12·8	21·32	11·28	12·54	15·00

It can scarcely be said that the results, as a whole, come within the limits of practical approximation. Is this due to the formulæ or to incorrect rating? An answer is supplied by applying the formulæ to a motor, of which the correct rating is known to the writer, namely, the four-cylinder Daimler, 4·13 in. diameter by 5·11 in. stroke, giving 22 horse-power at 750 revolutions per minute. Calculated by the above formulæ, the horse-power would be :—

Motor.	As rated by maker	As computed by formula.				
		Roberts.	Duryea.	Clough.	Hospitalier.	Nesbitt.
	H.P.					
4-cylinder Daimler..	22	14·52	22·74	13·76	14·16	16·86

The only formula giving, in individual cases, approximately correct results is the Duryea. But, if applied in general, the results bear out the conclusion that, with petrol motors, horse-power computation by formulæ is entirely fallacious.

It may be asked, why cannot steam engine formulæ be applied? No doubt they could, but for one unknown quantity—the mean effective pressure. In the case of the steam engine, this is determined by the cylinder pressure; but in the internal combustion motor it is governed by the design of the engine itself. In the latter, the mean pressure depends on many factors—compression, ignition, temperature of cylinder walls, valves, speed, back pressure, etc.; and petrol motor designing is not yet sufficiently standardised to furnish a mean pressure figure applicable to all motors. Probably from 83 lb. to 85 lb. per square inch represents a figure common to a large number of petrol motors, and if any formula is employed, closer results would, in general, be obtained

An Incident of the Vanderbilt Cup Race.—M. Clement's Racer Partly Sunk in a Mud Hole on the Road from New York to the Cup Course.

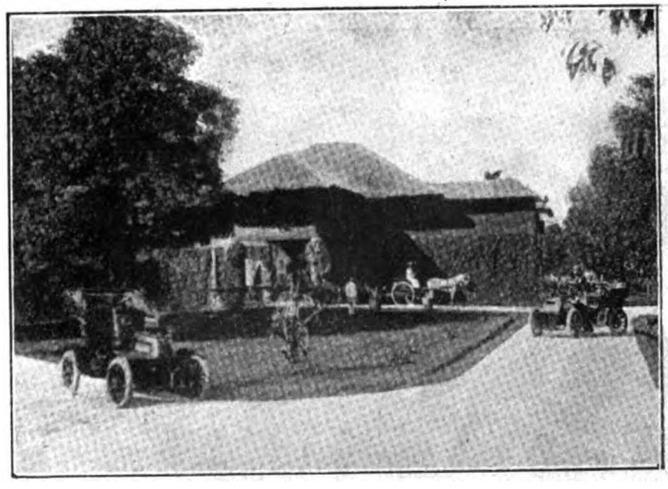
Digitized by Google

by the use of an equation embodying this figure. Taking, for instance, 85 lb. as mean pressure, and utilising the formula :—

$$H.P. = \frac{A \times S \times P \times \frac{R}{2}}{33{,}000} \times N.$$

Where A = piston area in square inches,
S = stroke in fractions of a foot,
P = mean pressure in pounds per square inch,
R = revolutions per minute,
N = number of cylinders,
the horse-power of the above motors work out as :—

7½-h.p. Wolseley	8·07
25-h.p. Maudslay	25·20
18-h.p. Star	19·30



Piston displacement is also frequently used as criterion for rapid calculation of motor horse-power, and various figures are given :—

(*a*) Mr. Duryea allows 15½ cubic inches piston displacement for every rated horse-power in the average American motor, and 12½ cubic inches per horse-power in European motors.

(*b*) Mr. Clough, taking the piston displacement and rated horse-power of the horizontal motors of twenty-two American cars, finds that the average manufacturer gives 19·13 cubic inches displacement per horse-power.

(*c*) The *Motor-Car Journal* (July 25th, 1903) publishes, as average, taken from twenty-two motors, a displacement of 173 litres (10,481·2 cubic inches) per minute per horse-power.

(*d*) Mr. C. W. S. Crawley, in a paper, "The Limitation of Cylinder Capacity," read before the Automobile Club, November 12th, 1903, states

The above illustration, which is reproduced from a Photograph sent us by Turner's Motor Manufacturing Co., depicts one of their Turner-Miesse Steam Cars and a De Dion Petrol Vehicle, at Penang, in the Malay Peninsula.

that an average taken from all the cars entered in the 1903 Reliability Trials was 10 cubic inches per horse-power.

(*e*) The writer, dealing with the same motors, but classifying them according to the number of cylinders, found that there is, on the whole, a gradual increase in the piston displacement required, as cylinders are multiplied. Taking the total displacements of the one, two, three, four, and six-cylinder motor entered, and dividing by their respective total rated horse-power, the results were as follows :—

Number of cylinders.	Mean displacement per B.H.P., cubic inches.
One-cylinder motors	8·65
Two-cylinder motors	12·08
Three-cylinder motors	11·25
Four-cylinder motors	12·75
Six-cylinder motors	13·80

Summarising the horse-power calculated by piston displacements, we have :—

Motor.	Maker's rating.	Calculated from piston displacement by			
		Duryea.	*Motor Car Journal.*	Crawley.	Longridge.
	H.P.				
2-cylinder Wolseley ...	7½	8·02	7·16	10·04	8·30
3-cylinder Maudslay ...	25	23·55	22·47	29·43	22·16
4-cylinder Star	18	18·08	17·24	22·60	17·72

These figures are, perhaps, slightly more satisfactory than those obtained from such horse-power formulæ as omit the mean pressure; but they are clearly of little practical value. The reason is obvious. Different motors, even of the same bore and stroke, vary in compression, cooling surfaces, valve resistance, suction temperature, quality of the mixture, correctness of timing, silencer, back pressure, workmanship, &c., &c.—more than all, in speed, a factor vitally affecting the displacement per horse-power. Assuming equally favourable conditions of design, the value of the cubic inch displacement in the high-speed motor will evidently be proportionately greater than in the low-speed engine; and, if accurate computation is to be made on piston displacement, it must, for one thing, be based on averages taken from motors of equal speed.

From a comparison of rather over 100 British motors, classified according to the number of revolutions per minute, the average piston displacement per B.H.P. is :—

With motors of 750-800 revs. per min. ...	12·5 cubic inches.
„ „ 900-1000 „ „ ...	11·0 „ „
„ „ 1100-1200 „ „ ...	9·4 „ „
„ „ 1400-1600 „ „ ...	6·7 „ „

Using such averages as constants, an empirical horse-power formula of simple form could be constructed :—

$$H.P. = \frac{A \times S}{C} \times N,$$

Where A = piston area in square inches,
S = piston stroke in inches,
C = the average piston displacement for a motor of the given number of revolutions per minute,
N = number of cylinders.

Applied to the motors already mentioned, the formula gives :—

Rated by maker.	Computed by formula.
7½-h.p. Wolseley	8·36 h.p.
25 „ Maudslay	23·55 „
18 „ Star	18·08 „
22 „ Daimler	21·60 „

Even here the results do not very closely agree with the makers' ratings; but possibly nearer agreement could be obtained if the constants were averaged from a larger number of motors. It should be noted that the above average piston displacements do not apply to French motors, as sold in England. Either such motors require larger displacements per horse-power, or the rating at which they are sold is considerably under their real power.

If more data as to mean pressure were available, and if less variations in design prevailed, a useful chart could be readily constructed by which the horse-power could be computed. In the meantime, it would be more satisfactory to the public, and more beneficial to the trade, if makers gave not only the accurate rating, but the number of revolutions at which that horse-power was developed, and also the fuel consumption. —*The Engineer.*

APPEALS BY MOTORISTS.

At Norfolk Quarter Sessions, the appeal of Henry Palmer Collis, appellant, and Edward Gilbert and William James Owen Holmes, two of the justices of the peace for the Petty Sessional Division of Blofield and Walsham, in the county of Norfolk, respondents, has been heard. Mr. Kemp, K.C., with Mr. Eversley, for the appellant; and Mr. Low, K.C., with Mr. Wild, for the respondents. The appeal was against a conviction by the said justices on the 4th day of July, 1904, for that he, the said Henry Palmer Collis, did on the 12th day of June, 1904, unlawfully drive a certain motor-car recklessly on a certain public highway, to wit, the highway leading from Blofield to Witton, in the said county of Norfolk, contrary to the Statute in such case made and provided, and the said Henry Palmer Collis was fined £5 and costs. The Bench, after a brief deliberation, dismissed the appeal with costs.

Another case was heard at the Norfolk Quarter Sessions in which Albert Higgs was the appellant, and Edward Denham Spurrell and Francis Hubert Barclay, two of the justices of the peace for the Petty Sessional Division of North Erpingham, respondents. This was an appeal against a conviction by the said justices on the 12th day of September, 1904, for that he the said Albert Higgs did on the 21st day of August, 1904, unlawfully drive a certain motor car recklessly on a certain public highway in the parish of Sheringham, in the county of Norfolk, contrary to the Statute in such case made and provided, and the said Albert Higgs was fined £10 and costs, and his licence was ordered to be endorsed. Mr. Horace Avory, K.C., with Mr. E. E. Wild, for the appellant; and Mr. Freeman Barrett, with Mr. Carlos Lumsden, for the respondents. The Court allowed the appeal, and quashed the conviction, without costs. The Chairman added that he had very little doubt if the magistrates in the court below had had the additional evidence before them they would have seen their way to come to a different conclusion. On the application of Mr. Avory the endorsement on the appellant's licence was ordered to be cancelled.

Mr. Alfred Lane Joynt, solicitor, appealed at the Dublin City Sessions against a fine of £10, imposed by the magistrate on a charge preferred against the appellant of having driven his motor-car recklessly and to the danger of the public on the 7th of September in St. Stephen's Green in the middle of the day. Mr. O'Shaughnessy, K.C. (instructed

Digitized by Google

by the appellant), appeared for Mr. Joynt. After hearing counsel and witnesses, the Recorder said he would reverse the decision of the magistrate in that case. If the prosecution was brought under the 9th Section of going beyond the statutory speed, as at present advised, he would not have altered the decision. The police neglected to serve the notice sequired under the section.

AT the Dublin City Sessions, before Sir F. Falkiner, Recorder, Mr. Arthur H. Hardy, of Clonskeagh, appealed against the decision of Mr. Drury, who imposed a penalty of £10 for alleged reckless driving of a motor-car. Messrs. O'Shaughnessy, K.C., and Jefferson (instructed by Mr. Lane Joynt) appeared for the appellant. The Recorder said he did not see that the defendant did anything to aggravate the case on the occasion. He reduced the fine to 1s., striking out from the conviction the endorsement of Mr. Hardy's licence as a motor-driver, also the word "reckless," which was in the original conviction, the conviction to stand for driving at a speed which might be dangerous to the public.

A CASE has been heard at the Oxford Sessions in which James Tindall appealed against a conviction by the justices of the Banbury and Bloxham Division, the respondent being Supt. Smith (informant). Mr. A. H. Spokes, with Mr. Cecil Walsh, represented appellant, and Mr. A. Moresby White and Mr. Ames were for the respondents. Sir E. Bradford stated that on August 13th he had crossed the bridge from Adderbury, and was about to ascend the incline. He heard a noise of a motor coming, and Lady Bradford rode on to the path and witness went to the edge of the road in the gutter. He had ridden the horse for eighteen months, and had repeatedly passed motor-cars in safety before. The car came down the hill round the curve very fast; his horse shied, and turned towards the centre of the road. The motor struck him; he fell off, and was dragged by the stirrup some short distance. After witnesses had been heard, Mr. Moresby White addressed the justice on the rights of motor-car drivers, and after a brief deliberation in private the chairman said before giving the decision of the justice he must say one word as to the tone in which this case had been conducted by the learned counsel for the defence, and he hoped he would not repeat it there or elsewhere. They had no doubt the case satisfied the conditions under which a motor-car driver should be convicted, and the appeal would be dismissed with costs. Mr. White observed that if he had said anything offensive to the chairman or Lord Jersey he had to apologise. Now the court had come to a decision they would permit him to say, if he had imported any heat in this matter, that, though not in that court, he had in many other courts experienced gross injustice.

AN appeal under the Motor-car Act was heard by the Huntingdonshire Quarter Sessions last week. The appellant was Earl Fitzwilliam's chauffeur, who was fined £5 for driving over twenty miles an hour on the North Road. Mr. Avory, K.C., appeared for the appellant, and Mr. Raikes for the respondents. Earl Fitzwilliam, who was riding in the car, denied that it was going at the speed alleged, and declared that within the measured distance the car was stopped, as a cylinder terminal was loose, and on restarting he himself changed to another seat and let the chauffeur drive. Three constables and another witness swore that a man in a dark suit (the chauffeur) drove all the way, and that Lord Fitzwilliam, who was in a light-coloured coat, did not change places, and also that the car did not stop. The appeal was dismissed, the court believing that Earl Fitzwilliam was mistaken as to the place where the car was stopped.

CASES AGAINST MOTORISTS.

P'ace.	Summoned for	Fine.
Cardiff	Reckless driving	Dismissed.
Aberdare.....	Reckless driving	£5, etc.
Warrington	Driving negligently	£2, etc.
Pendleton	Reckless driving	£3.
Lewes	(1) no rear light; (2) not producing licence	(1) 40s.; (2) 10s.
Otley	No rear light	£5.
Wrexham	Driving recklessly	£3, etc.
Longford.....	Startling a horse by a motor-cycle	£2.
West London..... ..	Beyond legal limit	Dismissed.
,, ,, ...	Not keeping record of name of driver of manufacturer's car	To pay costs.
Brighton	Dangerous driving	40s., etc.
Lambeth	Using an unregistered motor-cycle.	Dismissed.
,,	Failing to keep a record of the use of a general identification mark	40s., etc.
Oxford	Driving furiously	Dismissed.
Lewes	Failing to produce licence	£3.
Guildford	Dangerous driving	£1.
Penge	Driving unlicensed motor-cycle	20s., etc.
Andover	Dangerous speed	£5, etc.
Folkestone	Furious driving	£2, etc.
Huddersfield	Driving dangerously	40s., etc.
Rugeley	Driving dangerously	£5, etc.
York.....	Over legal limit	Adjourned.

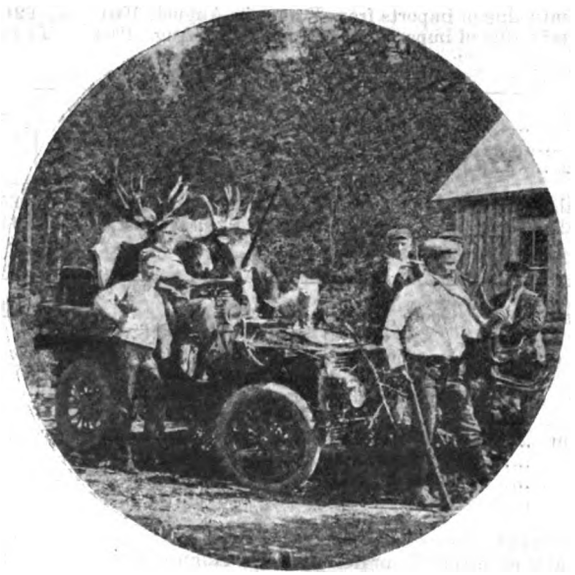
SPEED LIMIT INQUIRY AT NEWPORT, MON.

AT Newport, Mon., on Thursday of last week, Mr. E. P. Burd, an inspector of the Local Government Board, held an inquiry into an application of the Town Council for the imposition of a 10-mile speed limit over certain roads within their jurisdiction.

The Town Council was represented by Mr. F. E. Abbot, who said that the situation of Newport geographically was almost unique. For over two miles the one long street was practically the only main thoroughfare, and had to be used by the whole of the through traffic in addition to the local traffic. It was the most congested part of the town, and there was a continuous tram service through it. The Council believed that the granting of the proposed regulations would give greater security to the public, and would ensure greater care in the management of cars using these roads.

Mr. Haynes, the Borough Engineer, said that the passing of the regulations would necessitate the erection of eighteen warning-boards at a cost of £4 each for erection, and of 3s. 6d. to 4s. each per annum for maintenance. If they were illuminated at night they would cost about £3 each per annum.

Mr. Rees Jeffreys, addressing the inspector, said the opponents were placed in an extraordinary position by the neglect of the Town Council to call evidence in support of their application, and by the virtual collapse of their case.



The Hon. J. M. Rolls, D.L., J.P., who is a member of the County Council of Monmouthshire, said he appeared on behalf of the Automobile Club to oppose the application. He thought the existing powers were quite sufficient for the regulation of motor traffic, and that the proposed new regulations would not secure the safety of the public. He was familiar with the streets upon which the Town Council wished to impose a 10-mile limit. He did not consider that the streets of Newport presented any special difficulties.

Mr. J. J. Neale, Cardiff, manager of the Cardiff Ice and Cold Storage Company, said he appeared on behalf of the South Wales and Monmouthshire A.C. These regulations, if passed, would be detrimental and vexatious to the members of that club, who, in large numbers, passed through Newport on their way to the Wye Valley or to the North. He objected to the limiting of the speed of motor-cars to 10 miles an hour.

Mr. R. J. Brind, official handicapper and timekeeper of the South Wales and Monmouthshire Automobile Club, said that, in conjunction with Mr. H. J. Powell, he had on October 12th taken the times of a number of trams over a distance of 110 yards in Commercial Street, and also in Clarence Place. The times and figures show that eleven cars went over 10 and up to 11 miles an hour, eight cars went at over 11 and up to 12 miles an hour, eleven at over 12 and up to 13 miles an hour, and fourteen at over 13 and up to 15 miles an hour. On another occasion he had timed the trams and found that fourteen cars went at over 12 and up to 14 miles an hour, and that six went at over 14 and up to 17 miles an hour, while two cars went at over 17 miles an hour.

Mr. E. M. Linton, Newport, and Mr. H. J. Powell, Cardiff, assistant secretary to the South Wales and Monmouthshire A.C. and hon. secretary of the South Wales Centre N.C.U., objected to the proposed restrictions. Messrs. H. A. Jones and J. Matthews, of Newport, also stated that the proposed regulations would not be in the interests of the public safety.

Mr. A. Arthur Dale, a member of the general committee of the Motor Union and hon. secretary of the Gloucestershire A.C., said that for the avoidance of accidents it was necessary to give a free hand to drivers to increase their speed when passing tramcars and other vehicles. The great controllability of motor vehicles rendered a limit unnecessary.

CLUBS AND ASSOCIATIONS.

NOTTINGHAM.

THE dinner in celebration of the opening of the winter session of the Nottinghamshire Automobile Club was held last week at the Black Boy Hotel, Nottingham, the president (Mr. C. Hardy) being in the chair. After the loyal toasts had been honoured prizes were presented to the winners of club events and to the toast of "Automobilism" reply was made by Mr. S. F. Edge, who said the four drivers of Napier cars taking part in the eliminating trials of next year were to have three or four months' actual training for the event. He advocated a training school for chauffeurs, and said that professional drivers should be obliged to pass examinations and be under very stringent regulations. Every accident, too, ought to be carefully investigated. Mr. E. W. Wells proposed the health of "The prize-winners." Messrs. Ross Browne, Ernison, Bennett, Wright and Edge briefly responded. The secretary (Mr. A. R. Atkey), proposed the toast of "Mr. W. F. Foster," and that gentleman responded. During the course of the evening Mr. J. C. Wilson, a newly-elected member of the club, promised to give a trophy for another long-distance run next season.

NORTHAMPTONSHIRE.

THE Northamptonshire Automobile Club are making special arrangements for their winter session. The committee announce their intention to interest the members by a series of lectures on "Motoring in General," as well as by a succession of smoking concerts.

MOTORS AND TOLL-GATES.

BEFORE Judge Gye, at Southampton, last week, Mr. John Kemp-Welch, J.P., of Christchurch, sued Mr. James Hotspur, of Ealing, for damages to his motor-car, caused through the negligence of the defendant or his servants. It was alleged that while Mr. Kemp-Welch was motoring along the Botley road, the tolls over which had been paid, the toll-gate keeper suddenly rushed out of a cottage and closed the bar, into which the car crashed. The vehicle at the time was travelling at the rate of sixteen miles an hour and sustained damages. Defendant leased the tolls from the company over whose road the plaintiff's car passed. The defence was that it was the keeper's duty to collect tolls, and as the toll-bars were repeatedly "rushed" by motorists they were compelled to close the bar in duty to their employers. His Honour gave judgment for the defendant, with costs.

A KENTISH CASE.

AT the Maidstone Quarter Sessions, Lieut., H. C. Davies, of the Welsh Regiment, appealed against a conviction of the justices of Tonbridge, Kent, whereby he was convicted for that he did on the 28th day of August, 1904, on a public highway, to wit, the London Road, Southborough, Kent, unlawfully drive his motor-car in a manner which was dangerous to the public, having regard to the circumstances of the case, and he was fined the sum of 40s., and ordered to pay the costs, and his licence was endorsed. Mr. A. Moresby White and Mr. A. W. Gans, instructed by Mr. S. Firth, appeared for the appellant, who deposed that he was driving his car from Eastbourne to Gravesend; that he was coming through Southborough, and that his speed was not more than ten to twelve miles an hour; that he was keeping a good look out, and that, so far from going fast, one of his back tyres had burst. Moreover, he stated that he did not notice anybody in the road, and that he certainly did not inconvenience anyone. His brother gave evidence that he was the previous owner of the car in question, and spoke as to its capabilities. In the result the conviction was quashed, and the appeal was allowed.

TO CORRESPONDENTS.

All communications intended for insertion in this Journal or relating to Editorial matters should be addressed to THE EDITORIAL DEPARTMENT, MOTOR-CAR JOURNAL, *39 and 40, Shoe Lane, London, E.C., and must be written on one side of the paper only. Letters must in all cases be accompanied by the name and address of the writer, as no notice will be taken of anonymous communications.*

The Editors cannot undertake to return MSS. or drawings, although every effort will be made to do so in the case of rejected communications. Where such are regarded as of value, correspondents are requested to retain copies.

COMMENTS.

ALMOST before the recent trials at Blackpool had come to a close a second meet at an early date was talked about. Those who took part in the trials at the middle of last month were so favourably impressed by the track, that the possibility of the world's record for the flying kilometre being broken on it was seriously discussed. The consent of the Town Council for the promenade to be used for the purpose of making an attempt on the record having been readily accorded, the event, originally intended for Saturday next, will now probably take place on the 19th. The permit of the Automobile Club has been obtained, and this, along with the attendance of the Club's official timekeepers, will ensure the international acceptance of the times recorded. One result of a visit to London of a deputation from the local committee has been to confirm the opinion that the last meeting at Blackpool was one of the best ever held, and there is every prospect of this success being repeated.

◆ ◆ ◆

Classes and Competitors.

THE chief feature of the trials, should they, as the local people hope, take place, will be the class for large racing cars up to 1,000 kilos. An entrance fee will be charged for each vehicle, and in the case of the 1,000 kilos class it is probable that a substantial purse may be given to the competitor lowering the world's record, the prize going to the car establishing the best time in the event of more than one achieving this feat. Medals will probably be given in the other classes. There will also be classes for motor-cycles. A departure from the procedure at the last meeting will be that, instead of the races being run against the watch, the timing will be done by electricity. The meeting should be a thoroughly representative one, the presence of many of the world's leading racers having been promised. Mr. S. F. Edge has consented to compete with his six-cylinder Napier racer which did so well at Gaillon on Sunday last. Mr. A. Rawlinson has intimated his intention of being present with his British Darracq; Mr. Andrew Fletcher, who was one of the first to suggest the meet, will be there with his 90-h.p. Mercedes; Mr. Clifford Earp with the 100-h.p. Napier; and the Hon. C. S. Rolls with his 100-h.p. Mors, of which better things are expected than at the previous trials. Invitations have been issued to prominent Continental racing men, and it is fully expected that the Gobron-Brillié car on which Rigolly established the world's record will be brought over, and probably the Hotchkiss, with Le Blon as driver; Baras may also be amongst the competitors on a Darracq car.

◆ ◆ ◆

The Track.

MUCH discussion has taken place as to the suitability of the track for record-breaking purposes, owing to a very slight curve, which, it has been argued, presents a danger when a speed of 100 miles an hour is attained. Experts who have had experience of the course have, however, declared that this slight bend offers no obstacle, and that, with a car running alone, a bee line from end to end can be obtained. The opinion has also been expressed that if records are to be obtained in England, they are obtainable at Blackpool, where the surface of the course is very fast. The success of the event seems assured, and vast numbers of people will no doubt pour into the popular Lancashire seaside resort. For, while it is no secret that on the first day of the last trials the proceedings were voted a "bit tame," owing largely to the long intervals between the despatch of the cars, a high pitch of enthusiasm was reached on the afternoon of the second day, which was chiefly devoted to the large racing cars. As to the probability of the record being broken, a great deal of course depends upon the conditions prevailing at the time, but should these be favourable, there is, it is considered, a reasonable prospect of Rigolly's time being beaten. Should this prove to be the case, the meet will have more than justified itself, and Blackpool will have added another to its long list of ambitions which have been realised.

◆ ◆ ◆

On Prohibited Roads.

THERE are local terrors in store for motorists in strange places, as a Glasgow lawyer who went a-motoring on the Trossachs road, Dunblane, has just discovered. He travelled very carefully without annoying anybody, or frightening even the smallest animal. But the road has been scheduled by the Secretary of State for Scotland as closed to motor traffic. And consequently the lawyer was summoned to the police court to receive a lecture from a Sheriff-Substitute, and to leave the sum of three guineas with the local police. When roads are prohibited notices should be prominent and frequent along the whole of the distance, so that those who drive may read.

◆ ◆ ◆

Motors and the Law.

THE useful summary of the legislation with regard to automobiles which Mr. Montague Barlow has given the members of the Solicitors' Managing Clerks' Association, and which is reprinted on another page, will doubtless be read with interest by the many victims of the Act. These have become a fairly numerous body, although hardly enough to warrant the formation, as a correspondent suggests, of a Motor-Car Victims' Protection Association. This ought to be the work of the Motor Union and the various local clubs which are now in existence throughout the country. They, too, can render useful work in reminding their members that the operation of the present Act will cease at the end of another two years, when the whole question will be reviewed again by the Legislature. Hence the necessity for care on the part of individual motorists.

◆ ◆ ◆

The Mutual Protection Association.

THE recent meeting of the Automobile Mutual Protection Association had a special interest, and the proceedings last week, briefly chronicled on another page, indicate considerable enterprise of a kind likely to be of value to the industry. The British people are a practical race,

Digitized by Google

and rightly pay heed to the experience of other nations before adopting new methods or lending countenance to ideas that have only the enthusiasm of advocates to recommend. Hence the tour of investigation upon which the secretary has set out should result in the collection of information calculated to assist the progress of the heavy motor movement. Here, as in the case of light cars, much depends upon road problems, the elucidation of which will be materially assisted by knowledge of continental experience.

◆ ◆ ◆

The Dust Problem in London.

THE Borough Engineer of Kensington has been experimenting with dust-laying oils — pyneoiline, and Westrumite — in road-watering, and in a detailed report on the subject expresses the opinion that these dust-layers are unsuitable for use in London, and the adoption of either in Kensington at the present prices for the oils would at least double the cost of the work of road-watering. The smell would also give cause for much complaint. The Borough Council of that western borough does not, therefore, intend to proceed with the trials. So far as the Metropolis is concerned, the matter will have to be considered with regard to London as a whole, and not merely as a local question.

◆ ◆ ◆

The Kaiser at the German Military Manœuvres.

◆ ◆

A Trial of Headlights.

MONTHS ago the suggestion in these columns for a trial of headlights produced some correspondence from makers who expressed themselves as anxious to assist in the effort to secure a satisfactory light for automobiles. There the matter has rested, until the frequency of mishaps owing to the inefficient lighting of other vehicles has again insisted on public attention being riveted on the subject. Captain Deasy, too, has revived the proposal for a trial of headlights, and whether this takes place or not we trust the subject will have full discussion. In our correspondence columns a gentleman who has studied the question gives some useful opinions, and while we would not identify ourselves with all he says, the letter should serve the purpose of inaugurating a discussion of particular interest to all concerned with lamps and lights. The glare of the headlight has its drawbacks, undoubtedly, and these can, and must be, minimised. Probably some who have had manufacturing experience will give their views as to the lines upon which any really adequate trial should be conducted. If this is attempted it should be organised without delay, so that the advantage of dark nights and long evenings can be available for the judges.

The End of the Run.

IT was a foggy morning when the two Oldsmobiles which Messrs. Jarrott and Letts, Limited, sent on a 3,000 miles' pilgrimage for thirty days returned to town on Thursday of last week. They were welcomed at Barnet by a number of well-known motorists, and came into Great Marlborough Street, London, at the end of a goodly calvacade of cars of higher power. A great crowd had collected, and although buyers were probably absent, enthusiasm was not lacking. Messrs. Bell and Batchelor, the drivers, who had made their daily round with unfailing regularity, piloted their cars into the showrooms, where Mr. W. M. Letts voiced the pleasure of the firm at their achievement and handed each a silver cup as a memento of their long and arduous ride. During the week the vehicles have been on view to the public, the condition of the engines and gears being such that Messrs. Jarrott and Letts would have no hesitation in sending them on a further 3,000 miles' journey.

◆ ◆ ◆

Some Experiences.

THE cars went practically over every portion of England, Scotland and Wales, and 400 miles of wretched roads in Ireland. They encountered every kind of weather, and at times the drivers were almost ready to give up at the end of the day's journey, after travelling for hours through a dense fog or pouring rain, with roads absolutely indescribable. The drivers carried a book which has been signed by each hotel proprietor where they have lunched, and also where they have slept at night, thus proving conclusively that they were in the towns arranged for them at the commencement of the tour, although it was very hard at times to keep up to the programme, chiefly owing to fog. The only accident which might have proved serious was on the road to Bath, when travelling over roads made slippery by two days of rain and fog, the large car had a side-slip and went into a ditch, and a team of horses and chains had to be requisitioned to pull the car out. This somewhat strained the vehicle and broke two of the bolts of the spring and shifted the engine a little, but after some assistance at Bath they were able to continue the run. The little car on the same day had a side-slip which ended against a brick wall, bending the front axle; this was straightened, and they were both able to continue the journey. With these exceptions they had no troubles whatever beyond just a few simple adjustments. They have also been wonderfully fortunate with their tyres, having comparatively few punctures.

◆ ◆ ◆

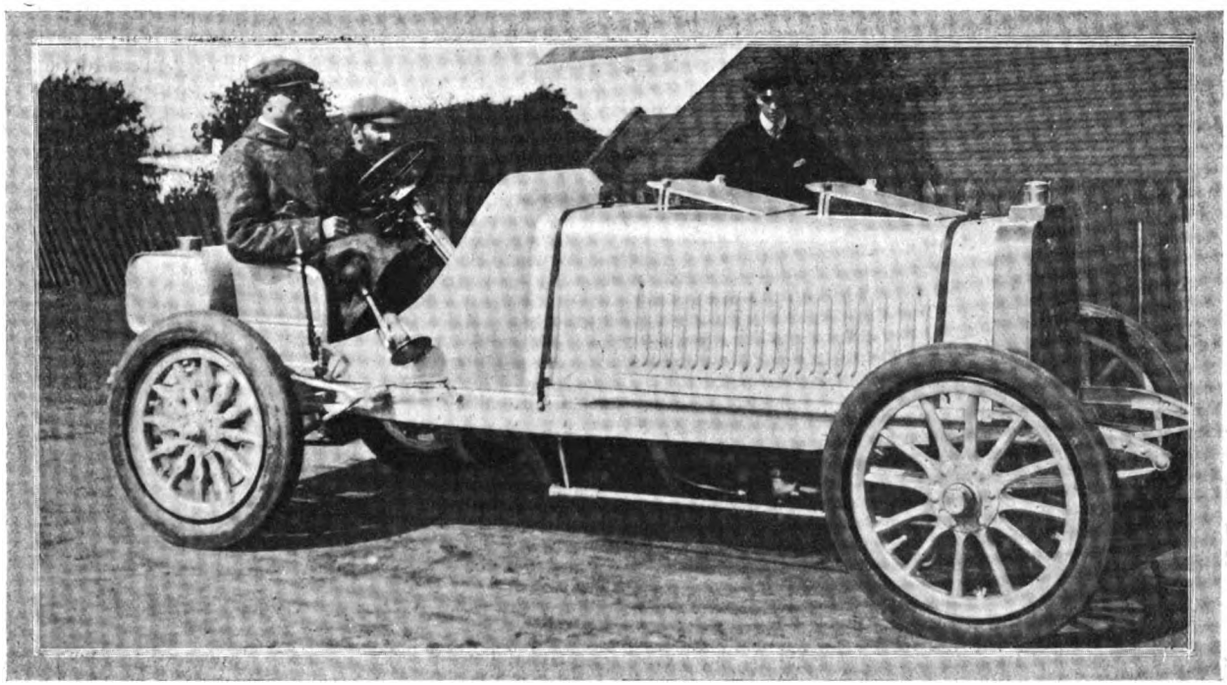
From Dover to Putney.

LAST week we referred to the venturesome voyage of Mr. A. L. Guinness from Dover to Putney on his newly-acquired Mercedes IV. There were few sailors at the Kentish port who would accompany him on the novel trip and many were the refusals to set foot in the strange little craft. At length, with the kindly services of the Deputy Harbour Master, Mr. Guinness found a willing seaman, and this volunteer with the owner and his man formed the crew of three who started about nine o'clock one morning. Just off the Admiralty Pier rough seas were encountered and for a few minutes the enthusiasm of the voyagers was damped and subdued. But their pilot assured the two other members of the crew that they would soon be in smoother water and all went well until Ramsgate was reached. There the waves rose high and Mr. Guinness had to be continually drawing the clutch to dodge the seas. Rounding the North Foreland was a strange experience; the wind was south-west and a north-easterly swell met the tide. Mercedes IV. wisely kept inside the Long Nose Buoy.

◆ ◆ ◆

Up the River.

THE North Foreland being safely passed the boat was run at full speed for the first time. Margate was quickly reached, and, landing there to fill the petrol tanks, the voyagers learned that their craft had been mistaken for a whale when they were out at sea. After a stay of about three-quarters



Digitized by Google

of an hour a re-start was made, and the land was kept in sight until just off Sheerness a fog was entered. The compass was useless, for it was found to be making almost as many revolutions as the engine. The course had to be steered by the barges that were passed until the Thames received the boat into her waters. A comparatively uneventful trip was then made to Putney, which was reached at four o'clock in the afternoon. The motor ran well all the time, and from Margate to the destination there was no need to draw the clutch. After the boat was moored and the 90-h.p. engine had ceased its booming the air seemed full of quietness. For six hours the crew had listened to an engine without a silencer, never being able to escape from its roar and its rumble. The pluck of Mr. Guinness in undertaking such a trip was unmistakeable, and marks him out as one of our premier motor-boaters.

◆ ◆ ◆

On the Thames.

THE recent floating into popularity of motor-boats on the Thames has naturally caused the members of the Thames Conservancy to give increased attention to the possible dangers arising from their presence on the river. A committee of that body is now considering what special rules should be made for the governance of such craft on the Thames, and it is to be hoped that the representations of practical experts in motor-boating will be fully considered. Whilst we recognise that wise discretion should regulate motor-boats on a river so much given to pleasure-boating as is the Thames in its upper reaches, it would be a great pity if the viciousness which characterised some of the earlier doings with regard to motors on the road was emulated on the river. Given reliable boats and careful steersmen, there is no reason why petrol launches should not become even more familiar features on the Thames, without being an annoyance to the users of ordinary boats.

Mr. A. L. Guinness on his 100-h.p. Darracq Racer.

◆ ◆ ◆

Alcohol for Motors.

SUPPLEMENTING the report of Dr. Ormandy's lecture on another page, a Lincoln correspondent informs us that reference was made to the fact that petrol and alcohol would not satisfactorily mix, for petrol was not soluble in alcohol. When benzine was used with alcohol, the exhaust was very obnoxious. The cost of this spirit, with potatoes at a pound a ton, was a shilling a gallon, and with proper carburettors, higher compression and heating jacket (with petrol engine the heat had to be got rid of) it was very efficient. The makers of the Bel-size car were running a one-cylinder alcohol engine, and would shortly have a three-cylinder car on the road run by this spirit.

◆ ◆ ◆

Driving Certificates.

THE Committee of the Automobile Club have been considering representations made by the Royal Marine Artillery Committee of Portsmouth, asking the Club to carry out a practical and theoretical automobile examination in the spring of next year, and to issue certificates to such members of the Royal Marine Artillery Class as may deserve them. It has been pointed out that all members of this class have had previous knowledge of electricity and machinery—many are skilful artificers—and, as all are within ten months of taking their discharge, the test should provide useful men for civil employment. We hear that the Club Committee has approved of the principle of sending representatives to conduct the examination, and it may happen that the correspondence that has already taken place may prove the initiative for the organisation of a regular system of giving driving certificates which would have some authoritative weight. There is no doubt that there are a good many men up and down the country who would be glad to prepare themselves for a real examination in motor driving, and that if such a system were properly prepared and superintended it would be appreciated both by employers and employed. It must be confessed that outside the few technical institutions which are now giving attention to automobilism, the opportunities for really useful certificates are sparse indeed. While, on the other hand, several of those who profess to be in a position to offer diplomas, etc., have really no official standing, and the certificates issued are generally of no value to the recipient.

◆ ◆ ◆

Actuality in Teaching.

WRITING of instruction in motor-car work we would suggest to the teachers at the technical institutes now giving attention to the subject that no lectures should be unaccompanied with actual specimens of the motor-parts they describe. Blackboard illustrations and slides thrown upon a

Digitized by Google

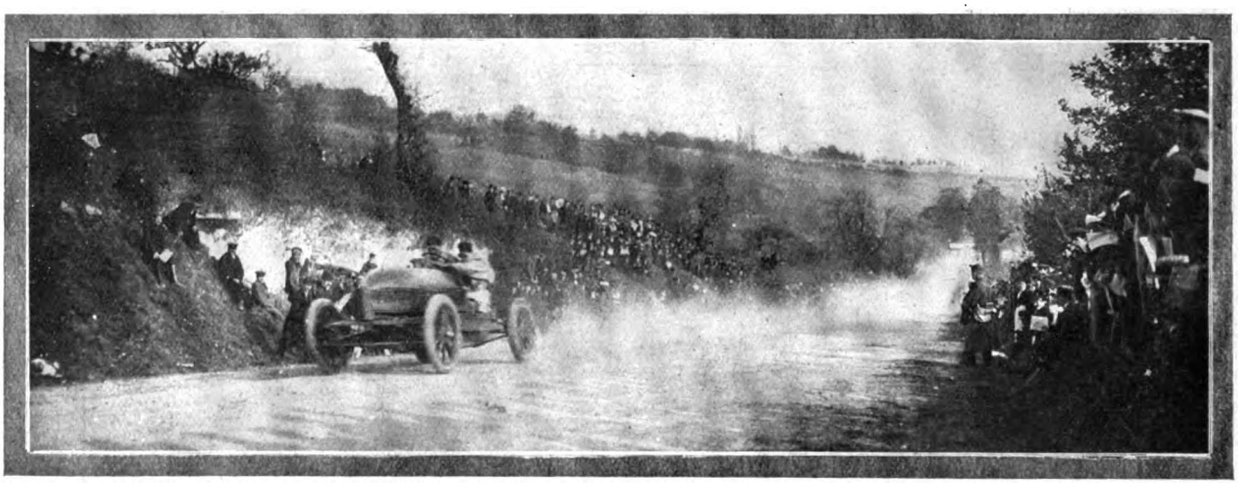
screen are useful, but they should be regarded as supplementary to the actual machines or parts, and not intended to wholly supply their place. In such classes very little should be taken for granted, and the operations of even the most elementary accessories should be described, actuality being given to the lesson by models and parts. Seeing that technical instruction in automobilism is yet in its infancy, it is desirable that the initial courses should be very carefully prepared and nothing left undone to give thoroughness to the teaching provided.

◆ ◆ ◆

Herefordshire.

AN echo of the recent small car reliability trials in Herefordshire comes in the presentation of a silver medal to Mr. Wilfred Groom, the Hon. Sec. of the local club, to whose initiative and enterprise much of the success of the event, and certainly its inception, was due. In securing the trials being held in that district, Mr. Groom did yeoman service in the education of the public in a county where county families are plentiful and motor-cars have hitherto been comparatively few. The Herefordshire Club has already rendered much useful service to the movement, and the way in which it has always kept on good terms with the police and county and other authorities proves that where automobilists are organised for social purposes as well as the advancement of the movement, troubles with the police have become fewer and less intense than in other localities, where motorists are merely isolated units without the mutual help that comes from association in a common cause.

◆ ◆ ◆



King Frost.

THERE are still, alas! a number—rapidly becoming, as far as influence goes, a minority—of blind reactionaries who refuse to see anything good in the automobile, and, impervious to argument, can only be left to the healing work of time. But if anything will convince the motophobe, a good hard frost, especially if following wet weather, will do it. At such a time the horse-owner, unable to go out without the fear of letting his horses down, can only abuse the local authorities for their feeble attempts to cope with the slippery state of the roads, and in the intervals envy the motorist, who goes on his way without a qualm. For Nature has beneficently decreed that frozen roads, however glassy, are with moderate care safe, and with good pneumatics comfortable, while his engine, if the carburettor is duly protected and warmed, never goes so well as when the outside temperature is low. Nevertheless, King Frost, who may now be expected to make his appearance at any moment, demands even from the motorist a certain special attention, not only against the risk of frozen radiators, etc.—against which sufficent warnings have been published—but in the minor but important matter of frozen lubrication. Drop-lubricators, if —as they frequently are—in a position where they are not kept warm, require special attention to ensure their functioning regularly in very cold weather, owing to the thickening of the oil. And for the same reason, the ordinary oil-can is often a tedious implement to use, and one of the varieties which has an ejector valve which forcibly drives out the oil is a time-saver at this season.

◆ ◆ ◆

Heavy Motor Vehicle Trials.

THE suggestion that a trial of heavy motor vehicles should be held on a date not too far distant has been approved of by the committee of the Automobile Club, and doubtless a programme of events will shortly be issued. Meanwhile, we are glad to see that the Club has invited the Automobile Mutual Protection Association, as well as the Industrial Committee of their own body, to express their views as to the particular form this should take. If these trials increase in number, it will soon be necessary to draw up an official programme each year, so as to avoid not only the clashing of events in which all motorists will have a kind of common interest, but also to allow of each competition taking place at a uniform interval from the others, for very often it may happen that the firms interested in one class of trials may also have vehicles entered in another. Hence, to secure the greatest success with the minimum trouble to the competitors, upon whose entries success will very much depend, some sort of definite understanding as to dates and periods during which the trials will take place should be arrived at as early as possible.

The Gaillon Hill Climb—Macdonald on the Six-Cylinder Napier.

◆ ◆ ◆

Motors and the Meet.

AGAIN the question of the presence of automobiles near the hunting field has cropped up, and we hear that novel means were adopted to take Sir John Amory's staghounds from Tiverton to the meet at Chawleigh the other day. They were placed in a van, the ends of which were wired, and drawn by a "Little Giant." The experiment proved so successful that the same means will be again adopted to take them long distances where the railway does not serve. This is a point so often urged that votaries of the motor-car are in danger of becoming wearied of it. But there are thousands of villages and larger places so distant from railway stations that the automobile is indispensable —if prompt transit is necessary.

MR. JAMES SMITH has just completed a large new motor depot facing North Street, Grantham, where not only a stock of petrol and spare parts are kept but where repairs of all kinds can be carried out. At the rear of the depot another spacious building is to be erected shortly, so that Mr. Smith will have, when his scheme is completed, a garage capable of accommodating between thirty and forty cars.

THE GAILLON HILL CLIMBING COMPETITION.

THE sixth annual hill-climbing competition at Gaillon, organised by the "Auto," was held in beautifully fine weather on Sunday last. The hill is quite straight, and the gradient averages 1 in 10, starting with one stretch of 1 in 9. It was at first intended to restrict the event to racing cars, but, probably owing to the small number of entries received, it was at the last moment decided to allow those touring vehicles which had competed in the standing mile at Chateau-Thierry on the 23rd ult. to try their luck at the Gaillon kilometre with flying start. This rapidly increased the number of entries, which, when the list had closed, had reached a total of fifty-nine, and of these forty-five were weighed in at the goods station at Vernon on Saturday last.

Gaillon is a old-fashioned little town roused into activity once a year by this event, the presence of monster racing cars in its narrow streets, lined with fifteenth century houses, forming a strange contrast. The competitors were early astir, getting their cars *au point*, and indulging in trial spins, and shortly after 9 a.m. a start was made with the touring class, the motor-cycles with engines having a cylinder capacity of a third of a litre being sent off first. There were seven competitors, and the Magali machine illustrated in the last issue of the *Journal* again attracted attention by carrying off the first three places, the time of the winner, Collomb, for the flying kilometre being 55 3-5 sec., equal to forty-one miles per hour. In the section for cars costing between £480 and £600 the best time (1 min. 27 3-5 sec.) was made by Pelser on a Serpollet steam car, Walcker on a Chenard and Walcker being second in 1 min. 33 sec. In the category for cars between £600 and £720 there were only two competitors, Cuchelet on a Peugeot doing 1 min. 17 1-5 sec., as against 1 min. 27 2-5 sec. by Robert on a Richard-Brasier. The hill-climbing capabilities of steam cars were again shown in the £720 to £1,000 class, Rulot on a Serpollet covering the kilometre in 1 min. 2 3-5 sec., as against 1 min. 4 3-5 sec. by Gasté on a Radia, a new make of petrol car which is just now attracting much attention. In the over £1,000, M. de Lareinty-Tholozan was first on a 60-h.p. Mercedes (time 49 sec.).

The turn of the racing vehicles came in the afternoon, by which time a large crowd lined the whole length of the course. The motor-cycles were again sent off first, the event proving a victory for the Peugeot machine, which secured the first two places, Lanfranchi climbing the hill in the new record time of 29 3-5 sec., an average speed of no less than seventy-six miles per hour. Cissac was second in 33 1-5 sec., and Tavenaux on an Alcyon third in 34 2-5 sec. In the voiturette section De la Touloubre on a Darracq was first in 40 sec., easily beating the only other competitor. The light car class brought out four competitors—Hanriot and A. Clement on Clement-Bayards, Hemery on a Darracq, and Coquard on a Corre. The winner proved to be Hemery, his time—32 3-5 sec.—being equal to sixty-nine miles per hour.

As at Blackpool, the display of speed by the heavy racing cars, for which the crowd had waited, was reserved to the end. Nor were they disappointed, the hill being scaled by two cars—the Darracq driven by Baras and the Gobron-Brillié handled by Rigolly—in the new record time of 29 sec., equal to just over 77½ miles an hour. The honour of the first place is thus jointly shared by the two intrepid riders. Added interest was given to the event by the appearance of the six-cylinder Napier racer, which, driven by Macdonald, gave a very good account of itself, securing third place, the time being 29 2-5 sec., or only 2-5 sec. slower than that of Baras and Rigolly. The fourth and fifth places were taken by Hotchkiss cars, Fournier's time being 32 3-5 sec. and LeBlon's 33 4-5 sec. Pelser on a Serpollet steamer was sixth in 36 1-5 sec., and Chanliaud, on a similar car, seventh in 40 1-5 sec. After the events of the day were over Baras and Rigolly were anxious to make a second attempt at the hill to decide their dead heat, but, the crowd having invaded the course, the idea had to be given up.

Gasté on the "Radia" Touring Car.

WE had a run on a six-cylinder Maudslay car developing 48-h.p. last week. No attempt was made to attain a great speed, as the car was merely out on test; notwithstanding, on short stretches of clear road the car proved very capable in this direction. The balance of the engine seemed well nigh perfect, and nothing but a humming noise could be heard when travelling, whilst vibration seemed to be reduced to a minimum.

SOME time ago the Auto Lubrine Company sent us a sample tin of the special preparation known as "Blanchine," for removing grease, oil, etc., from the hands they recently introduced. After several weeks' use we are able to report that the preparation fully answers the claims made for it as a cleanser for soiled hands, especially when used in conjunction with a nail brush. It is also efficacious as a cleanser and polisher of metals, and for removing tarnish and rust.

CONTINENTAL NOTES.

A Motor Mail Service in Sardinia.

The Italian Ministry of Public Works has approved a project for the establishment of a motor mail service between Polaro, Tempio, and Sassari, in the Island of Sardinia.

Public Service in Belgium.

A syndicate has been formed at Liege with the object of establishing a public service of motor-vehicles between that city and Maestricht. The vehicles would have seating accommodation for twenty-four persons, and would afford communication to a number of villages on the route.

The Motor Meeting at Hamburg.—The Glass of Water Race.

A Novel Trial.

The Marseilles Automobile Club proposes to hold a somewhat novel form of motor-car trial during the course of the present month. It is to be known as Average Speed Contest; each competitor, on entering, will be required to state the average speed per hour his vehicle is capable of attaining. The event is to be run off on a hilly road between Gemenos and Sainte Baume, near Marseilles, the winner being the motorist who makes the run at an average speed most nearly to that which he has specified on his entry form.

A Suggested Carriage Museum.

If the project of the well-known painter of Parisian life, M. Louis Vallet, becomes realised, France will possess another permanent museum of unique interest. M. Vallet's idea—suggested largely by the works of prophetic authors, who forecast the abandonment of horses for street work in the twenty-first century—is to organise a museum of vehicles, including in the collection those used to-day not only in Paris but in all parts of the world. Several great savants and collectors are supporting him in his scheme, and it is hoped that the State will provide a building and money for carrying the suggestion into effect. An exhibition of vehicles of the eighteenth and nineteenth centuries, which already exists at Versailles, might form the nucleus of the projected museum.

Motor-Cars as Hotel Omnibuses.

The proprietors of the Hotel des Indes, at The Hague, Holland, have set an example which might well be adopted by others, they having recently replaced their horse-drawn station 'bus by a handsomely appointed motor-car. The vehicle is a 12-h.p. two-cylinder Delahaye, and has accommodation for eight passengers, while in addition from eight to nine cwt. of luggage can be carried on the roof.

A De Dion Tour.

It has become a practice of the De Dion-Bouton Company to send one of their new cars on a long tour just prior to the Salon; the object being not only to make the new model known in various countries, but to thoroughly test the same on all classes of roads. This year it is the new 15-h.p. four-cylinder car with sliding pinion change speed gear that is to be subjected to the test, the vehicle being as usual in charge of M. Cormier. The route to be followed is, Paris, Turin, Milan, Venice, Vienna, Budapest, Belgrade, Bucharest, Warsaw, Berlin, Magdeburg, Cologne, Brussels, Luxembourg, Metz, Strasbourg, Bale and Geneva. The car left Paris on Monday.

Motor Races at Hamburg.

The North German Automobile Club held a successful meeting on the Bahrenfeld race track at Hamburg on the 23rd ult. Hieronymous on a Spitz voiturette racer won the four kilometre race for cars under 400 kilogs. in 3 min. 15 sec. The victor in the motor-bicycle class was Nicodem, who, on a Puch machine, covered 1¾ mile in 2 min. 26 sec. The 400-650 kilog. car section was a win for an Opel-Darracq driven by Hemery, whose time for four kilometres was 3 min. 13 sec. In a gymkhana which followed much amusement was caused by a race with which the driver had to be accompanied by a lady holding a glass of water, the winner being the one who spilled the least in making one lap of the track.

The 1905 Serpollet Steam Car.

It is reported that the Gardner-Serpollet Company are bringing out for the 1905 season a new type of light steam car, in which the engine will be located under the bonnet in the front of the frame, and in which in place of a condenser a radiator with fan will be employed. Improvements have also been effected in the burner by which the consumption of petrol will be greatly reduced.

The Motor Meeting at Hamburg.—Nicodem, the Winner of the Motor Cycle Section, on his Puch Machine.

A Swedish Automobile Week.

A committee has been appointed to organise an automobile week in Stockholm early next year. It is proposed that the meeting shall be held from the 4th to the 12th February next.

At a meeting of the Pontypool Urban Council a communication has been read from the Great Western Railway Company stating that they have not lost sight of the suggested motor service between Pontypool and Aberbeeg.

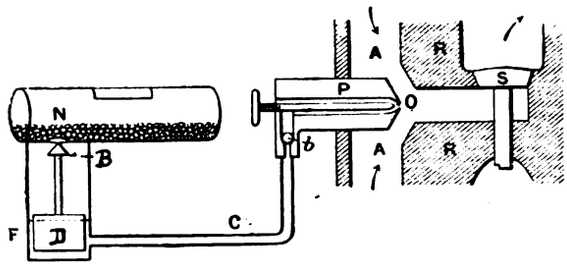
THE "DIXI" PETROL CAR.

IN a recent issue we briefly referred to a new type of petrol car which is being introduced into this country by Dixi Motors, Limited. The vehicles are being made in four sizes—6-8-h.p., 12-15-h.p., 16-20-h.p. and 24-30-h.p.—the first having two cylinder engines and the others four cylinders. We are now able to give an illustration of a 12-15-h.p. "Dixi" double phaeton, from which it will be seen at once that the vehicles are built on modern lines throughout and have a graceful, attractive appearance. The frame can either be of pressed steel or tubular construction, the latter being the one most usually fitted to the 12-15-h.p. car. Special attention has been devoted to the production of these frames, no brazing being resorted to in connecting up the various members, which are held together by special screwed sockets. A feature of the construction is the adoption of a tubular underframe on which the engine and gear box are mounted. This underframe is of U shape and is connected to cross members of the main frame at three points, one at the front, at the bottom of the "U," and at each end just behind the gear-box. The connection is by bolts passing through the underframe and the cross members, rubber buffers being introduced between them to take up vibration. To bodily remove the engine and gear-box from the frame as a unit, it is only necessary to disengage this U-shaped underframe at its three points of suspension, a matter of but a few minutes.

The motive power is supplied by a four-cylinder engine, the cylinders being 95 mm. diameter by 100 mm. stroke, and cast in two pairs. The inlet and exhaust valves are all mechanically actuated off one cam shaft and are interchangeable. The inlets are ingeniously arranged on the top of the cylinder heads. The ignition is of the usual high-tension type with trembler coil, while the water circulation is maintained by a friction-driven pump and honeycomb radiator provided with a fan. The mixture is furnished by a special type of automatic carburettor, in conjunction with which is a throttle valve controlled by the governor and also by a lever on the steering wheel. The throttle valve is of the sliding type, the spindle, however, being able to also rotate, this arrangement being adopted to allow the throttle to be actuated by hand independently of the governor.

The power is transmitted through a leather-faced aluminium cone clutch to a gear-box adapted to give three speeds and a reverse, controlled by one lever, with direct drive on the top speed. From the gear-box a cardan shaft transmits the power through bevel gearing to the rear live axle. The cardan shaft is provided with a new form of universal joint having large wearing surfaces, and protected from grease and mud. The pedals are of the push-forward type, one controlling the clutch and the other the clutch and a brake on the gear shaft; a hand lever actuates band brakes on the hubs of the rear wheels, all brakes being double-acting. The road wheels are of the artillery type and run on ball bearings. Special attention has been devoted to the question of spring suspension with the view of producing an easy riding vehicle, while the wheel base is sufficiently long to permit of the fitting of side entrance bodies. In the course of a short drive on one of the 12-15-h.p. Dixi cars through the crowded traffic in the West End we had evidence not only of the simple way in which the vehicle is controlled, but also of the flexibility of the engine, the automatic carburettor and the throttle valve enabling the car to be driven at as slow a speed as five miles an hour on the top gear.

The "Dixi" 12-15-h.p. Double Phaeton.



THE Works and Stores Committee of the Metropolitan Water Board are recommending that, as a tentative measure, licences to sell water for the use of motor-vehicles be issued to any persons supplied by meter, a charge of 10s. being made for any licence issued.

Digitized by Google

SOLID FUEL FOR INTERNAL COMBUSTION ENGINES.

AT the invitation of Messrs. J. E. Hutton, Limited, we journeyed down to their works at Thames Ditton on Thursday of last week to witness a demons tration of an internal combustion engine utilising a solid hydro-carbon naphthaline as fuel. As a matter of fact, the engine—a 12-h.p. four-cylinder Hutton—was fitted up in such a way as to utilise either petrol, ordinary paraffin, or naphthaline. The latter is a waste product of gas works, petroleum and shale oil refineries, the only use to which it has hitherto been put being to keep moths out of clothes and as a disinfectant. Two French engineers, Messrs. Chenier and Lion, have, however, for some time been experimenting with it as a motor fuel, and now claim to have perfected a method of utilising refined naphthaline in the form of white balls 5-8 in. in diameter in internal combustion engines. To the usual form of motor several additions are made, notably a special injector for vaporising either petrol or paraffin, an exhaust jacket to the inlet valves to keep the latter at a high temperature, the jacket extending right across the top of the motor, and the device, which is also heated by the exhaust, for melting and vaporising the naphthaline balls.

In the absence of detail drawings it is impossible to fully describe the system; the arrangement of the naphthaline liquifier is, however, diagrammatically shown in the accompanying illustration. The naphthaline balls are contained in the receptacle, N,

which corresponds to the usual petrol tank, except that it must be located near to the engine. An enlarged mushroom valve, B, is mounted on the top of a vertical rod which terminates in a float, D, in the chamber F. The motor has to be started with ordinary petrol until sufficient heat has been obtained to melt the balls of naphthaline into a liquid of the consistency of treacle as they fall down through the mushroom valve into the float-chamber below. The melting point of the fuel being 78 deg. Cent., it is only necessary to run on petrol for a few minutes, and when the melted naphthaline attains a certain level, the mushroom valve, B, is, of course, automatically closed, preventing a further supply of balls from falling through. During the suction stroke of the piston the liquefied naphthaline is drawn through a spraying nozzle, O, situated immediately in front of the inlet-valve, the communication between the float chamber and the jet being nominally closed by a ball-valve, *b*, which must be lifted off its seat by the suction before the liquefied naphthaline can pass to the jet. As the liquid naphthaline is sucked in, air is also drawn in through the openings A, the space under the inlet valve practically forming the mixing chamber. The degree of pulverisation can be varied by adjusting the spraying nozzle, and the amount of sprayed naphthaline fed into the cylinder can be regulated by a needle valve.

After running the engine on petrol for a short time, M. Lion, one of the inventors, switched over on to paraffin, the engine continuing to work with no perceptible variation in the running. A supply of naphthaline balls was then placed in a hopper, above the liquifier, and the engine without any cessation was changed over to the solid fuel, and continued to run as regularly as ever. It is claimed that, notwithstanding the gluey nature of the liquid, no clogging of the inlet pipe or valves takes place, but that it has, on the other hand, a cleaning action, a sparking plug, which has been in use on the engine for some time, being shown in proof of this. It is also stated that the exhaust is quite clear and not at all offensive, but unfortunately we were not able to judge of this, as, owing to an overdose of lubricating oil, the engine was not working under the best of conditions.

A series of tests have recently been made with the three different fuels—petrol, paraffin, and naphthaline balls, the results of which are shown in the appended table:—

Fuel.	H.P.	Revs. per hour.	Consumption per 12-h.p. per hour.	Cost of fuel per 12-h.p. per hour.
			lb. gal.	s. d.
Petrol	12	1,000	12·32 = 1·78	1 2½
Paraffin	12	1,000	12·1 = 1·56	0 9
Naphthaline	12	1,000	12·75	0 9

The cost has been estimated with petrol at 8d. per gallon, paraffin at 5½d. per gallon, and naphthaline at £7 per ton: the latter is, however, an outside price, and it is possible that, when bought in quantities, a much greater economy would be shown.

In acquiring the British and Colonial rights in the Chenier-Lion system of ultilising naphthaline as fuel, Messrs. Hutton have in mind its use for the engines of motor-boats and on commercial vehicles, not only because of the saving in cost as compared with petrol, but more especially on account of the greatly reduced risk of accident, naphthaline, which takes up no more space than petrol, being not nearly so inflammable as the spirit. As proof of this Mr. Hutton dropped a lighted match into the hopper containing the balls, the match simply burning itself out. The demonstration was conclusive of the possibility of using a solid hydro-carbon as fuel in internal combustion engines, and we shall watch the development of the system with considerable interest.

MAISON-TALBOT have been appointed sole agents for London of the Wilton-Cox puncture-resisting device, to the qualities of which many testimonials have lately been received from eminent motorists. The firm has just issued a new price list.

THE London and Eastern Counties Agency for the Belsize cars has been obtained by Messrs. W. Bath and Sons, of King's Lynn and Regent's Park, who were responsible for the arrangements in connection with General Booth's motor-car tour.

THE Western Motor Company, Limited, has been registered with a capital of £5,000, to adopt an agreement with the Hozier Engineering Company, and to carry on the business of sellers of motor-cars and carriages at 70, Buchanan Street, Glasgow.

MESSRS. JARROTT AND LETTS have sent us a copy of a clever picture in colours, issued by the Turcat-Mery (De Dietrich) firm, by way of celebrating the remarkable climb of Ventoux Hill by Rougier, on a Turcat-Mery car, in August last.

SIR W. B. BARTTELOT, Bart., is one of the leading members of the Sussex Motor Road Car Company, which is about to start a service of cars between Pulborough and Worthing. A motor lorry may also be put on the road for the conveyance of goods and parcels.

THE directors of the Hozier Engineering Company (Limited), we are informed, have declared a dividend at the rate of 50 per cent. per annum on the ordinary shares for the six months ending 30th September last, which, with the interim dividend at the rate of 20 per cent. per annum, paid for the previous six months, makes the total return for the year ending on these shares 35 per cent. After providing for payment of interest on debentures, etc., and the dividend on the preference shares at the rate of 6 per cent. per annum, the directors recommend that the sum of £5,870 be applied as depreciation, £3,000 placed to "reserve" account, and the balance of £2,650 carried forward.

Digitized by Google

SOME USEFUL NOTES.

NEXT to a correct knowledge of how to use a motor-vehicle is a knowledge of how not to use it, and many otherwise good drivers do not possess this latter knowledge. The result is that they abuse their vehicles unnecessarily, and do damage to the vehicles not only needlessly, but recklessly, and then sometimes complain because repair bills are high. As an example of this abuse, recently an owner of a two-seated car wished to make a trip, taking with him four ladies, and, being unable to borrow a four or six seated car for the occasion, he mounted a temporary seat on the rear end for two, crowded the other two in the main seat with himself, and the whole party proceeded on their journey merrily. The fact that the vehicle carried the load does not prove that it was the proper thing to do, for a two-seated car is certainly overloaded when four are carried, while five becomes an abuse. The feeling that there is ample power, and that the motor does not care, is largely responsible for this tendency to abuse the motor-vehicle, for very few drivers would attempt to load five passengers in a two-seated horse-drawn trap, and if they did, the trap would not stand it long. The result of such abuse is likely to be a strained spring, wheel, or axle and a breakdown at some future time, dating its beginning from this strain.

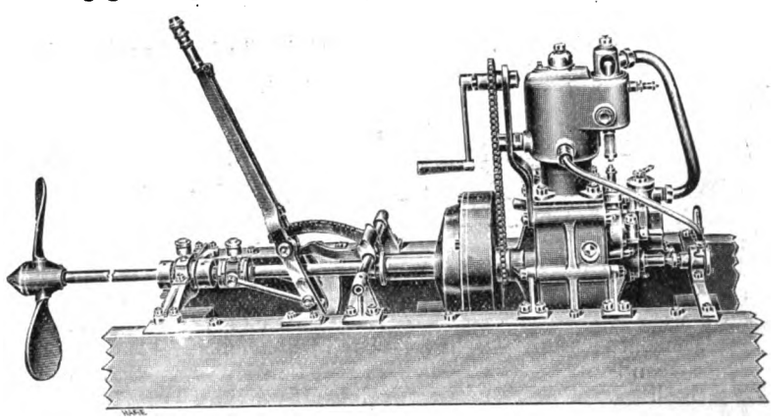
◆ ◆ ◆

A SECOND form of abuse is due to the driver's laziness. Rather than take the trouble to slow down or lift out his clutch he will bump over a newly metalled road without slackening speed, thus subjecting his car to damaging shocks needlessly. The horse-vehicle driver by years of experience has learned better and does not do this, and the experienced automobilist, having paid many repair bills, is likewise apt to do better; but the new man, "pleased with the power, speed, and staunchness of his car, is, in this strenuous age, inclined to get a lever in each hand, a pedal under each foot, the steering wheel in his teeth, and let her go, regardless of consequences. Fortunately, as we get more experienced drivers we find them discouraging this sort of foolishness.

◆ ◆ ◆

A FURTHER form of abuse is needless "racing" of the motor. The experienced driver does not, as a rule, throw the throttle wide open and let the motor try to fly out of the car while he puts on his gloves or attends to some other little errand before starting, but, on the other hand, he takes a pride in making each turn of the motor carry him as far as possible, to the saving of fuel, noise, vibration and odour, and at all times aims to keep the motor running at the lowest practical rate of speed.

◆ ◆ ◆



COUPLED with the racing motor is the sudden clutching abuse practised by the new man. With the motor running at high speed a sudden application of the clutch will cause the vehicle to jump forward or backward, as the case may be, straining all parts of the driving gear, and moving the car so quickly that persons to the front or rear are more or less in danger. Possibly such abuse is frequently due to the inexperience or ignorance of the proper way, and it seems more charitable to assume this. The experienced driver takes a pride in moving away without a jar or jerk, and this is as true in driving a motor-car as in handling a locomotive.

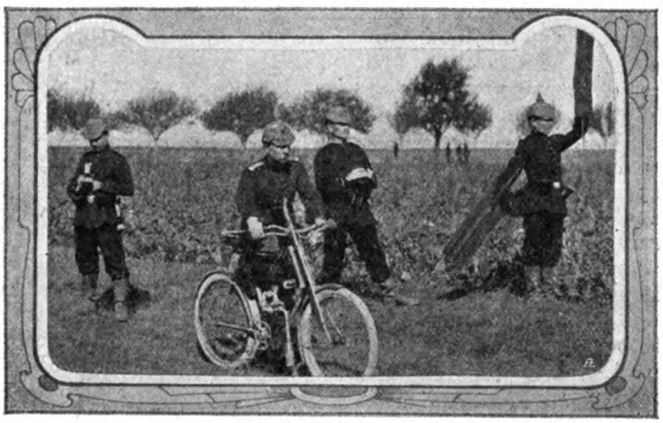
◆ ◆ ◆

A GOOD way to make a sparking plug joint, if one does not happen to have a washer at hand, is as follows:—Take a piece of copper wire, and make a ring with the ends slightly overlapping. Bevel off these ends by a tap of the hammer so that they will lie about on a level with the rest of the ring. Then heat the wire red-hot and plunge it into cold water. This will make it very soft, and should be done last of all, as manipulating the wire tends to harden it. Screw the plug down hard on this soft copper ring, and, if the job is carefully done, a first-class joint should be the result. The same method may be employed for making any joint where there is sufficient pressure to somewhat flatten the copper wire.

THE DE DION MOTOR-BOAT GEAR.

MESSRS. DE DION-BOUTON, Limited, who are devoting much attention to the motor-boat movement, have lately brought out a series of sets of combined engines with reversible propellers and control gear, ranging from 4½-h.p. single cylinder to 12-h.p. double cylinder. The accompanying illustration depicts a 6-h.p. set. The conditions under which the motor runs in a boat are somewhat different to those on cars. The engine is consequently provided with a longer shaft than usual, and on this an outside fly-wheel is mounted. This wheel is coned and fitted with a clutch to allow the propeller shaft to be disconnected from the motor. It is therefore unnecessary to stop the motor when stopping the propeller. On the motor shaft, in front of the outside fly-wheel, a chain wheel with ratchets is fitted; this is connected by a chain to a wheel fixed at the back of the cylinder. The motor is started by means of a detachable handle engaging with the boss of the top chain wheel. A rotary pump is fitted in front of the motor, to maintain the water circulation. It is driven by a jointed shaft direct from the motor axle. The pump is much smaller than those used on motor-cars, because it draws its supply from the water in which the boat floats. The special feature is the system by which one lever not only operates the clutch and inclines the propeller blades for going ahead or astern, but also allows the angle of the blades to be increased from a very fine to a coarse pitch whilst the clutch is engaged. Speed can thereby be controlled, and there is no risk

of stopping the motor by putting a full load on it at once. The power is transmitted direct to the propeller. By using a reversible propeller all pinion or other system of driving or reversing gear is dispensed with. The boss, as well as the blades, is of bronze, and the mechanism is completely enclosed. When the controlling lever is vertical the blades are set at right angles to the shaft and the clutch is disengaged. A short movement forward causes the clutch to engage and gives the blades a fine pitch for driving ahead. Further movement increases the pitch to any desired degree. Five notches in the sector provided for the purpose, with a bolt on the lever controlled by a spring and a sliding movement of the handle end, permit the handle to be fixed and the blades to be set at either of five different pitches. A movement of the lever backward along a similarly notched sector sets the blades for driving astern. The controlling lever is pivoted below the shaft. It is connected by two links to a sleeve on the shaft operating the propeller blades by a rod which slides within, and revolves with the hollow propeller shaft. This sleeve is fitted with two ball-thrust bearings. The clutch is operated by a right-angle or bell-crank lever and a roller on the controlling lever. The propeller shaft thrust bearing is fitted with two rows of balls to take up the end thrust in either direction.



A PROPOSAL is under consideration to hold a series of mile and kilometre races in the Bois de Boulogne, Paris, next month.

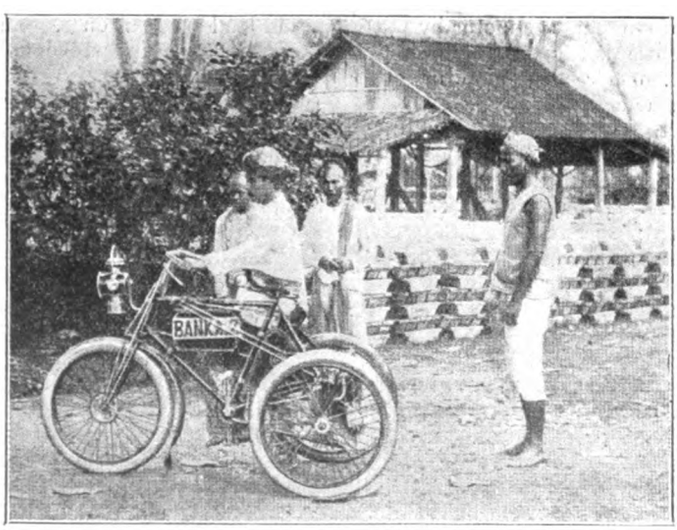
MOTOR CYCLING NEWS.

On Saturday Mr. J. Edge essayed the task of riding up the Great Orme's head, Llandudno, and was successful in piloting his 3¾-h.p. Bat to the flagstaff.

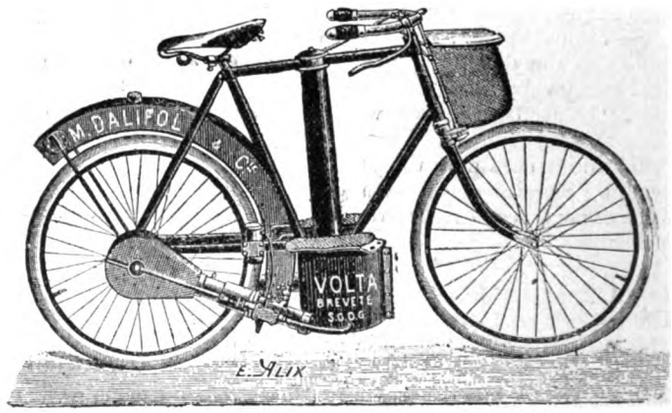


Mr. W. R. M'Taggart presided at the annual dinner of the Motor Cycle Union of Ireland in Dublin on Saturday. Mr.

A German Motor-Cycling Signalling Corps.

Lane Joynt proposed the toast of "The Union," which he said had done useful work. Mr. C. G. Grey, the hon. secretary, responded, referring in complimentary terms to the hon. treasurer, Mr. T. W. Murphy. Replying to the toast of his health, Mr. J. B. Dunlop, one of the vice-presidents, said, in his opinion, the pneumatic tyre would never be superseded in point of speed.

A new combined friction clutch and two-speed gear for motor-cycles and tri-cars is being put on the market by the E. M. Bowden's Patents Syndicate, Limited. Friction clutches are substituted for the toothed clutch, the gear being always in mesh. The wear is centred on the coned surfaces of the clutch, and replacement of the leather face—which will last several thousand miles—can be made for a few shillings. The drive is direct on the high gear, and the second gear is 50 per cent. lower, with a



Motor-Cycling in the Dutch East Indies.

free wheel between the two gears. The whole is simple, efficient, and cannot easily get out of order.

A motor-cycle record was performed on the Canning Town track on Friday of last week, when G. A. Barnes, on a Barnes motor-bicycle, beat the one hour record of 48 miles 1,395 yards, that had withstood thirty-five previous attacks, adding to his laurels by riding 49 miles 800 yards in the hour. He started beating record at 33 miles, which he covered in 39 min. 35 sec., and from that point he set up fresh figures to 50 miles, which took him 1 h. 0 min. 42 2-5 sec. After Barnes's record ride H. Martin, in an attempt on the existing figures from 61 to 100 miles, succeeded in riding his fifty-first mile in 1 h. 8 min. 39 sec., and the 100th in 2 h. 21 min. 45 sec., creating new records for every mile from 51 to 100.

Arrangements are well in hand for the Auto-Cycle Club's 100-mile trial for tri-cars, which is to be held to-day (Saturday). Every machine must be fitted with a free engine and change-speed gear. The competitors will be started at 9.30 a.m., and thereafter at one-minute intervals, from the Red Lion, Hatfield, and will be expected to accomplish the journey without any stop other than as officially ordered, except for tyres. Fifteen minutes' rest will be allowed at the half-way point, but no adjustments, etc., will be permitted. The course will be one of about 100 miles in length, and will extend over a route from Hatfield to Hertford, Newmarket, and thence to Royston, Buntingford, and Hatfield. Times may be taken on one hill, the name and position of which will be kept a secret from the competitors. On one average hill during the trials each competitor will be required to stop at a given signal as rapidly as he can by applying the brakes, without stopping his engine. As soon as the observer is satisfied that the road wheels are at rest the competitor will be

A Motor-Bicycle of 1895.

instructed to proceed. During this test the driver must not leave the saddle either for the stop or re-start. The maximum running time for the journey will be six hours, and the minimum time five hours; a competitor exceeding the speed allowed by law, whether in villages or in the open country, will render himself liable to disqualification. No petrol or oil may be taken during the journey by any competitor under pain of disqualification, though water may be taken in at Newmarket. Adjustments and repairs, the time spent on them, and their nature, will be noted by the observer. Every machine making a complete officially recorded non-stop will receive a certificate, and awards will be made on the basis of excellence in, (1) fuel consumption (2) hill climbing (3) ease of starting and control (4) brakes. These certificates may only be gained by machines arriving within the maximum time. The makers of the following machines have already signified their intention of entering:—Humber, Bat, Riley, Phœnix, Garrard, Mars, Rover, Bradbury, Quadrant, Singer, Watson, Brown, Scarsdale, King, and Lagonda.

Northern motorists are familiar with several brands of petrol which have not yet made their appearance in the South. Among these is that known as the "Giant" motor spirit, which has been introduced by Messrs. Meade-King, Robinson and Company, of Liverpool, and which has quickly earned the approval of motorists, especially those in the Lancashire district.

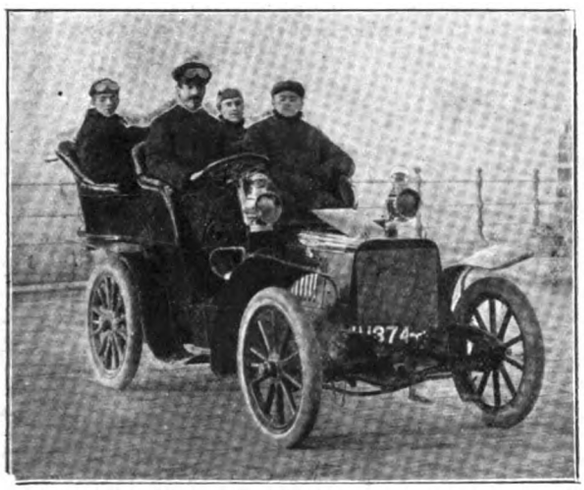
HERE AND THERE.

A MOTOR-GARAGE has been opened at Llangollen by Messrs. Moore and Company.

A LADY, Mrs. Shepherd, of Shirebrook, has just been elected to membership of the Nottinghamshire Automobile Club.

MR. H. C. DIGNASSE, of Marshall Street, W., has now the sole agency in London and the home counties for Sunbeam cars.



THE Belsize Motor Car and Engineering Company, Limited, are, we hear, busy with the construction of a new type of six-cylinder car.

THE United Motor Industries, Limited, have been appointed sole agents for the home counties for the Doherty Motor Accessories Manufacturing Company.

THE Kensington Motor Company, Limited, are removing from Hammersmith Road and Sinclair Mews, W., to their new premises in Avonmore Road, Kensington, W.

THE Hercules Motor Wagon Company are enlarging their works at Levenshulme, Manchester, and have set apart a portion of the factory for repairs to motor-cars.

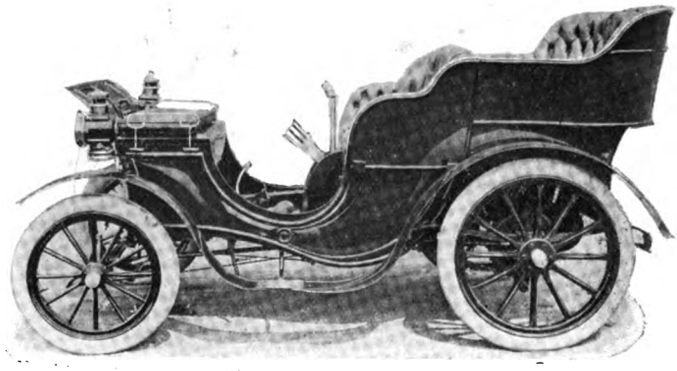
THE Prested Miners' Gas Indicating Electric Lamp Company, Limited, has just introduced a useful outfit for effectually repairing celluloid accumulator cases and other celluloid articles.

Mr. J. Keele on his 15-h.p. Darracq car at Blackpool.

THE Chairman of the Newhaven Rural District Council states that he understands 2,000 signboards, warning motorists of dangerous places, are required for the whole of East Sussex.

A SPECIAL commission of the A.C.G.B.I. has been appointed to carry out the organisation of the race for the United Kingdom cup, *i.e.*, the new cup race in which there is a limit to petrol consumption, etc.

MESSRS. J. E. HUTTON, LIMITED, have been appointed sole retail agents for Mercedes cars in 1905 for London and district. They are stocking a full set of spares and accessories for the 1902, 1903, 1904 and 1905 models.

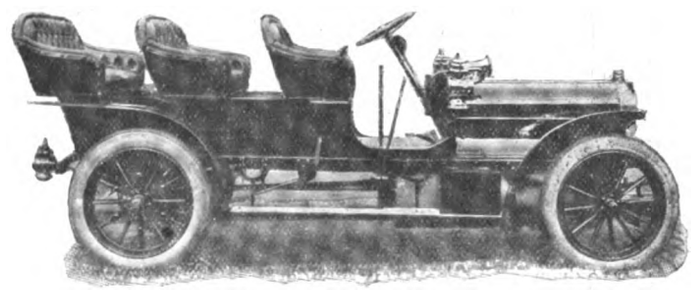


THE Highways Committee of the Cumberland County Council have withdrawn their application to the Local Government Board to issue a closing order against motor traffic on the main road from Keswick to Ambleside.

MR. W. G. CROUCHER, of Orchard Road, St. Annes-on-the-Sea, Lancashire, has fitted up a small garage, equipped with tools and machinery for the repair of motor-cars of all kinds. A large stock of petrol, tyres, spare parts, and accessories is also kept on hand.

SEVERAL automobilists were interested in the attempted sale of the Basingstoke Canal, which, with the estates in the vicinity, it had been suggested, would provide a splendid opportunity for a combination of motor boating with the pleasures of touring on land.

THE first 20-h.p. Brotherhood-Crocker car, with Mr. P. Richardson at the wheel, was seen out on the road undergoing a preliminary test a few days ago.

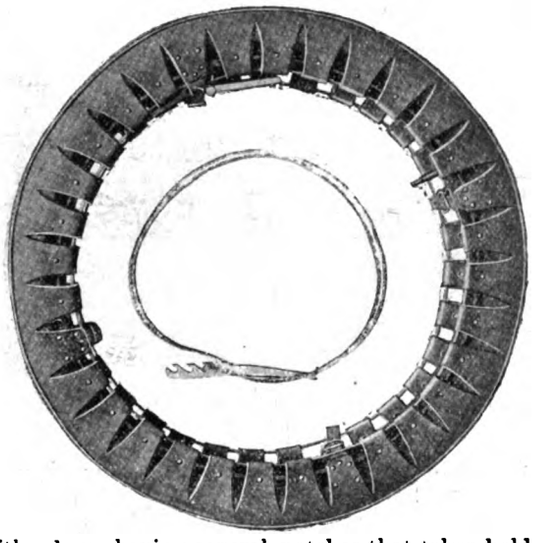


THE accompanying illustration depicts a new design of car which has recently been produced by the Duryea Company. The object is to secure a side entrance with a moderate wheel base. The front seat is made in two halves, both of which are hinged so as to swing over outwardly, thus giving access to the tonneau at the back. Either seat may be thus lifted, and only the driver

need dismount to give ingress to or egress from the tonneau. The tonneau itself is rendered exceedingly snug and compact, and, as with all Duryea cars, the rear seats are raised above the front, so that the occupants of the back seats have an uninterrupted view forwards. The particular car from which the photograph was taken was recently supplied to Mr. Mercer, of Weymouth, and, as will be seen, is also fitted with a cushion on the tool box in front, thus providing still further additional emergency accommodation if needed. This car was recently driven up to the top of the Island of Portland without difficulty, and has also made the ascent on its top gear of the well-known Ridgway Hill, between Weymouth and Dorchester.

MESSRS. T. H. S. ATKINSON, proprietors of the North of England Motor Company, Leeds, have received a second order from the Leeds Corporation for a Talbot car, for which this firm are sole agents in the Leeds district. The first car was supplied to the Tramways' Department last year, and the one now delivered to the Highways Department is a result, not only of severe test, but also of the highly satisfactory experience with the car first supplied to the Corporation. Incidentally, this is also a matter of congratulation to Messrs. Clement Talbot, Limited.

THE photograph reproduced herewith depicts a special nine-seated char-a-banc built by the Hozier Engineering Company, Limited, to the order of Mr. Leyland, of Haggerston Castle, Beal, Northumberland. The car is fitted with a four-cylinder engine of 16-20-h.p., and the special features are that the upholstery work is made so that it may be readily detached.



The rear seats can be removed, allowing the body of the car to be used for estate purposes, such as the conveying of game, luggage, guns, &c. We understand that Mr. Leyland is well satisfied with his vehicle, and is at present using it for conveying guests to his different shooting moors in the North of England, while in the winter he anticipates employing it for estate and station work.

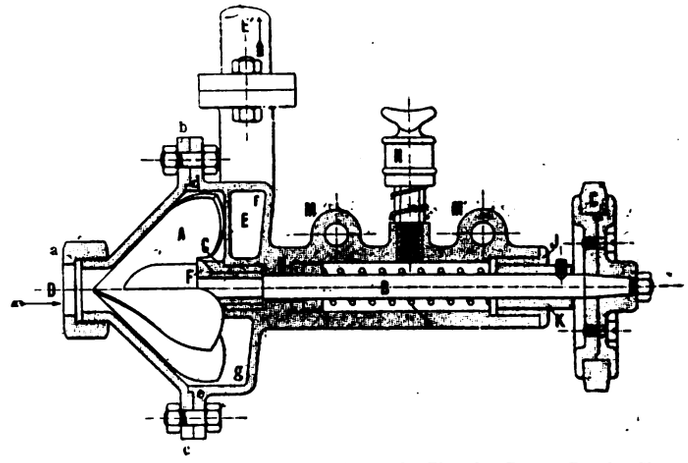
THE Holland Park Motor Company has lately supplied a special Prosper Lambert delivery van to the Central London Railway Company.

IN addition to the ordinary vulcanised non-slipping tyre tread, the Shaw Motor Tyre Tread Company, Birmingham, have just placed on the market a detachable non-slippling tyre tread cover, which can be fitted to a wheel or taken off in a few moments. It consists of a steel wire rope running through the

loops with a lever having several notches that takes hold of the other end of the rope, and when brought round regulates the tension by the various notches on the lever. It is readily adjustable and looks very neat. Side play is prevented by a clip, and we understand that there is no possibility of creeping.

A GREAT many motorists do not like to run constantly on wheels fitted with anti-skidders. An anti-skidder, say those who have had experience, is excellent for town work, but for country roads is cumbersome, and sometimes dangerous. This is an opinion that for the moment we need not discuss. We, however, call the attention of readers to what seems to be a simple anti-skidding arrangement, and one that is capable of giving satisfaction to everybody. This is the studded leather band manufactured by M. C. Beau, of Lyons, France, and which, as shown in the accompanying sketches, are secured to two con-

secutive spokes of the wheel. If the road is greasy, and a storm chances to drench the road, six bands may be taken from the box of the car and quickly laced to one of the hind wheels; and after this has been done there will, it is stated, be no danger of any skidding. The device, owing to its very simplicity, does not require any long explanation, but we may add that the maker claims that it is so perfect that when the two driving wheels of a car are provided with the bands there is an absolute freedom from skidding.



THE Seaham Harbour Works have recently supplied one of their five-ton Londonderry steam wagons to the Belfast and County Down Railway Co.

THE Finchley Road Garage, Limited, has been registered with a capital of £500 to carry on the business of motor-garage proprietors. Mr. J. G. L. Pleydell-Nott is the first director, and the office is in the Lymington Road, Hampstead, N.W.

THE Automobile Club of America has suspended Mr. H. Harkness, one of its members, for exceeding the legal speed limits of three States in a record run last June from Boston to New York. It is stated that the action was taken in fulfilment of a pledge that the club would enforce the speed limit among its members.

ONE of the features of cars of American construction is the popularity of the system of transmission by a single central chain on to a live axle. According to a recent estimate, 50 per cent. of the cars turned out in the United States are on this system, 32 per cent. are gear driven, and only 18 per cent. have side-chain transmission.

A GOOD deal of attention has lately been centred in France in the new water circulating pump brought out by the Société des Etudes Mecaniques of Levallois-Perret (Seine). A sectional view of the pump, which is known as the "Triton," is given herewith. The novelty consists in the special form of the helical screw A set on the end of the pump spindle B, rotating within the conical suction box. The four-vaned delivering screw runs just clear of the inner surfaces of the suction box, so that the

N Lubricator.

only mechanical friction existing is that in the phosphor bronze bearings at each end of the pump spindle. The makers claim that with this pump the water tank can be placed in any part of the car or at any level, and that it can circulate over seven gallons of water per minute when driven in the usual way off the motor flywheel. A spring L keeps the packing ring I in position, so that leakage of the pump is prevented. It is made in bronze or aluminium, and, in the latter metal, only weighs 4½ lbs.

THE Wandsworth Borough Council has adopted a recommendation of its Highways Committee to purchase from the Lancashire Steam Motor Company, Ltd., a steam motor wagon with a tank of 1,000 gallons' capacity for street-watering purposes, and an interchangeable wagon body, at an estimated cost of £600.

IN reply to a petition from residents in the neighbourhood of Haslemere and Farnham, asking the London and South-Western Railway Company to run a motor-omnibus service between those two places, the general manager has informed the petitioners that it is hoped that, if the roads are found suitable for such a service, it may be possible to make arrangements for its inauguration.

CORRESPONDENCE.

ECONOMICAL RUNNING.

TO THE EDITOR OF *The Motor-Car Journal.*

SIR,—I have been much interested recently in noting the fuel consumption capacities of different vehicles. The subject is one which must be viewed with increasing attention, as the use of the motor vehicle is extended and the utilitarian aspect of its various functions assumes a greater prominence. Too little attention has hitherto been given to the matter. What has been done until recently has, with the notable exception of French effort in this direction, partaken to a considerable extent of an incidental, even an accidental, nature. The small car trials in September, however, afforded much useful information on the subject, especially as the account of the fuel consumption of the different cars which was kept was a subsidiary object; the chief purpose was to get the car through the six days without a stop, and therefore only secondary importance could be attached to the fuel consumption. In the table of performances one car is a long way in advance. It was a 7-h.p. Clyde, which was driven 620 miles on a consumption of 13 gallons 1 pint of spirit. This figures out at 47·3 miles per gallon. How good this performance really is, is evidenced by a comparison with the work of the other cars in the trials. Second place was secured by a 7-h.p. Swift, with a consumption of sixteen gallons for the 620 miles, or 38·8 miles per gallon; and from this the consumption becomes greater, until the extreme point is reached with 39 gallons 7 pints, or only 15·6 miles per gallon. The work of the Clyde car demonstrates conclusively that the item of fuel expense is almost a negligible one where a light two-seated car is concerned, as in this case it figures out at less than a farthing per mile. or less than one-eighth of a penny per passenger. Another example of lower fuel consumption was afforded in the trial lately organised by the Auto-Cycle Club, when a 2¼-h.p. motor-bicycle covered a distance of 50 miles on 2½ pints of spirit, equal to 190 miles per gallon.—Yours truly,

J. C. HAYES.

TO THE EDITOR OF *The Motor-Car Journal.*

SIR,—The annexed statement of the actual cost of running my 10-h.p. Argyll car may be of interest to your readers. I have had my car for two years, and have just made up the cost for the past twelve months. My car at present is running as well as ever it did; the body and paint work have lost some of the finish, but the car does not look by any means shabby. I have used during the last twelve months 222 gallons of motor spirit, which has cost me £14 19s. 6d. As I have run 6,165 miles, this means an average of 27·77 miles per gallon. All repairs and renewals are detailed in full below:—

September, 1903	Plate fitted to frame	£0	4	0	
October, 1903	Mud guard stay	0	6	6	
December, 1903	Brake band	0	7	6	
December, 1903	Nail catchers	0	16	10	
March, 1904	Grill for horn	0	2	6	
April, 1904	Tail lamp bracket	0	9	0	
May, 1904	Two trembler blades	0	8	0	
June, 1904	Repairs time, new clutch leather and spring shackles	1	18	2	
July, 1904	Two inlet valve caps	9	1	2	
July, 1904	Repairs-time	2	5	0	
	Six piston rings	1	0	0	
	Brake parts	0	17	11	
August, 1904	Clutch coupling	0	12	6	
August, 1904	„ spring cup	0	4	6	
					9 13 7
	TYRES.				
October, 1903	Four covers retreaded	6	0	6	
June, 1904	Two new outer covers	12	3	6	
August, 1904	One inner tube repaired	0	5	0	
					18 9 0
	OILS.				
	2 gallons cylinder oil	0	10	0	
	3 „ gear box „	0	7	6	
					0 17 6
	Accumulators recharge l				0 12 6
	Petrol, 222 gallons				14 19 6
					£44 12 1

Add to this my last season's mileage and costs, and you have 9,940 miles at a cost of £56 2s. 9d., or 1·35 pence per mile, and that when generally carrying four and sometimes five persons.—Yours truly,

THOMAS P. NAISMITH.

THE USE OF THE ACCELERATOR.

TO THE EDITOR OF *The Motor-Car Journal.*

SIR,—In reply to "A. T.," the modern tendency appears to set the governors so as to cut out at a fairly high engine speed about 1,000 revolutions per minute and to drive by means of the throttle when lower speeds are required. Personally I agree with the firm's representative he speaks of. I will not go so far as to say that a car should be driven on the accelerator, as the modern tendency appears to be to decry this practice, but I must say that such a mode of control with the governors set so as to give an engine speed just sufficient to pull off with a full load, yet not to race violently when the clutch is withdrawn, appears to me far preferable to trusting to the throttle. In the first place, the control, save for the slowest crawl, on top speed is solely by the feet, leaving both hands free to steer, or one to apply the side brakes where necessary. In the second place, the speeds may be changed or the clutch withdrawn on an emergency stop without resort to the throttle to prevent the engine roaring like an angry bull, while a flick of the toe will rush one through a tight place in traffic far quicker and more easily than where the movement is by hand, and on releasing the pedal the car at once drops back to a steady twelve to fifteen miles per hour automatically. I assume the objection to driving on the accelerator is that you have with the modern four-cylinder motor and automatic carburettor so great a range of speed entirely controlled by the accelerator pedal that the inability to keep the foot quite steady puts an almost imperceptible surging action on the bevel gears, which is less marked where the control is mainly effected by the positive throttle. Be this as it may, there is to my mind a feeling of confidence where the control is carried out by the intervention of the automatic governors and the engine speed is varied by the compression and relaxation of the governor spring, whether by hand or foot, which the positive throttle independent of the governors can never give. Moreover, to one used to drive on the accelerator the want of a third hand to keep his engine cut down nicely when speed-changing without losing a revolution more than is absolutely necessary once the clutch is in again is very apparent. It would be interesting to hear what experts have to say upon the respective merits and demerits of the two systems of driving.—Yours truly,

FOOT CONTROL.

THE LIGHTING QUESTION.

TO THE EDITOR OF *The Motor-Car Journal.*

SIR,—Nothing better exemplifies the disadvantages of our hodge-podge road laws and regulations than the inconvenience and danger caused by the use of bright lights. It has recently been proposed, in the columns of a motor-car paper, that the first three lamps or so on the outskirts of a town or village should have diffusing glass on the sides facing the country, and there are other indications that the time is now ripe for drawing attention to the subject as a whole, and as including both fixed and moving lights.

Bright lights, spaced far apart, present certain difficulties, and now that incandescent mantles are so much used, street and road lamps are sometimes sources of great inconvenience and even serious danger, not only when they happen to be nearly on a level with one's eyes, and a short way off, but also when they appear over the brow of a hill and at a considerable distance.

The effect is, naturally, greatest with the outermost lamp as one approaches from the comparative darkness, but a great improvement will be made to our towns and villages when ground glass, or an equivalent, and screens are largely used and the principles of lighting properly understood and applied. Doubling the light that falls upon an object does not make it more visible if the pupil of the observer's eye be proportionately contracted.

The same optical laws hold in respect to lights on vehicles, but much more care and restraint are needed in their application. Since the whole question is one of comparative rather than absolute light effect, the best and most economical thing to do, as well as the most convenient for those who have to meet many vehicles at night, is to make use of the widely expanded pupils of the eyes and the natural light on country roads as far as possible, with such illumination of the vehicle and the road as may be necessary on dark nights or on account of shady places. To do this it is necessary to realise the twofold nature of what is now called "a light," which serves both to locate the vehicle and to light the road; or should do so.

The first necessity of traffic by night is that each vehicle show a light, and although there are physical exceptions, a bright moonlight night and on open roads, it is practically safest not to allow any departure from the rule. The principle of such a light is that of a Chinese lantern, an illuminated surface of considerable area which should be visible from almost any direction while incapable of dazzling anyone approaching or passing. There should be one at each side of the vehicle; and they should be coloured one red and one green, like a ship's side-lights. Both the usual single lantern of the country cart and the two head lamps of the motor-car leave a margin of invisible danger just where the eye can least well perceive it; and much would be gained if carts had to have a simple lantern on either side illuminating the wheel and side, and if motor-car lamps were made so as to throw some of their light back on to the car itself.

The second and lesser need is to throw some light ahead as well as, sometimes, a little to one side so as to steer by the hedge or grass border.

If all vehicles *showed* lights it would frequently be possible to drive without *throwing* a light more than an hour after sunset as well as on moonlight nights, and the pleasure of such drives, or when cycling, is much greater than the same drive with a glaring light. It is far more

Digitized by Google

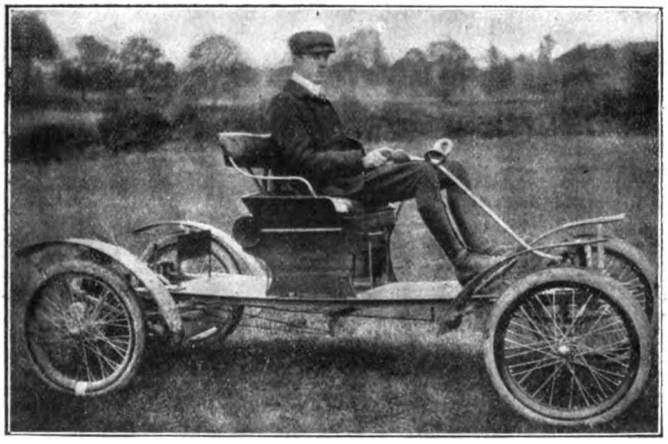
agreeable to travel through a visible country than to grind along in a blurr, even if the pace be somewhat reduced.

On ordinary nights, and even very dark ones, a light of very moderate intensity would be quite sufficient to illuminate the road, at reasonable speeds. The forward ray being as narrow as possible, and only a faint light being thrown to the side of the road, the eyes of the driver would be doubly or trebly as efficient for objects ahead as those same eyes when dazzled by a bright glare on the road and roadside. It is even worth while to abate the light thrown immediately in front of and at the sides of the car, where a faint illumination will reach with sufficient effect. To throw a bright light on to a wall of mist is not only discourteous to other users of the road, but defeats its own object.

While the side-lights will serve very well to illuminate slightly all surrounding objects, the head-light should diverge so little to the right that in normal positions the approaching passenger would be relieved of its glare at a distance of some fifteen yards, and no bright line be thrown on the hedge to the left nearer than, say, ten yards, or anywhere more than some four feet above the ground.

If one of the side-lamps be used to throw a light ahead it should be that on the near side, leaving a glareless space on the off-side for passing purposes. The following, then, are the important facts of the subject :—

An illuminated surface locates the object on which it is better than a bright light.



All appreciation of light is comparative, owing to the adaptability of the pupil of the eye.

The expansion and contraction of the pupil are not instantaneous; sudden change either way means partial blindness.

Vehicles which have width (*i.e.*, not bicycles) should show it.

Travelling is more agreeable, and driving less tiring, in proportion as glare is lessened and the landscape is visible.—Yours truly,

R. R.

Mr. H. E. Tryon, of the Lincolnshire Automobile Club, on his 4-h.p. Orient Buckboard.

ENGLISH V. FOREIGN CARS.

To the Editor of *The Motor-Car Journal*.

Sir,—The users of motor-cars have increased at the rate of at least 25 per cent. the last two years. The output of the British factories is, compared with the number of British users, a comparatively small one, and at the highest estimate their output has not increased more than 25 per cent. On the other hand, in order to meet the big demand for cars, the Continental factories have trebled and quadrupled their outputs, with the result that firms who, three years ago, were sending but 25 cars a year into England are now sending two and three hundred per year to meet the demand in this country. I could mention five French firms who have established agencies in London, who together have sent into England alone this year over 1,200 cars. America, which country, three years ago, at the utmost did not export into this country more than four hundred cars a year, now exports to one firm alone this number apart from the other firms who have London agencies importing cars into this country.

Take the outputs of the various English manufacturing companies, and the figures are ridiculously insignificant in comparison with the figures I have mentioned, which only include a small number of the cars which are being sent into this country. And what does England export? How many cars has England exported into France? How many cars has she sold to Germany? Twenty cars would cover the number she has supplied to America at the very most, and this is apart from other countries which are supplied exclusively from the Continental factories, and the Colonies which also get their supplies from France and America.

The most expensive car in the world, and the car with the highest reputation, comes from Germany. The winner of the Gordon Bennett race came from France. The winner of the great Channel motor-boat race this year was a mixture of Germany and France, that is to say, a German motor in a French hull. A French car won the big International race in America.

What International motor competition has England won? Last year England held the International trophy for motor-boats, and the Gaston-Menier trophy. This year she holds neither, and yet we are told that the British industry is in a much finer position in the world's motor industry than ever it was before. In making this refutation of the statements contained in Mr. Edge's recent letter, I do not do so with the idea of running down or decrying the efforts of England, but I do so in the wish to see England to the front and leading, and I do not think this can be obtained by congratulating ourselves on our present position. None are so blind as they who will not see, and stimulation is required instead of congratulation. There is a need, that grows stronger every day, for England to adopt the policy of progress and keen hard-headed enterprise if she wishes to be in the position which Mr. Edge would have us believe she is now in. And no one would be more happy and no one would welcome the time more gladly than myself to see this, when instead of having to buy motor-cars made in France as the centre of the industry for English requirements, I can procure in England as good a vehicle at as cheap a price as at present is constructed abroad.—Yours truly,

Chas. Jarrott.

DROWSY DRIVERS.

To the Editor of *The Motor-Car Journal*.

Sir,—I was glad to see the "Comment" in the last issue of the *Journal* with regard to the traffic on the highroad from London to Chelmsford *via* Whitechapel, Stratford, Ilford, etc. It was my misfortune one day last week to have to motor along this road; it was my first experience, and it was one I shall not soon forget. The fun—if fun it can be called—began at Aldgate, when for no less than ten minutes we were held up by the police amidst a seemingly inextricable mass of tramcars, omnibuses, haycarts, lorries, and costers' barrows. A little further on another hold-up was encountered, the cause this time being the reconstruction of Bow Bridge. Once over this I had hopes of making up a little of the time lost by a clear run, but it was not to be, for we began to encounter a number of gardeners' carts and wagons which, so far as we could see, were making their way home unattended by any driver. The vehicles were in the middle of the road, and no amount of horn-blowing caused them to change their position. With other vehicles approaching in the opposite direction there was nothing to do but to pass on the wrong side, and as we did so the drivers of the horse-drawn vehicles were discovered to be lying in corners of their carts fast asleep. The trouble was experienced as far as Romford, and on the return journey was, if anything, more pronounced. It was not only the slow farm vehicles which would not budge from the centre of the road—all seemed intent on sticking on the tramlines. To pass them on the right brought us well over on our wrong side of the road, and, tired of tooting the horn, we eventually had to risk passing on the left. Fortunately we got home without accident, but the strain of driving in the dark from Romford to London is such as makes me anything but desirous of repeating it. I fully endorse your suggestion that the police authorities in the districts passed through should undertake a campaign against drowsy drivers, and would further suggest that they would find some useful work in forcing slow-moving traffic to keep to the side of the road instead of the middle, as is insisted upon in London and many other places.—Yours truly,

Rosthern.

THE BLACKPOOL SPEED TRIALS.

To the Editor of *The Motor-Car Journal*.

Sir,—I see there is a proposal to hold another speed trial at Blackpool this year. For my part I think it would be sheer folly, as the public here have had quite enough for one year. When watching the recent trials I heard one fellow say that if the management had had a few donkey races, etc., between the different events it would have been much more interesting, and I have found this view shared by a great many who considered the whole thing badly managed. The waits were too long and the public saw but little racing and never knew who won. The only entertainment for them was to see the cars dash past, and this is too slow to arouse interest a second time.—Yours truly,

Blackpoolite.

BELT TRANSMISSION.

To the Editor of *The Motor-Car Journal*.

Sir,—I respond with pleasure to "Lancastrian's" request in giving such further particulars as I am able of the F.N. car, and for the rest I shall be pleased to show him or others interested the car and special method of belt adjustment. I am informed by the agents that these cars cannot now be obtained, they having ceased to manufacture owing to their very large business in the engines for motor-cycles. This of mine was a special exhibition model. It has two speeds and a crypto silent reverse by pedal; engines are 5-6-h.p.; water-cooled radiators and pump (which has never once fouled in action), and ten-gallon water-tank drum; width of leather belt 2 inches. The method of belt adjustment consists of a system of rocking levers actuated by a powerful screw. F

only know it to be a perfect success, and cannot get out of adjustment unless the key is turned, while the massive construction is adapted to last a lifetime.—Yours truly,

H. Cove.

STEAM CARS.

To the Editor of *The Motor-Car Journal*.

Sir,—In the recent hill-climbing competition held at Bridgnorth, under the auspices of the Wolverhampton and District Automobile Club, my 10-h.p. Turner-Miesse made faster time than any car entered. The following were the actual net times as published in the local press:

		Min.	Sec.
J. B. Dumbell	10-h.p. Turner-Miesse...	1	12 1-5
F. W. Bayliss...	20-h.p. Wolseley ...	1	14 1-5
Captain Owen	10-h.p. Turner-Miesse...	1	16 1-5
C. Sangster	20-h.p. Ariel	1	16 2-5
Wolseley Tool and Motor Co. ...	24-h.p. Wolseley ...	1	22 4-5
Turner's Motor Manufacturing Co.	10-h.p. Turner-Miesse...	1	26 1-5
George Evans	10-h.p. Wolseley ...	1	38 3-5
R. A. Cobb	12-h.p. Star	1	44 2-5
R. M. Shelton	12-h.p. Lanchester ...	1	50 4-5
J. M. Cook	10-h.p. Argyll	2	6 4-5
J. O. Evans	10-h.p. Wolseley ...	2	13 4-5
N. Meakin	10-h.p. Mobile	2	24 1-5
W. H. Evans	10-h.p. Wolseley ...	2	37

Notwithstanding the above, the prizes have been allotted to:—

1. Mr. G. H. Evans, 10-h.p. Wolseley (which my 10-h.p. beat by 26 2-5 sec.)
2. Mr. Cook, 10-h.p. Argyll (which my 10-h.p. beat by 54 sec.)
3. Mr. Sangster, 20-h.p. Ariel (which my 10-h.p. beat by 4 sec.)

Now if the promoters of the competition had any idea that steam cars would be unfairly handicapped as compared with petrol cars, I may fairly claim they should have pointed it out to me or refused my entrance money. Nothing whatever appeared in the rules to indicate that steam cars were to be prejudiced by excessive handicap as compared with petrol cars—although it was reported to me after the competition was concluded that several competitors said we should never again have the opportunity of competing with petrol cars but should be relegated to a class of our own.

I can only assume that my 10-h.p. Turner-Miesse was considered of greater power than the 20 and 24-h.p. Wolseleys and 20-h.p. Ariel, an assumption that the makers of those cars would be somewhat loth to admit, I imagine.

My car, I am prepared to prove if necessary, was a standard 10-h.p. touring car in every respect, exactly the same in every respect as we supply to the public.

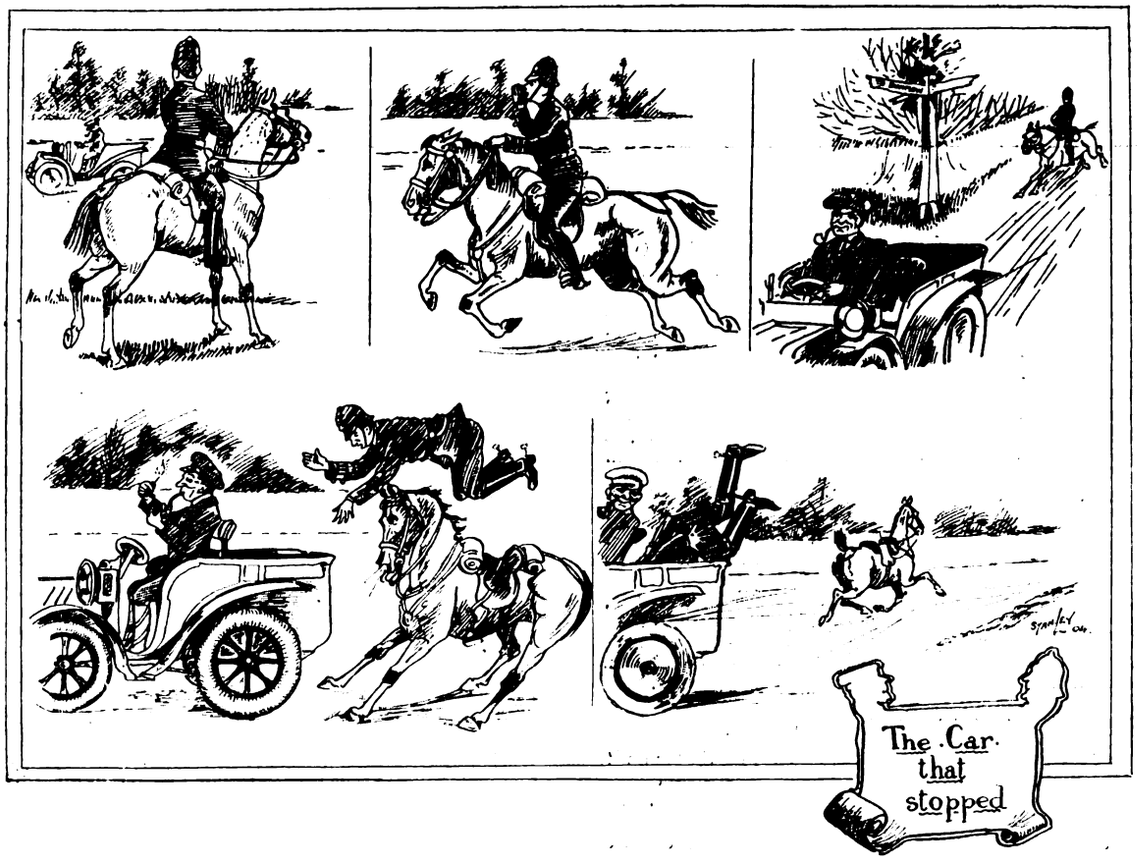
It was not a new car specially built for the contest, but as a matter of fact was a second-hand car that had been driven by a customer last year.

I assumed the competition was held to select the best car at hill-climbing, without any question of steam *v.* petrol, but this does not appear to be the fact, judging by results.—Yours truly,

J. Burns Dumbell.

THE MOTOR-CAR ACT.

To the Editor of *The Motor-Car Journal*.



Sir,—My reason for asking you to insert this letter is that I feel sure there must be others like myself who are ignorantly breaking the law every day, and are therefore as liable to have the same fine inflicted on them as myself. Eleven days after my alleged offence I was served with two summonses to appear at Richmond Petty Sessional Court House. Two days afterwards I sent a letter asking to have the case adjourned. My intention was to apply to the Automobile Club, asking them to take the matter up. This I did by telephone, confirming by letter same day. After a waste of time I was told that the Motor Union could not take the matter up. I did not attend court, having asked for an adjournment, and imagining I was perfectly safe. You can judge my surprise when I received a letter to say I was fined £10 for exceeding the speed limit and 9s. costs, and £3 and 7s. costs for using an unregistered car. In the first instance the excessive speed is not admitted. The timing was of the most crude kind; I was timed, to use the constable's words, "from about here to practically opposite there," and on this ground I was prepared to fight it. The second summons is, I think, more interesting and instructive still: it states that I "did unlawfully use a motor-car at Kew Road there without the same being registered." We pay three pounds a year to use a distinguishing number; the car was out of order, and to prove this I had to call at Messrs. Wass and Co.'s, Richmond, to have a little adjustment done. The number was booked out in the register which we keep for that purpose, and booked in again.

I have since gone into the matter with the officials at Richmond, and find that the Act does not provide for a car being used with a trial number while it is under repair. The Act reads "after completion," which is taken to mean by the officials "after completion by the manufacturer." If you are giving a trial run it is another thing, as it is understood that, unless you have a passenger with you, you are liable to be summoned and fined as I have been.

I counted seven cars passing in Albany Street with manufacturers' numbers on them, and only the driver in the car. I am sorry to trouble you at such a length, but it is highly desirable that agents and others should know exactly what they pay their £3 a year for. Finally, the Motor Union offered to pay the cost of a barrister for an appeal; but, as I am already mulcted to the extent of £13 16s. I prefer to pay this rather than take the chance of increasing the amount to £50 or even more.—Yours truly,

F. Guy Lewin.

The Seddon Tyres.—A Yorkshire motorist asks motorists who have tried these motor tyres to send their experiences.

CLUBS AND ASSOCIATIONS.

AUTOMOBILE MUTUAL PROTECTION ASSOCIATION.

MEETINGS of the Mechanical Transport Committee and of the Council of the Automobile Mutual Protection Association were held at Cecil Chambers, Strand, London, on Friday, October 28th.

The chair at the Heavy Traffic Committee was taken by Mr. Jesse Ellis, and the following resolution was unanimously adopted:—"That this meeting of motor vehicle manufacturers very earnestly represents to the Local Government Board that the commercial vehicle industry of the country, in which branch of automobilism England has so far taken a commanding lead, is being jeopardised by the existing uncertainty in respect of the intended regulations to be made by the Local Government Board under Section 12 of the 1903 Motor Car Act; and this meeting most strenuously urges that the said regulations shall be issued with the minimum of further delay." It was also decided that the Secretary, Mr. Shrapnell Smith, should proceed to Germany to investigate a system of maintaining roads under heavy traffic, which is reported to be very successful in point of economy and absence of noise.

The Heavy Traffic Committee also considered a letter, dated October 25th, from the Technical Secretary of the Automobile Club, in reference to proposed heavy vehicle trials, and it was decided to support such trials. Mr. W. E. Rowcliffe (The Hercules Steam Wagon Company) was added to the Committee.

In the absence of Lord Shrewsbury from town, Mr. Charles Holmes presided at the Council meeting, which took place after the meeting of the Mechanical Transport Committee, when the following resolution was unanimously adopted:—"That the Committee of the Automobile Club be asked to take into consideration (1) the adoption of procedure whereby members of the next Industrial Committee of the club shall be elected by the trade, instead of their being co-opted, and (2) that the matter be referred to a joint committee of the club, the Automobile Mutual Protection Association, and the Society of Motor Manufacturers and Traders." It was reported to the Council that writs had been issued against two members for alleged infringement of letters patent covering radiators of the honeycomb type, but that the actions had been withdrawn. Further instructions were given on this important matter, it being the intention of the Society to watch closely all claims made in respect of this type of radiator.

Messrs. W. G. Campbell (Hunslet Engine Company, Limited), Joseph Keele (Joseph Keele and Co.), and F. P. S. Harris (the General Petroleum Company, Limited), were elected to membership, and Mr. Harris was elected to the Council, making twenty-seven new firms who have joined the association during the last few months.

The next meeting will be held at the Agricultural Hall, Islington, on Thursday, November 24th, this date being selected on account of the Stanley Show, which will then be in progress.

A meeting of the Mechanical Transport Committee will be held on the same day to elect a chairman and deal with any other business.

NORTH-EAST LANCASHIRE CLUB.

THIS club brought a very successful season to a close on the 22nd ult. with a 100 miles non-stop run to Kendal and back. The conditions were those usually imposed at trials of this character, no adjustments of car mechanism being allowed and all stoppages save those arising from traffic being held to disqualify. Restricted to members only, the entries numbered nineteen, and of these eighteen paraded at Billinge End, Blackburn, at half-past nine as follows, the first twelve ultimately being credited with non-stop runs:—

Owner.	Name of Car.	Observer.
Mr. J. Walsh	... 10-12-h.p. Humber	Mr. H. Lonsdale.
Mr. S. Briggs Bury ...	... 12-h.p. Albion ...	Mr. F. L. Heppard.
Mr. W. Smith, jun. ...	... 12-h.p. Albion ...	Mr. A. Barnes.
Mr. P. J. Broadley ...	... 12-h.p. Wolseley	Mr. P. Roberts.
Mr. H. Lonsdale ...	... 12-h.p. Darracq ...	Mr. E. Briggs.
Mr. F. Marwood ...	... 12-h.p. Belsize ...	Mr. F. Hodgkinson.
Mr. R. Spencer ...	... 14-16-h.p. Rex ...	Mr. H. V. Miners.
Mr. H. V. Blake ...	... 15-20-h.p. Belsize	Mr. F. O. Whittaker.
Mr. Wm. Birtwistle ...	... 18-22-h.p. Mercedes	Mr. J. S. Green.
Mr. E. A. Riley ..	... 20-24-h.p. Belsize...	Mr. J. Birtwistle.
Mr. F. Birtwistle ...	... 24-h.p. De Dietrich	Mr. D. Ritzema.
Mr. A. Birtwistle ...	... 22-h.p. Daimler ...	Mr. T. P. Ritzema, Junr.
Mr. W. Livesey ...	... 15-20-h.p. Belsize...	Mr. G. Greenwood.
Mr. A. Marsh ...	... 5-h.p. Rexette ...	Mr. W. Carmichael.
Mr. R. S. Crossley, Jun.	... 6-h.p. Belsize ...	Mr. J. Briggs Bury.
Mr. R. Crossley ...	... 6-h.p. Belsize ...	Mr. H. Gray.
Mr. J. V. Fox ...	... 7½-h.p. Belsize ...	Mr. R. Wilding.
Mr. W. D. Walmsley	... 7½-h.p. New Orleans	Mr. J. Carmichael.

The cars were marshalled by Mr. W. Livesey, and Mr. T. P. Ritzema, jun., acted as starter.

The weather was ideal, bright sunshine and a soft breeze, and, though the greasy condition of the roads to Preston gave drivers some anxiety, the surface rapidly improved, and north of "the proud town" there was little to complain of. To ensure observance of regulations as to speed, a minimum time of 2½ hours was scheduled for the outward journey, the route being through Preston, Garstang, Lancaster, and Carnforth. Most of the cars arrived shortly after the time limit, and after lunch at the Railway Hotel ten minutes was allowed for filling up and lubricating, this having to be done in the presence of the observers.

The return journey was commenced at half-past two, and when the observers handed in their reports to the Hon. Sec. at the Half Way House, Samlesbury, on the conclusion of the run, it was found that an unexpectedly large proportion of cars—twelve out of eighteen—had completed the run without a stop. As the club had promised gold medals to those who qualified, the treasury officials came in for a little pleasant chaff, as report after report announced "another winner," but the treasury will stand the strain. The cars carried a full complement of passengers, and the run was voted one of the most successful in the club's history. The 20-24-h.p. Belsize was very creditably driven by Mrs. Riley, the well-known North-East Lancashire lady motorist, whose report was devoid of even compulsory stops for traffic.

NORTHAMPTONSHIRE.

THIS Club inaugurated its winter session with a succesful smoking concert at headquarters—the Great Northern Hotel, Peterborough—on Friday evening of last week. About 150 members and friends were present. Councillor Richard Winfrey presided. The following motorists were amongst the company:—Dr. Benson (Market Deeping), Dr. F. Husband (Crowland), and Messrs. W. Walshaw, W. J. Deacon, C. Godfrey, F. Redhead, Brodie, A. J. Sole, W. Southwell, T. Woodman, A. Woodman, W. Barrett, J. Simpson, D Gray, J. H. Carter (Market Deeping), T. A. Morris (Bourne), O. Rowe, J. Montgomery, H. Ruff, R. Parris, E. H. M. Wood, W. Barrett, J. Simpson, F. Whittorne

G. L. Julyan, and R. Impey. In the course of his remarks the Chairman touched upon the question of Universal Lighting, and mentioned that if his proposition had been brought on after the recent accident to the Duke of Connaught a system of general lighting would, probably, have been enforced by the local County Council. Arrangements had been made for a series of lectures on motoring during the winter, and the first discussion, on the petrol engine, would take place on November 11th. To make these gatherings interesting different parts of the motor would be explained week by week, and some trials for motor-cars and cycles were under consideration. In the concert-room was displayed an amusing contrast, illustrative of the ancient and modern. The ancient was the first safety bicycle introduced into Peterborough—a truly antediluvian specimen, on which tradition states Mr. Bob Julyan initiated the earliest practitioners of the wheel into its seductive mysteries. By its side was a first-class up-to-date specimen of the 1904 "Bat" motor-cycle, of the type which won the recent contests at Blackpool. At the close of the proceedings a hearty vote of thanks, proposed by Mr. W. Southwell, and seconded by Mr. E. H. Wood, was accorded to Councillor Winfrey for his services in the chair.

WOLVERHAMPTON.

THE results of this club's recent open handicap were as follows:—

Name of owner.	Make of Car.	Result.
Evans, G. H.	10-h.p. Wolseley	1st.
Cook, J. M.	10-h.p. Argyll	2nd.
Sangster, Chas.	20-h.p. Ariel	3rd.
Bayliss, F. W.	20-h.p. Wolseley	4th.
Shelton, R. M.	12-h.p. Lanchester	5th.
Cobb, R. A.	12-h.p. Star	6th.
Dumbell, J. B.	10-h.p. Turner-Miesse steam	6th.
Evans, J. O.	10-h.p. Wolseley	8th.
Owen, Henry	10-h.p. Turner-Miesse steam	9th.
Wolseley Tool and Motor-Car Co., Ltd.	6-h.p. Wolseley	10th.
Wolseley Tool and Motor-Car Co., Ltd.	24-h.p. Wolseley	11th.
Meakin, Nelson	8-10-h.p. Mobile	12th.
Turner's Motor Manufacturing Co., Ltd.	10-h.p. Turner-Miesse steam	13th.
Evans, W. H.	10-h.p. Wolseley	13th.

The results of the Club Handicap were as follows:—

Evans, G. H.	10-h.p. Wolseley	1st.
Sangster, Chas.	20-h.p. Ariel	2nd.
Bayliss, P. S.	8-h.p. Panhard	3rd.
Bayliss, Edwin	7-h.p. Panhard	3rd.
Bayliss, F. W.	20-h.p. Wolseley	5th.
Bishop, F. C.	7-h.p. Star	6th.
Cureton, Thos.	10-12-h.p. Sunbeam	7th.
Mills, T. T.	10-12-h.p. Sunbeam	8th.
Evans, J. O.	10-h.p. Wolseley	9th.
Dumbell, J. Burns	10-h.p. Turner Miesse Steam	10th.
Marston, John	16-18-h.p. Sunbeam	11th.
Davis, J. W.	7½-h.p. Wolseley	12th.
Bath, H. J.	9-h.p. James and Browne	13th.
Evans, W. H.	10-h.p. Wolseley	14th.
Mills, Arnold	12-h.p. Sunbeam	15th.
Payne, S. B.	4½-h.p. De Dion	15th.
Lisle, J.	7-h.p. Star	17th.
Gattis, T. G.	10-h.p. Enfield	18th.
Marston, John	16-h.p. Sunbeam	19th.
Corker, F. B.	12-h.p. Sunbeam	20th.
Pratt, E. C.	6-h.p. Mobile	21st.

The formula upon which the foregoing resul were obtained is—

$$\frac{\text{Time} + \text{H.P}}{\text{Total weight.}}$$

MOTORS AND THE LAW.

MR. C. A. MONTAGUE BARLOW, LL.D., M.A., barrister-at-law, lectured on Thursday, the 27th ult., at Lincoln's Inn Hall, London, before the Solicitors' Managing Clerks' Association, upon the subject of "The Law of Mechanical Traction on Highways," Sir Albert Rollit, M.P., presiding.

Mr. Barlow, in the course of his lecture, said that the law with regard to the matter was in considerable confusion, and many sections of the various Acts relating thereto were difficult of construction. After a review of the legislation upon the subject from the year 1861 onwards, he said that the Locomotives on Highways Act, 1896, now to be cited with the Motor Car Act, 1903, as the Motor Car Acts, 1896 and 1903, was the charter of the motor-car, and first exempted motors from the restrictions of the Locomotive Act, such as the presence of an attendant twenty yards ahead, the speed limit of two and four miles an hour, and so on. But engine-owners and the public were not satisfied, and, as the result of a Select Committee, a further Act was passed, and ultimately the Motor Act, 1903, which came into force on the 1st January last. This Act was to be read with the Locomotives on Highways Act, 1896, as already stated. The definition of motor-cars was, generally speaking, to be the same as that of light locomotives in that Act, but the Local Government Board might make regulations increasing the maximum limits of 3 and 4 tons allowed by the earlier Act. The provisions of the Act dealt mainly with three points. The first of these was driving on the highways and the rate of speed. Four offences were constituted, viz., driving "recklessly or negligently, or at a speed or in a manner which is dangerous to the public, having regard to all the circumstances of the case," including the condition of the highway and the amount of the traffic. This clause would certainly lead to difficult cases of interpretation in the Courts. A constable might arrest anyone he *saw* driving recklessly if he refused his name and address, or if the motor was not carrying the marks of identification required by the Act. Motors were to stop if, owing to the car, any accident happened to horse, person, or vehicle, and the driver must, if asked, give his name and address under the penalty of a £10 fine, with a month's imprisonment for the third offence. The speed was fixed at twenty miles an hour, with power to the Local Government Board, on the application of the local authority, to limit speed in places or "controls" to ten miles an hour. There was to be no conviction on the evidence of one witness merely. Notice boards were to be erected at the special localities or "controls." The Local Government Board had power to restrict motor traffic, or the use of any particular kind of motor, on narrow roads less than 16 feet wide, or any other road where they considered such traffic dangerous. In the second place cars were to be registered, and in the third every driver was to be licensed. The Act was only to remain in force for three years. The one great storm centre, so to speak, around which the thunder of future litigation would rage was to be found in the following section of the new Act:—"If any person drives a motor-car on a public highway recklessly or negligently, or at a speed or in a manner which is dangerous to the public, having regard to all the circumstances of the case, including the nature, condition, and use of the highway, and to the amount of traffic which actually is at the time, or which might reasonably be expected to be, on the highway, that person shall be guilty of an offence under this Act." What were these circumstances? They would be the width of the road, frequency of traffic (carriage and foot), straightness or otherwise of the road, and the number of side roads or gates opening on it. If the road was winding, or obscured by trees, or ran through a well-peopled district or town, magistrates might easily find that these circumstances made driving dangerous, even at so low a rate as, say, eight or fifteen miles an hour, according to the limit; on the other hand, no penalty could be imposed so as to prevent the full maximum speed limit being allowed. In Smith v. Boon, decided on the old Act in 1901, the justices convicted the driver of a motor-cycle, who was proceeding down Esher High Street at eighteen or twenty miles an hour, of driving at a speed greater than was "reasonable or proper, having regard to the traffic on the highway." There was no evidence that any vehicle or person was interfered with or incommoded. The divisional court upheld the conviction, it being held that the words "having regard to the traffic on the highway" meant having regard to the traffic on the road, and not having regard to the traffic in the immediate vicinity of the motor. This was followed in Mayhew v. Tutton, where a constable saw a motor-car driven by the appellant, Mayhew, coming at a "terrific" speed down Red Hill, on the Oxford road, near Denham. The constable held out his arms; the appellant could see him on turning a corner 340 yards away, but did not pull up until sixty yards beyond where he stood. No evidence was given that there were any passengers or vehicles on that part of the road, or that anyone was endangered. The justices convicted on the ground that the appellant was driving to the common danger of passengers, and that it was not necessary to prove that any passengers were endangered. This was upheld in the divisional court. The result of these decisions appeared to be (1) The driving must be, in the opinion of the magistrates, such as, having regard to all the circumstances of the case, could be called "dangerous." It was not clear in either of the cases what elements justices considered constituted the driving in each case dangerous or the speed excessive. (2) It was not necessary to constitute dangerous driving to prove that any particular person or vehicle was in fact placed in danger at the actual moment. (3) The standard to be taken was the ordinary traffic of the road. If the speed or method of driving could be called "dangerous" in view of the normal state of traffic, it would be no answer for the driver to say that at the particular moment there was no traffic in sight. A speed of nineteen miles an hour might be dangerous driving down Kensington Grove in the middle of the day, having regard to the normal traffic there; nor would it be any the less "dangerous" within the meaning of the Act on the ground that at that particular moment there happened to be no one else on the road.

THE INDUSTRIAL USES OF ALCOHOL.

ON Friday of last week Dr. W. R. Ormandy, of Warrington, gave his lecture on "The Industrial Uses of Alcohol" to the members of the Lincolnshire Automobile Club. Mr. F. H. Livens, president of the local Chamber of Commerce, presided.

The lecturer dealt with the attitude of the permanent officials of the Government, and some of their mistaken ideas on the question. The Finance Act of 1902 did allow the duty on alcohol to be removed, but the restrictions were so many that so far only six had applied for the removal of those restrictions. Sympathetic measures were very important in the early days of an industry, and in Germany the industrial alcohol movement had been so well assisted by the Government that a great industry, paying eleven millions in wages per annum, had sprung up. He likened the present attitude of the country to Huxley's "Man and the Microscope," who saw only the leaf that was developing, and was unaware of the tree, the broader issues. A movement was, however, springing up

Digitized by Google

started, he believed, by the Manchester Chamber of Commerce, who realised the great usefulness of alcohol for fuel, lighting, heating, and power. He had been to Germany to study the question, and found that we had some very erroneous ideas as to price, what alcohol could be mixed with (it could not be mixed with petrol, for which alcohol was not a solvent), and from what it could be made. The production in Germany was 300,000,000 litres per annum, of which 121 millions were used for industrial purposes—20 millions of that being for chemical industries, manufacturing varnish stains, solvents for various things—and 19 millions for vinegar. The remainder went for the purposes of light, heat, and power. We had, therefore, a great leeway to make up. In Germany there were 27,000 lamps made in three months, with incandescent mantles, giving a beautiful light of 40 to 60 candle-power, yet without heat, smoke, or smell. They were safe, and used in villages and on the farms in a far better and safer way than paraffin, yet at a third of the cost. The subsidiary trade, or side issues, such as bottle making, distributing, heating, and cooking stoves, used economically by even the very poorest people, brought in a big revenue. These stoves could be lit or extinguished at a moment's notice and were without smell. Another thing was that 2,700 engines up to 25-h.p. had been made and sold, and both ordinary engines and motor-cars were being successfully driven by alcohol. The price question was then dealt with, and it was shown that with potatoes at a pound a ton alcohol could be produced at a shilling a gallon. Land was used in Germany that was fit for nothing but potatoes, and all they troubled about was cheap, rough culture, getting the biggest crops possible, quality being immaterial. All went to the distilleries, and if the potatoes went bad it made little difference. The German Government had helped the farmers in adapting laws to their needs, holding peripatetic exhibitions, giving prizes for alcohol lamps, and in other ways. What happened may be summarised in this way. The potatoes were grown on poor land in a rough manner, turned into alcohol on the spot, and the residue, the schlempe, used for feeding cattle. He saw on one farm no fewer than 3,000 cattle, all fed on this schlempe, of which they had 16 gallons a day, and 6 lbs. of clover, 6 of molasses, and 40 of potatoes when being fattened. In this way the land was again manured, so that a farmer would grow his potatoes, make his alcohol, some of which he used for heating, lighting, and power; and he fed his cattle, of which he could keep enormous numbers, on what was left from the alcohol. An important phase of the question was, he thought, that if in England we could, in time, of course, go for the enemy and smash them up, instead of having to worry about getting plenty of food into the country, we should be in an enviable position. He was certain that if we adopted potato culture for alcohol we should almost be able, in time of war, to provide enough food from potatoes.

In the discussion which followed, Captain J. A. Cole, Colonel J. S. Ruston, and Messrs. C. W. Pennell, J. Jekyll, Arnold Lupton, and A. E. Collis took part. In reply the lecturer said three tons of potatoes was equal, for alcoholic purposes, to a ton of grain. We sent £4,000,000 to America each year for paraffin. Alcohol for engines had to be used in a different way to petrol. In the first they had to heat the jacket, and in the other to combat the heat generated. In the Manchester district they had a good one-cylinder alcohol engine running, and would soon have a three-cylinder one in use.

APPEALS BY MOTORISTS.

At the Dublin City Sessions, before the Recorder, the Hon. Walter Guinness appealed against the decision of Mr. Drury, Divisional Magistrate, imposing a fine of £10 upon him for alleged reckless and furious driving of his motor-car in Leeson Street. After a long hearing, the Recorder said if the case had been brought under the 9th Section, which prohibited a higher speed than twenty miles an hour, he would ask for evidence on the part of the defendant. The case was brought, however, under the 1st Section, and he could not hold under that Section that Mr. Guinness was driving recklessly and at a speed dangerous to the public, having regard to all the circumstances of the case, because it was clearly proven that the thoroughfare was entirely free from traffic at the time. Speed was not necessarily evidence of negligence; it all depended on the circumstances; and there was no evidence in this case that the public safety had been endangered.

Thomas Faulkner, of Fairford, appealed at the Oxford County Quarter Sessions against a conviction by the Justices of the Banbury and Bloxham Division, the respondent being Mr. Thomas Augustus Motion, the High Sheriff of Warwickshire. Mr. Cecil Walsh and Mr. Davidson (instructed by Mr. Claude Fortescue, Banbury) appeared for the respondent, and Mr. A. Moresby White and Mr. Ames (instructed by Messrs. Staplee Firth and Co., London) represented the appellants. After a long hearing the Bench did not see any reason for disturbing the decision of the court below. The appeal was dismissed with costs.

BUYING A SECOND-HAND CAR.

E. T. Holbrow, trading as the Earlsfield Motor and Engineering Works, sued Messrs. Clements, Knowling and Co., of Brentford, for £50, the balance of cost of a motor-car sold by him to defendants. The action arose out of a claim formerly before the Court, in which Messrs. Clements, Knowling and Co. were plaintiffs, and sued Mr Holbrow for breach of the contract. The case was tried before a jury, and after hearing the evidence His Honor, in directing them to the main points, told them that he was glad they had been summoned, because the responsibility of the decision was thrown on them, and not on him, although only two out of the five had said they were capable of dealing with the expert evidence. The jury retired to consider their verdict, and on returning, after a short absence, said they found in favour of the plaintiff. His Honour said he concurred in their verdict, and gave judgment for plaintiff.

CASES AGAINST MOTORISTS.

Place.	Summoned for	Fine.
Shap (Carlisle)	Not giving audible notice of approach	£2, etc.
Walton.....	Driving motor wagon without rear light	5s.
Dartmouth	Refusing to stop when requested	£1.
Plymouth.....	Furious driving	Dismissed.
Malvern	(1) no licence; (2) no rear light	(1) £1; (2) 10s.
Newbury	Reckless driving	£10.
Dunblane	Driving motor-car on a scheduled road	£3 3s.
Canterbury.....	No rear number	£1, etc.
Huntingdon	Driving to common danger	£4, etc.
Manchester.....	Not producing licence	20s., etc
S. W. London	Owner of car failing to assist identification of driver	£5.
Mortlake.....	No light	10s., etc.
Penrith.....	Lad of 14 years for failing to produce licence	20s., etc.
Kingston	Driving to common danger	£3, etc.
Bow Street	Exceeding ten mile limit in St. James' Park	40s., etc.
Perth	Beyond legal limit	£7 10s.
Brentford.....	Furious driving	£10.*
Dumbarton	Driving furiously and knocking down three men	A month's imprisonment.
Kirkham	Driving beyond legal limit	£10, etc.
Bow Street (London)	Driving in Green Park beyond ten miles an hour	£3, etc.
Westminster	Driving without a licence	£10, etc.
Kingston	Dangerous driving	£3, etc.
Cranborne	Dangerous driving	£3 9s.
Clerkenwell	Reckless driving	40s., etc.
Rushall (Staffs)	Stopping motor-van on top of bridge	20s., etc.
Dublin	Furious driving	40s., etc.
Hove	(1). driving recklessly; (2) failing to stop after accident	(1) £2 10s.; (2) £5, etc.
Littlehampton	No light	£1, etc.
Keswick	Furious driving	Dismissed.

POLICE TRAP.

A nicely devised trap exists on the Clifton Drive, St. Anne's. Several motorists have lately been caught therein.

CONVICTIONS QUASHED.

At the Maidstone Borough Quarter Sessions the case of Gale v. the Justices of the Borough of Maidstone has just been heard. It was an appeal by the driver of a motor-van against a conviction for negligent driving. P.C. Baker deposed that on June 25th he was on duty in High Street. About ten minutes to nine he heard a crash, and found Messrs. Style and Winch's motor-wagon on the pavement about fifteen inches from the bar door of the Queen's Head public-house. The railings of Mr. Winterhalter's sunblinds had been knocked down. Witness spoke to the driver, Dan Gale, who said that owing to the greasy roads the brakes failed to act, and thus caused the wheels to jump the kerb. Dan Gale, the appellant, said on the night in question the roads were greasy, and he shut down steam to get round the corner. The steering arrangement, however, jammed, and he could not get it to act till the van was on the pavement, which was when he put on the brake. He was driving at the rate of three or four miles an hour. Had the street been dry the engine would have stopped, but as the street was greasy it skidded quite four feet. The conviction was quashed, and no order was made as to costs.

Mr. Ralph Dickerson, of St. Andrew's Road, West Kensington, was convicted on the 19th of May, at Hastings, for driving a motor-car in Robertson Street, and in a manner which was dangerous to the public, and he was fined £10 and £1 4s. 6d. costs. Mr. Dickerson appealed against this conviction to the Quarter Sessions, held at the Sessions Court, Town Hall, Hastings, on Friday, October 28th. Mr. A. M. Labouchere, instructed by Mr. Staplee Firth, appeared to support the appeal, and in the result the conviction was quashed and the appeal was allowed.

THE

Motor-Car Journal.

VOL. VI.] LONDON, SATURDAY, NOVEMBER 12, 1904. [No. 297.

Published Weekly by CORDINGLEY & CO., 39 & 40, Shoe Lane, London, E.C.

COMMENTS.

IN rural districts, even more than in urban localities, where the presence of traffic prevents high speeds being obtained, the motor fire engine is likely to be regarded as the main element in the constitution of any properly equipped brigade. An evidence of its utility has occurred on the south coast, where, as is well known, the Brighton Fire Brigade has a motor fire engine. A fire broke out at Lewes which threatened to extend to other buildings and become uncontrollable. Help was asked from the neighbouring towns, Brighton being among the number. The superintendent at once despatched his motor fire engine, which arrived at the scene of the fire—eight miles distant—in twenty-five minutes. Once at Lewes it rendered good service. The point which we would urge, however, is that automobilism introduced into the fire brigade service will add considerably to the efficiency of the work in the country districts, where the time occupied in getting from large towns to distant places has often enabled fires to get a good hold of buildings before the arrival of the firemen.

◆ ◆ ◆

Some Notable Hills.

REPLYING to correspondents who have asked us as to some of the steepest hills for the trial of motor-cars, several occur to mind. Dashwood Hill, near High Wycombe, with its rise of 219 ft. in 3,350, is famous. One-third of its distance has a gradient of 1 in 10·37. The average gradient of Porlock Hill, in North Devon, is 1 in 6. The length of Westerham is 2,942 ft., the average gradient being 1 in 9·4. Between York and Bridlington is Garrowby Hill, which begins with a rise of 1 in 14, which, after increasing to 1 in 8, gets even more difficult of ascent. We shall be glad to hear from any of our readers in the locality the gradient of the Gas House Hill, near Norwich.

◆ ◆ ◆

The Blackpool Trials.

AS we were able to announce by means of a Supplement to our last issue, the Blackpool speed trials have been abandoned for the present. This decision was arrived at by the Corporation of the town owing to the delay in receiving assurances of the presence of a sufficiently representative number of racing cars. No further motor races, therefore, will take place at Blackpool until next spring, by which time the Promenade will have been further extended another thousand yards. This addition will give the Blackpool track a pre-eminence among motor racing tracks.

◆ ◆ ◆

Hotel Charges.

BEFORE anything is settled, we would, however, urge one point which has occasioned much comment and correspondence at recent motor meets. We refer to the extravagant notions which hotel proprietors seem to entertain as to the wealth of those who own cars. This has frequently reached a point quite out of keeping with modern ideas, and even the richest men do not care to feel that they are being fleeced to make a hotel keeper's profits. Because it happens that motorists decide to help the prosperity of a town by holding a series of races therein, is no reason why they should be taxed beyond the rates charged to ordinary visitors. They have to pay for the storage of their vehicles, and are generally liberally-minded with regard to charges on such occasions. But the ruinous prices charged by some hotels will produce a reaction, and no meets will be held until a large number of the local hotel keepers agree to regard motorists as human beings with ideas as to the value of the service received, and not as sheep to be shorn.

◆ ◆ ◆

Railway and Motor Cars.

A MOTOR-'BUS service between the commercial town of Wolverhampton and the picturesque, rugged district of Bridgnorth has just been established by the Great Western Railway Company. This will also serve the market-gardeners of the locality in getting their produce to the markets, and the Mayor of Bridgnorth has suggested a special service on market days, while from the Wolverhampton end of the journey comes the proposal for a theatre 'bus, so that the residents of other places may be able to enjoy amusement in that town without staying overnight. Doubtless other developments will be regarded by the railway company, for the journey can now be accomplished in an hour and a-half, as compared with the three hours taken up by the trip by train.

◆ ◆ ◆

Harrogate Organises.

THE Yorkshire Club is going ahead and developing into a powerful organisation likely to be of considerable service to owners of automobiles in the county of broad acres. Elsewhere we record a social gathering with which the winter season has been opened. Various centres in Yorkshire now possess their clubs, and at Harrogate, as the result of a meeting of local motorists and owners of motor-cars, it has been decided to form an automobile club for that town. A committee has been appointed, with Dr. F. N. Ozaune as chairman, to organise the association, and also to find out the best means for opposing the application of the Harrogate Corporation to the Local Government Board for the enforcement of an eight miles an hour limit in the borough. Doubless affiliation to the Yorkshire Club will follow, thus enabling the motorists of Harrogate to have the influence and experience of those of other parts of the county to guide them in their encouragement of automobilism.

◆ ◆ ◆

Licences for Carbide of Calcium.

WITH reference to the granting of licences for the storage of calcium carbide by local authorities under the Petroleum Acts, it has been represented to the Secretary of State for the Home Office that the removal of the limitation of quantity to be contained in any one vessel would be of advantage to the trade. We are glad to announce that the Secretary is of opinion that this limitation may safely be removed, inasmuch as there is, in his view, no increase of danger in the use of larger vessels, either in conveyance or storage, provided that the vessel is strong in proportion to the weight of its contents. He also wishes to bring to the notice of local authorities the fact that, whereas it is desirable to insert some condition in the licences as to the carbide

Digitized by Google

being rendered inaccessible to unauthorised persons, it is seldom necessary to require that each containing vessel should be fitted with a lock.

◆ ◆ ◆

Farm Produce.

BOARDS OF GUARDIANS in the metropolitan area seem well inclined towards the automobile, and, following the lead of Edmonton, the Poor Law authority for Poplar is now purchasing a motor-wagon and trailer for the conveyance of produce from their farm at Laindon Hills, in Essex, to London. It is calculated that the cost of conveyance from the farm to London will be no more under the new system than the rates now charged for taking it from the farm to the railway station. Special facilities having been refused by the railway authorities, the guardians have been led to adopt the new method of transport for reasons of economy.

After passing through the Water Splash—Something Wrong.

◆ ◆ ◆

Technical Instruction.

IN Ireland technical instruction in connection with motor-cars and automobilism generally seems to be making considerable headway, and at Bray no less than fifteen students at the local technical classes presented themselves for examination, all passing with credit. Curiously enough, the first place was taken by a police-constable, whose enthusiasm for motoring has apparently taken a very practical form; in fact, his success would seem to suggest that here is a new department of educational advance for the policemen of some of our Surrey districts. At the Pembroke Technical Schools in Dublin, too, automobile instruction is being regarded with favour, and the purchase of a motor-car for instructional purposes has been approved by the responsible committee, while Mr. McTaggert has been good enough to present a complete set of bicycle engine castings and parts to the local technical school, with a view of assisting the motor engineering classes in that institution. These developments are really on the lines that we suggested last week in connection with the technical instruction work in London, and would seem to indicate that Ireland, which received motorists in such a sportsmanlike spirit in 1903, is now seriously tackling the more technical side of the matter.

"Highway Robbery."

PROSECUTING some drivers of steam lorries at Ormskirk the other day, Mr. R. Glover, on behalf of the Lathom Urban District Council, urged that they had been guilty of a new form of highway robbery. The defendants were drivers for the Hercules Motor Wagon Company, and were summoned for having, on the 3rd August, at Lathom, stolen water from the District Council's main, and also for having wasted water. The defendants pleaded guilty to the first, and not guilty to the second charge. The men were each in charge of a steam wagon travelling from Southport to Manchester, and at Westhead they put a standpipe they carried with them to one of the council's hydrants and took about 500 gallons of water. They left the water running for about three hours. The defendants said their tanks would only hold eighty gallons. The bench imposed a fine of 10s. and costs in each case, and allowed two guineas costs outside the court costs.

◆ ◆ ◆

A Problem for the Near Future.

THIS case opens up another question for consideration by the organisations which are looking after the interests of users of motor-lorries and heavy vehicles generally. For, unless supplies of water are readily available in country places as well as town localities, the difficulties of drivers will be great indeed. Of course we do not defend the wastage which evidently took place, if the result is to be accepted as the rightful consequence. But, just as horses have been provided for in this respect, so motor vehicles will have to be considered in the future. The subject is not a mere local one, but must be regarded from the national point of view. The cost of registration and licensing should include all water supplies of this kind that may be necessary, otherwise the cost of checking the quantities taken from various sources would probably prove prohibitive to any reasonable settlement.

◆ ◆ ◆

Commercial Literature.

GREAT advance has been made of late years in the form and matter of the circulars and price lists issued by firms in the automobile business—a reflection that occurs on glancing through a little pamphlet entitled "Automobile Topics," issued by Messrs. J. B. Ferguson and Co., of Belfast, who have entered into the motor-car trade with energy and spirit. Only a few blemishes in the ways of spelling the names of certain well-known motorists detract from the merits of the booklet, which should do much to convince of the facilities of the firm for assisting motorists passing their way. We shall be glad to receive copies of similar publications issued by firms catering for the wants of those who travel by automobile.

◆ ◆ ◆

The Death of a Dog.

IN a case heard at Shap police-court the defendant, a motorist, who was charged with negligent driving, said he did what his judgment prompted him to do under the circumstances. In order to avoid killing the dog and endangering the occupants of his car, he guided the car so that the body of it passed over the dog. It was not compulsory for him to pull up the car even for a dog if such action endangered the life of the passengers. Had it been a child he would have sacrificed himself and the car. This raises a nice point, for the passage of the car over the body of the dog seems to have wrecked the life of that animal. The principal witness for the prosecution observed that the dog was running beside a trap in which the owner was riding. Surely it was his duty to either have kept the creature behind the vehicle or on the other side of the trap. If, in addition to the width of their vehicles and the necessary space for clearance, drivers of horse-drawn vehicles are also to claim another foot or two of the road, the highways would become impassable. No motorist would deliberately run over a dog, for, apart from kindly feeling, there is the danger that arises from contact with obstructions on the road.

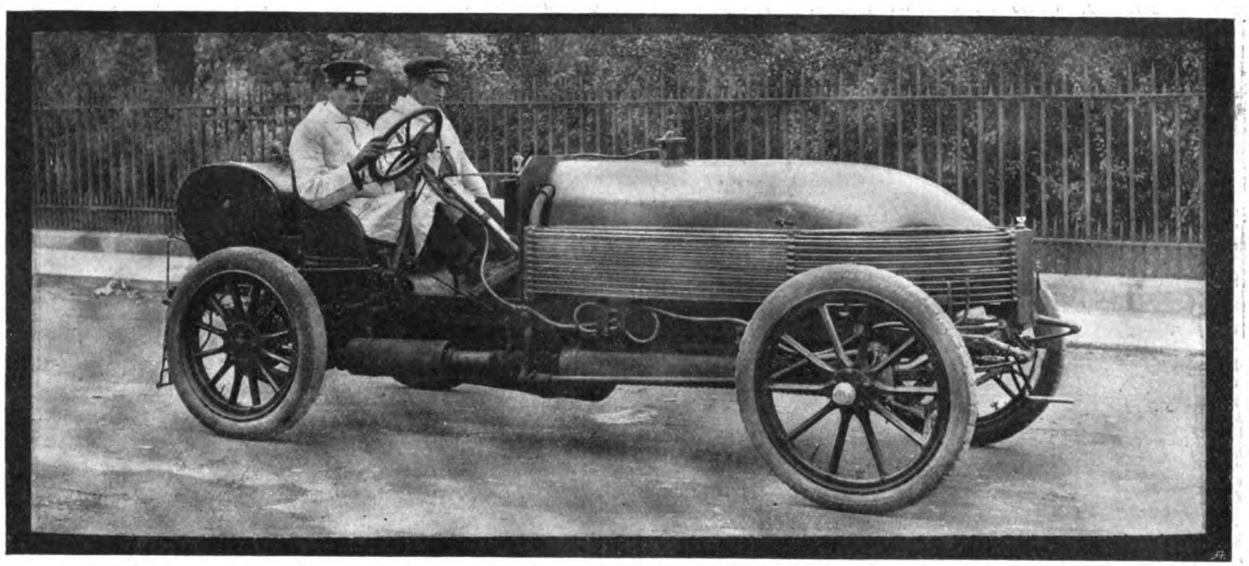
The Courtesies of the Road.



FOR exhibition in the motor houses of members and, we hope, in other places where drivers of motor-vehicles congregate, the Scottish Automobile Club has prepared a notice, mounted on stiff cardboard, giving some hints with regard to the courtesies of the road. There is no doubt that a careful regard to these warnings on the part of drivers would do much to engender good feeling on the part of the public to automobiles and their owners; and the idea might well be imitated by clubs and organisations on this side of the Tweed. Motorists are advised to give the maximum space possible when passing cyclists and horse-drawn vehicles. When passing restive horses, or—it might have been added—nervous drivers of such animals, to use the utmost consideration, even to stopping the engine, if necessary, although no hand may have been held up. Nearing roadside residences, or when passing through towns and villages, drivers should go slowly, so as not to fill houses and cottages with dust—a piece of consideration that would be appreciated throughout the country.

◆ ◆ ◆

Motor-car Service in Jamaica.

PARTICULARS are to hand of a motor-car service for the carriage of mails and of passengers—in fact, to act as a kind of feeder to the railway in Jamaica. Mr. Middleton is responsible for the proposed service, and he intends to place on the road a couple of steam motor-cars, one of which will start from Sav-la-Mar at 3 a.m., reaching Kendal to meet the early train to Kingston. It will then await the arrival of the evening train back to Kendal, and return to Sav-la-Mar the same evening. The vehicles will run by way of Balaclava and Santa Cruz in order to increase the postal facilities at those places. Originally it was intended to have a service from Kingston to Port Antonio, on the north coast, but this idea has been abandoned owing to the number of rivers that would have to be crossed. The fare to be charged for the service from Sav-la-Mar to Kendal, a distance of 80 miles, is equivalent to 16s., but the saving of time and also of expense as compared with the system now in vogue will doubtless make the new facilities popular among residents in Jamaica.

Mr. Arthur Macdonald and his mechanician, Lewis, on the six-cylinder Napier Racer which attained a speed of over 76 miles per hour in the recent Hill Climbing Competition at Gaillon.

Motor-Boating on English Lakes.

OUR English lakes should have a fascination for those who take their pleasures on the water in motor-boats. Already it has been suggested to hold a motor-boat gathering on Lake Windermere next year, and there seems everything within the vicinity to make such a meeting a pleasurable success. Owners would be able to get their boats into the water safely and with little trouble. There is a large crane at the water's edge, which renders it possible to lift the boat from the railway truck and drop it direct into the water. The lake itself is large enough to enable a twenty mile course to be marked out, while the numerous hotels on the banks could afford accommodation to the great crowd of visitors that would be sure to be attracted by the event. The natural attractions of the lakes are great, and if the delights of motor-boating could thus be enjoyed during the pursuit of motor-car touring the joys of the pleasure-loving motorist should be complete.

◆ ◆ ◆

Imports.

IN calling attention to the official return of the imports of automobiles into our ports from foreign countries we would remind readers that these are based upon information derivable in the country from which they are shipped to British shores. Hence the non-appearance of Switzerland in the list, and the apparently small export from Germany is accounted for by the fact that large numbers of the cars of German make reach us *via* Belgian and Dutch ports.

◆ ◆ ◆

In Australia.

GREAT interest is being taken in the Colonies in the question of opening up the agricultural settlements and other communities removed from railway tracks. Doubtless the provision of automobile services for the transport of goods would do much to promote the prosperity of the countryside, and the Belgian Consul-General for the Australian Commonwealth has communicated to his Government the fact that inquiries into the matter have lately been frequent. Unfortunately for the colonist the import duty on motor-cars is heavy enough to restrict the trade in automobiles, save for pleasure purposes—a factor in the situation which cannot be overlooked.

◆ ◆ ◆

Boys and Cars.

TWO boys charged with placing obstructions in the way of the automobiles in Montreal have been required to give bonds for two hundred dollars each to keep out of mischief for a year. The sentence is not too severe considering the risk to human life involved in such pranks, and something of the kind may yet be required in some English localities where chil-

Digitized by Google

dren congregate in groups in the roadway to pester and annoy motorists passing their way. Near Birmingham a sad accident has just occurred owing to the passengers in a car attracting boys to swarm thereon by the distribution of a few coppers. As soon as the vehicle was started one lad was knocked down, a mishap that naturally occasioned much sorrow in the car and indignation in the village. The further boys are kept from cars the better for both the boys and the cars.

◆ ◆ ◆

Motor-car Houses.

GREAT is the influence of the automobile in many subsidiary directions apart from the development of the engineering industry, which it has directly influenced. A great many firms that have hitherto been associated with the construction of horticultural buildings and the like, coach houses, and iron and wood buildings generally, are now studying the requirements of the owners of motor-cars for the stabling of their vehicles. Some, more practically inclined than others, have become possessed of automobiles in order to know from actual acquaintance the various fitments that add to the convenience of the motor-car shed. So that the automobile, which is in many ways displacing the horse, is not wholly without hope for the builder of stables and coach-houses who adapts himself to the changed circumstances of the time.

◆ ◆ ◆

Events in India.

FOLLOWING the information given last week with reference to the forthcoming events in India comes the news that the Maharaj Kumar Tagore has offered a trophy to be competed for under the auspices of the Automobile Association of Bengal. A special committee has been elected to formulate the terms of the competition, and consists of Messrs. E. J. Oakley, F. Marsh, and J. H. H. Rolfe. It is proposed to make the competition an open one, to eliminate the question of speed, and the award solely to be one of merit and reliability. The run is to be over a distance of some 150 to 200 miles only. The trial being similar to that to be held in the Bombay Presidency, the date is to be fixed as soon after this event as possible—say the middle of January. The objects are to bring prominently before the Indian public the fact that motor-cars have been brought to such a stage of perfection that they are eminently suitable for use in India, more especially for district work; to induce tourists visiting the country to take their cars with them, and thus avail themselves of the good roads and perfect weather which are invariably assured to the traveller between the months of October and March; to call the attention of manufacturers in Europe and elsewhere to the wants of India in the matter of motor-cars. Any sort of car will be allowed to compete, and the most successful car will be that obtaining the largest total number of marks for the different points stipulated for. It is requested that all owners of cars will write as soon as possible to Mr. J. H. Rolfe, whose address we shall be pleased to give to those interested intimating their willingness to enter their cars. The entries will close on December 1st.

◆ ◆ ◆

Fees for Instruction.

OUR attention has recently been called to the high fees charged by some of the motor-car schools for instruction in the practical work of automobilism. There is no doubt that in such an industry as that connected with the motor-car time has not yet succeeded in fixing a standard, either of qualifications for teachers or of financial arrangements for the same. If those who claim to give instruction in motor-car driving are wise, they will, however, recognise that anything in the way of exorbitant fees at the outset is likely to prevent the ultimate success of any scheme of instruction which they may devise. In this as in everything else, the provision of well-equipped shops is a great expense, and that, of course, has to be borne in mind by those who intend to take instruction in a practical way. Such plants cannot be placed at the disposal of novices entirely for nothing, and after all, there should be a certain amount of give and take with regard to the monetary aspect of motor-car instruction.

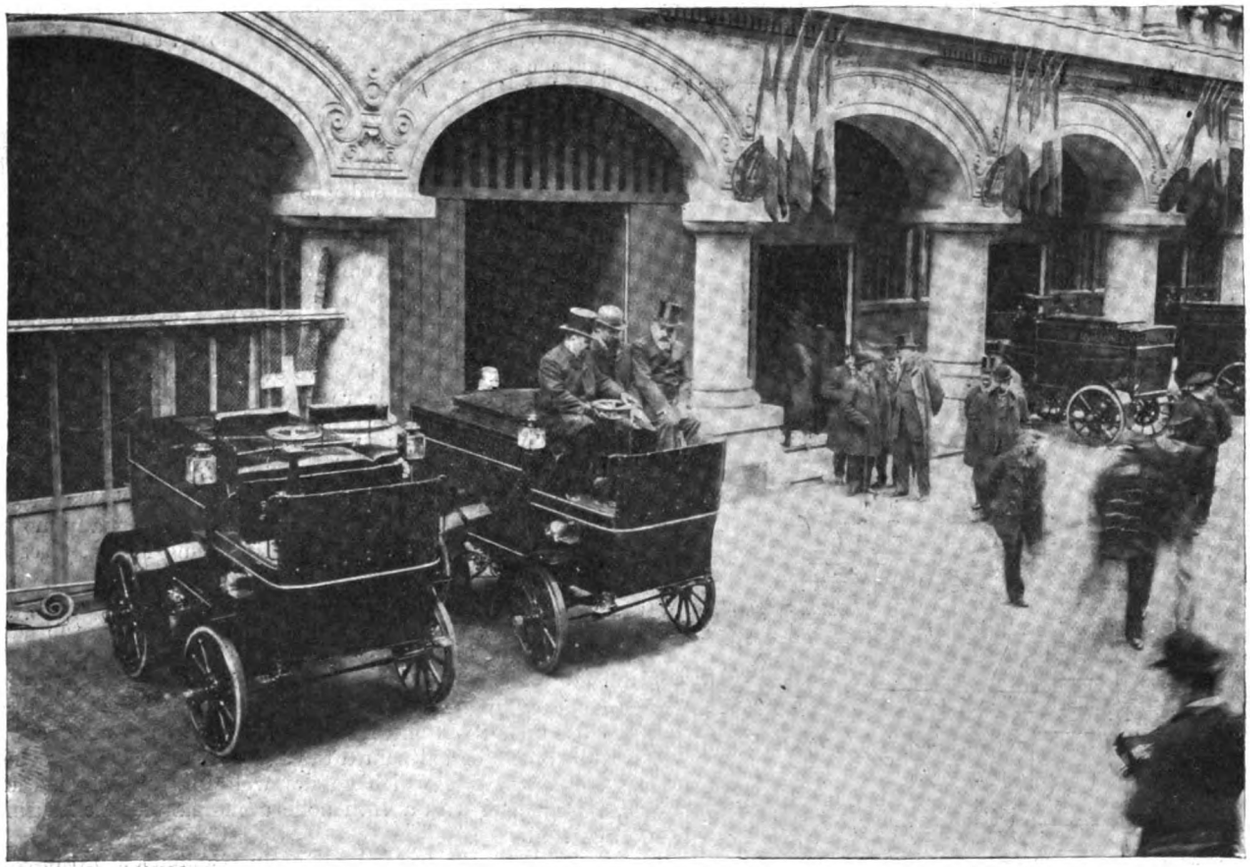
The Auto-Cycle Club Tri-car Trials. The Scene at the Starting Point at Hatfield. (*See page* 760.)

◆ ◆ ◆

The Gordon Bennett Race.

PROPOSITIONS for the alteration of the rules governing the Gordon Bennett Race had to be sent in by the 10th inst. to the French Club, and will be laid before the International Conference of Automobile Clubs in Paris on or about the 10th December. The following are the recommendations of the A.C.G.B.I.:—(1) That all the resolutions previously passed be cancelled. (2) That the Cup course should be extended from 500 kms. to 1,000 kms., since the former distance does not any longer, in view of the progress attained in the construction of motor cars, afford a satisfactory criterion. The cup would then be contested on two consecutive days, over a distance of 500 kms. on either day. (3) That we do not support the principle of altering the Gordon Bennett race into a team race, as it would destroy the personal sporting character of the event, and, moreover, the Montagu Trophy already provides for a team race under Gordon Bennett conditions. (4) That the competitors should no longer be allowed an unlimited number of pneumatic tyres, but a fixed number of tyres and inner tubes, stamped and registered. (5) That the weight limit for 1906 be reduced to 800 kgs.

Digitized by Google



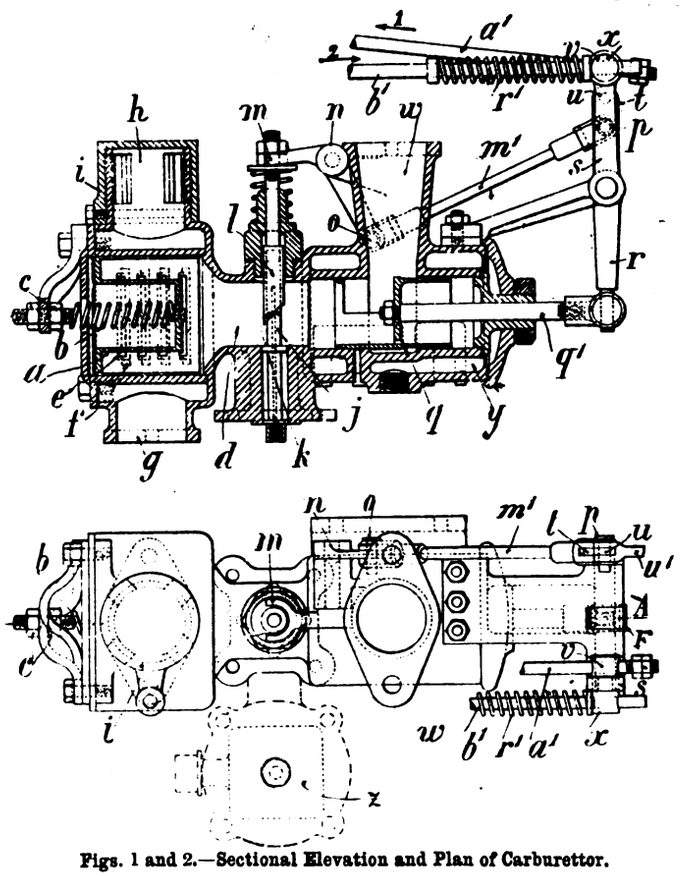
SOME HINTS ON NIGHT DRIVING.

POWERFUL headlights do not make fast night driving safe—they simply make it possible. The exercise of common sense is still necessary in these days of powerful acetylene lamps for automobiles. On these statements most motorists are agreed—theoretically. When it comes to their practical application, however, many forget. Given a combination of skill in driving, presence of mind in emergencies, and acetylene lamps, good time can be made on the road at night, but the risk caused by the unexpected remains. This produces far more mental strain and bodily fatigue in driving a given distance at night than would result in covering the same ground in daylight. Under any circumstances fast driving at night should not be attempted unless the car is equipped with powerful acetylene lamps, which are in perfect working order, and, even with such an equipment of lights, fast driving should not be attempted unless one is very familiar with the route to be gone over. Many drivers do not fit their lamps properly to the car. To be really effective the lamps should be fixed on the brackets in such a position that when lit the beams of light from them will be practically horizontal when the car is on level ground.

As is very generally known, the light from acetylene lamps casts very dark shadows, a characteristic which this light shares with the ordinary electric arc lamp. For this reason a road which is only slightly rough in its surface will appear to be very much more so when viewed by the light from an acetylene lamp. When a driver gets accustomed to this illusion he is, remarks the "Automobile," likely to become careless and take it for granted that when a road appears very rough, under the beams of the lamps, it is in reality only slightly so. Thus when a stretch of bad road is encountered the driver is likely to make an error of judgment, to attribute the apparent roughness of the road to the peculiar effects of the light, and, under the assumption that the road is good, high speed may be maintained until the wheels strike a ridge or hole so forcibly as to bend an axle or break a spring.

In driving at night particular care should be taken in going round turns. A rear end collision with a preceding car is easily possible on a sharp turn, especially if the car ahead does not carry a rear light. A moment's reflection shows that when the car is rounding a curve the headlights will show on the road only for a very short distance ahead, depending entirely on the radius of the curve. It follows as a consequence that if a car or other vehicle is rounding a curve just in front it will not be seen until the following car is very close, so close indeed that it may be practically impossible to stop soon enough to prevent a bad smash up. On dry roads it is usually very easy to tell when catching up with another car or horse-drawn vehicle, as the dust raised by the vehicle ahead is easily discerned when the beams of the acetylene lamps fall upon it. It should be an invariable rule to slow down a car when running into dust, and at the same time keep a sharp lookout. In the night time objects do not come into view progressively, as it were, as in the day time. When approaching an object in daylight it first appears small and indistinct, and gradually increases in size as one gets closer. When driving at night, however, with the aid of gas lamps, objects appear to flash into sight suddenly—appearing to leap out of the darkness. The suddenness of this appearance is intensified as the speed of the car is increased.

When driving at night motorists should exercise consideration for other road users. Horses are easily frightened by the dazzling rays from acetylene lamps. Frequently a horse that is met refuses to go by, and the best thing to do under such circumstances is to stop the car and get out and station a person in front of each lamp, with the body close against the glass so as to cut off all the rays of light.



The new Electric Mail Vans in the Courtyard of the Paris General Post Office (*See* p. 757.) [*La France Automobile.*

THE NEW PEUGEOT AUTOMATIC CARBURETTOR.

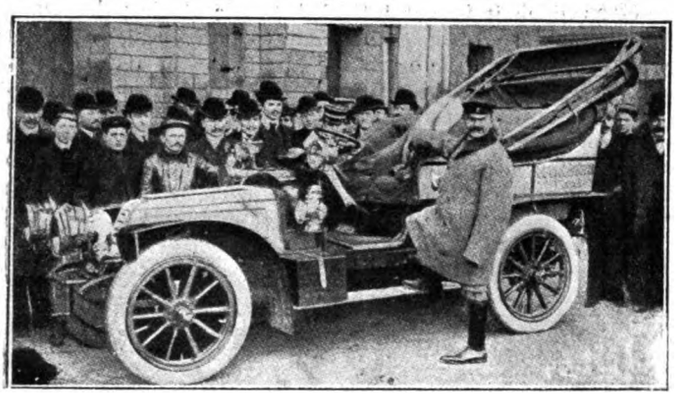
CALLING at Messrs. Friswell's extensive depot the other day we had an opportunity of inspecting a new automatic carburettor which is being fitted to the 1905 models of Peugeot four-cylinder cars. The device is quite a new departure in that provision is made not only for automatically regulating the amount of air in accordance with the speed of the engine, but the feed of petrol can also be increased by automatic means as the speed of the motor advances, in order to keep up the requisite proportions of air and vapour. Referring to the accompanying illustrations, Fig. 1 is a section and Fig. 2 a plan of the new carburettor. Two air inlets are provided, one at *g*, for the admission of warm air taken from around the exhaust pipe, and a second one at *i*, in which cold air can be admitted; the latter is provided with an adjustable opening, *h*, so that the amount of air allowed to pass through it can be regulated

Figs. 1 and 2.—Sectional Elevation and Plan of Carburettor.

by hand from the dashboard of the car. The total quantity of air which passes to the carburetting chamber, *d*, depends entirely on the suction of the engine, a series of holes, *e*, *f*, being normally closed by a plug, *a*, the holes being more or less opened as the suction overcomes the tension of the spring, *b*, provision being made for adjusting the latter by means of the nut, *c*. The petrol is fed, as usual, through a float chamber, *z*, to the spraying nozzle, *j*. It is here that the novel feature of the carburettor is found. The sprayer is arranged to furnish a variable automatic discharge of spirit and is provided with four small side holes, *k*, disposed in a horizontal row. The variable discharge of petrol through the sprayer is obtained by means of a cap, *l*, sliding closely on the cylindrical part of the sprayer. The cap, *l*, is provided with external connections in such a way that its position can be varied either by the automatic governor, by the accelerator pedal, or in conjunction with the throttle lever. One of the holes, smaller than the others, is always uncovered, so as to ensure the engine always getting a certain supply of fuel. The lower end of the cap is cut aslant in such a way that, as it rises, the other holes are successively uncovered. A balanced throttling piston, *q*, actuated automatically by the governor and also by the throttle lever regulates, according to the position of one or other of these parts, the quantity of carburetted gases which it is desired to admit to the cylinders, by the suction pipe, *w*. The piston, *q*, is actuated by a rod, q^1, passing outside the carburettor, and articulated on a lever, *r*, *s*, which is actuated by the governor rod, *u*, at the point *u*, by the accelerator rod, a^1, at the point *v*, and by the rod b^1 of the throttle lever at the point *x*. The operation of these regulating parts is as follows:—The hot and cold air are supplied in definite proportions to the carburetting chamber *d*, the carburetting liquid being sprayed into the chamber through one or more of the holes, *k*; the mixture thus formed is then sucked through the passage, *w*, to the explosion chamber of the engine, the quantity of such mixture being governed by the accelerator and throttle lever rods a^1 and b^1, which are moved in the directions of the arrows 1 and 2 and operate the piston *q* according to the quantity it is desired to admit to the explosion chamber. These rods a^1 and b^1 also act on the cap *l* through the rod m^1 and bell-crank lever m^2, by which means the mixture is made richer or poorer. Thus when the accelerator rod is moved the rod q^1 is drawn out and the size of the opening to the passage *w* increased, a greater number of holes, *k*, being also opened, allowing more petrol to flow, or when the throttle lever rod is moved the above operation is reversed. The governor rod, u^1, acts as an automatic retarder when the engine attains too high a speed, being controlled by the usual governor. In order to facilitate the working of the device in cold weather, a jacket, *y*, is provided to the mixing and throttle chamber, through which hot water drawn from the water-cooling system of the engine may be circulated. In designing the apparatus the Peugeot Company have in mind the provision of an automatic carburettor in which the proportions of air and petrol vapours of the explosive mixture may be adjusted in a very constant manner, irrespective of the speed or power required of the motor. It will be realised that such a carburettor will be able to secure the maximum of economy if the proportions obtained by the initial regulation of the mixture are such as to furnish the greatest calorific efficiency. We have seen the new carburettor in operation on a Peugeot four-cylinder car, and were much impressed with the rapidity of its action, any movement of the throttle lever in either direction being instantly responded to by the engine.

THE L.B.G. sparking plug sent us early in the summer by Messrs. Lamb Bros. and Garnett has so far proved a marked success. The plug was put into use in the middle of July last on a single cylinder car, and although the vehicle has since been driven close upon 2,000 miles, it has never yet been removed. In fact, during the period named the ignition has not given the slighest trouble, a fact which speaks well for the combination of the L.B.G. plug with a Lithanode accumulator which furnishes the current.

AT a meeting of the Yachting Committee of the Automobile Club de France the following localities were discussed as suitable for the race for the British International Cup for motor-boats next year:—The Bassin d'Arcachon, the Golfe de Morbihan, the Rade de Brest, and the Rade de Cherbourg. The final choice will be made within a fortnight. The race will take place between the 25th July and the 8th August. The entrance fee for each motor-boat is £20, half of which is returnable if it actually starts. It was also decided that the Automobile Club of France will organise a motor-boat race on the 15th July next between Calais and London.



EDISON'S latest invention is a disc wheel for motor-cars. The disc is built up of sections of endogenous wood—palm wood for instance—secured together and mounted between the flanges of a suitable hub. An elastic cushion is interposed between the disc and the body of the hub, whereby the disc is free to move elastically with respect to the hub, so as to accommodate itself to the inequalities of the road surface. The elastic cushion is made in the form of a continuous ring of pure vulcanised Para rubber, which it is possible to use, since it is not subjected to wearing or abrading influences, but is merely displaced or distorted.

CONTINENTAL NOTES.

Electric Mail Vans for the Paris Postal Service.

The Paris postal authorities are now employing fifteen electric vans for the conveyance of letters from the branches to the central office, and from the latter to the railway stations. Six of the cars have pneumatic tyres and the rest are fitted with solid tyres. The weight of the vehicles is one and a half tons, and the carrying capacity is about 12 cwt. The vehicles were built by Messrs. Mildè and Co.; the necessary current is furnished by a battery of 44 Heinz accumulators, having a capacity of 150 ampere-

Cormier Leaving Paris for his long Tour on the new 15-h.p. De Dion Car.

hours, sufficient to run the vehicles a distance of twenty-five miles on one charge. The battery is located in a receptacle below the driver's seat, and is so arranged that it can be entirely withdrawn and a fully charged battery substituted within five minutes. The controller is adapted to give eight forward speeds, three reverse, and two electrical brakes. By means of a pedal, the electrical circuit can be broken, thus stopping the motor whenever necessary in thick traffic, this corresponding to the clutch pedal in petrol cars. The vehicles are intended for an average speed of 11¼ miles an hour, the maximum being 17½ miles.

◆ ◆ ◆

The Dust Nuisance in Switzerland.

The Geneva section of the Swiss Automobile Club has decided to undertake a series of experiments with regard to the suppression of the dust nuisance. Trials are to be made with a number of dust-laying preparations, and tests are to be inaugurated as to the effect of speed, different designs of tyres, and the forms of car bodies on the quantity of dust raised.

◆ ◆ ◆

Automobilism in Roumania.

Slow but steady progress is being made by the automobile movement in Roumania, which has now its Automobile Club, of which Prince Bibesco is president. A 120-kilometre race was recently held between Bucharest and Giurgiu, in which five cars competed. Before motorists are allowed to drive cars, they, as well as their vehicles, have to be examined by the Prefect of Police, and to assist him in the work the Roumanian Automobile Club has appointed a special committee of four of its members.

◆ ◆ ◆

A Co-operative Garage in Paris.

A movement is on foot to establish a co-operative motor garage in Paris. The idea is for a number of motorists to join together in establishing and running a garage for the storage and cleaning of their cars. Should the scheme prove successful, it is also proposed to eventually lay down a repairing plant.

◆ ◆ ◆

Motor Racing in Sweden.

As was mentioned in this column last week, it is proposed to hold an automobile week in Stockholm from the 4th to the 12th February next. The meeting will be on novel lines, as it is proposed to hold the races on the ice near the island of Djursholm, in a fjord about eight miles to the north of Stockholm. There are to be different classes for racing and touring cars, and it is hoped that some of the leading French and English motorists will be induced to take part in the meeting.

◆ ◆ ◆

Austria and the International Motor-Bicycle Race.

Austria means to make a strong bid to win the 1905 international motor-bicycle cup race, the Motor-Cycle Section of the Austrian Automobile Club having already sent out circulars to the leading motor-cycle builders asking if they intend to enter for next year's event. If necessary, an eliminating trial will be held over a distance equal to that of the course of the cup race itself, in order to select the three best machines and riders.

◆ ◆ ◆

Motor Boats in Germany.

The German Automobile Club, which has been closely watching the development of the motor-boat movement, is preparing to include a number of competitions in its 1905 programme. Races are to be held during the season at Hamburg and at Kiel, while it is proposed to organise a race in the open sea, from Kiel to Copenhagen.

◆ ◆ ◆

A Motor-Boat for the Russian Navy.

Messrs. Pitre and Co., of Maisons Laffitte, have just completed a 40-h.p. motor-boat for the Russian Navy. The vessel is 32 ft. 9 in. long by 6 ft. 6 in. beam, the motive power being supplied by a 40-h.p. Fitz petrol engine. The boat weighs complete about 2,300 kilogs., and can, it is claimed, attain a speed of fourteen knots.

◆ ◆ ◆

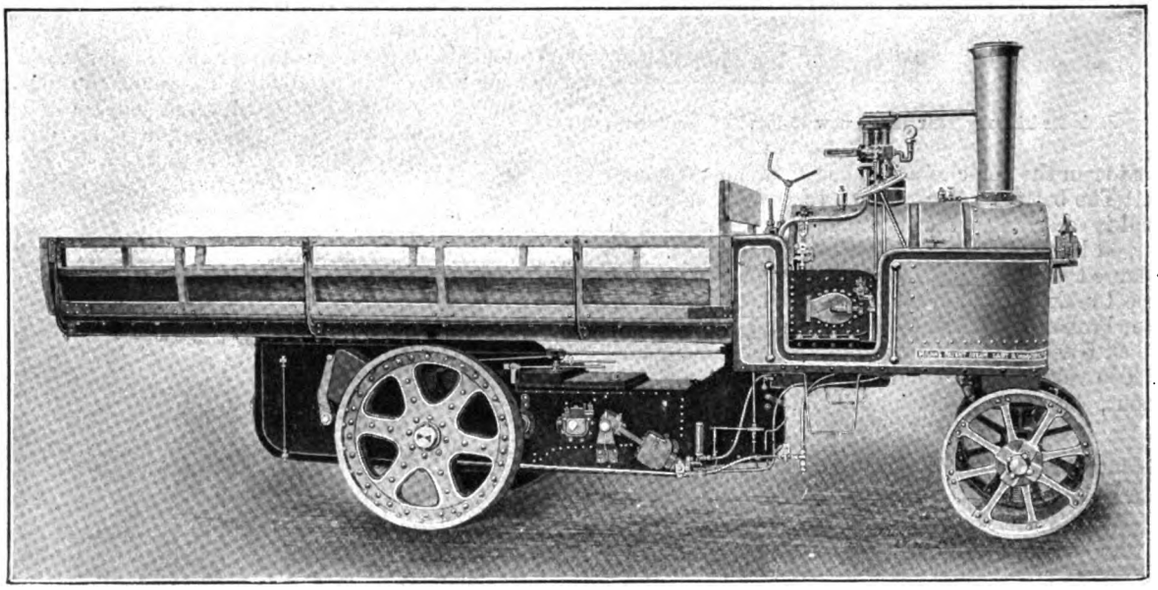
Public Services in Switzerland.

A company has been formed at St. Blasier, to inaugurate a public service of motor-cars between that town and Titisee for the conveyance of both passengers and goods.

◆ ◆ ◆

The Gordon Bennett Cup Race.

The question as to the course on which the 1905 Gordon Bennett Cup race shall be held has still to be decided. In



Palser on the new Serpollet Steam Car at the Gaillon Hill Climb.

addition to the proposed course in the Aix-les-Bains and Vichy districts, it is now suggested that an excellent one can be found in the Aveyron district, between Villefranche, Rioupeyroux, Pont-de-Salais, Millau, Severac-le-Chateau, and Rodez. It is announced that Mr. Gordon Bennett is presenting a large silver "plaquette" to the automobile clubs which have held the Gordon Bennett cup. The plaquettes, which are given as a permanent reward, will bear a silver reproduction of the cup with a suitable inscription.

MANN'S NEW STEAM WAGON.

THE accompanying illustration shows a new type of steam wagon which is being put upon the market by Mann's Patent Steam Cart and Wagon Company, Limited, of Pepper Road Works, Hunslet, Leeds, to meet the views of the large number of users who attach considerable importance to the general appearance of a wagon. At the same time all the essential features of the original Mann wagon have been retained and have not been sacrificed in the attempt to meet users' wishes or the prejudices of the general public. The design, in addition to the essential features of their present standard type of wagon, contains many new details based upon past experience. The new wagon has less of the traction engine appearance than the older designs, as, although the locomotive boiler is retained, it is hidden by neat coke bunkers round the front. The engine has been sunk between the side plates of the main frame to be out of sight, and also to leave sufficient head room to enable it to be inspected with ease, even when the wagon is loaded. It also allows of the use of one single open-topped oil-bath to take both engine and quick running gear with change speed clutches, so that the whole of the motion work can be got at as easily as with an open type engine by simply removing the top cover. The compound engine is reversed by a single

General View of Mann's New Steam Wagon.

eccentric gear of the bell-crank type, of which all the details are forgings and case hardened instead of castings. The reversing lever, regulator and steering wheel are all brought close together on the foot plate so that the wagon can be handled and managed by one man. The steering gear is so designed that without alteration to standard parts it can be placed at either side. The power transmission is of the spur wheel type with a bevel pinion differential gear. The spring gear is of simple form, the weight being taken on plate springs and the driving thrust taken by cast steel brackets in which the main axle boxes slide. The shaft centres are so arranged that the full amount of play is obtained without causing the gear to run untruly. The road wheels are of steel throughout, and the tyres put on in sections to allow of easy replacement and to give a better grip of the road for driving than can be obtained with a shrunk ring. The front wheels are carried on a pivoted front axle turned direct from the steering wheel by a worm and quadrant gear. This gives complete control, as it is self-locking, and, owing to the few joints, it does not become difficult to manœuvre when suffering from wear. The wagon illustrated shows an open-sided lorry, but they are built with any class of body desired to suit different trades. They can be had with steel or wood wheels and with or without tipping gear, in sizes to carry 3, 5 and 7 tons.

SOME USEFUL NOTES.

IT should be remembered that exhaust gases contain ingredients of a highly poisonous nature. Therefore, when the engine is run whilst in the stable, always have a door or window wide open so as to ensure free ventilation.

THE entire wiring of a car should be carefully examined from time to time for signs of wear in the insulation. At certain places the wires are exposed to continual, if slight, friction, which will ultimately break through the insulation and establish a short circuit. The timely application of a little insulating tape will often save much trouble in this respect.

CARS which it is not intended to use during the winter months should be given a thorough cleaning before they are stored away, and all the bright steel parts should receive a coating of vaseline, to prevent rusting. The grease may be cleaned off again in the spring with paraffin. When the cars are thus prepared they may be stored in almost any building where they are protected from the weather, although a perfectly dry room is preferable. In any case, previous to storing the vehicle away, the tyres should be taken off, done up in sacking and stored in a dry, dark place, especially if the machine is to be out of commission during the entire cold season.

IT is not always convenient to heat the motor stable. A open fire is not to be recommended, and some users of steam cars who let the pilot light burn under their machines during cold nights have had cause to regret it. The problem is easiest of solution where steam heat is used in the building. It would be interesting if some of our readers who keep their vehicles on their own premises would let us know what provision they make for heating their stables during the cold season.

WHEN a car has to be driven through the rain, a great deal of subsequent work and worry can be avoided if all bright parts are given a coat of vaseline. With such a coating there is no immediate necessity for wiping down and polishing such bright parts, as the grease prevents the rain from spotting and tarnishing, while it may be readily removed at any time. Should any plated parts become tarnished they may be restored to their previous brightness by the use of silver polishing powder and a little liquid ammonia.

THE novice is usually as guilty of sins of omission as he is of those of commission. He forgets to fill up a petrol tank before starting, and comes to a standstill five miles from anywhere. Perhaps the most usual piece of negligence is failure to lubricate either properly or promptly. These and other bits of

Digitized by Google

carelessness result in great inconvenience, and in certain damage to the car of a kind not to be classed with punctured tyres, worn cogs, clogged carburettors, and other purely accidental and unpreventable troubles. The owner of a motor-car, therefore, should early in his career acquire the habit of devoting a few minutes to the inspection of his vehicle every day it is in use, and hold that inspection before he starts rather than afterwards when out on the road, where, for reasons that he does not immediately suspect, he is obliged to interrupt his trip and often mix perspiration with profanity.

◆ ◆ ◆

One blunder which inexperienced motorists frequently make, and which occasions them no little chagrin, is attempting to start the car with one or more of the brakes on, so stopping the engine. Another consists in advancing the ignition lever too rapidly upon an engine which is slowed down under load. Changes of spark position should be gradual, giving the motor time to accommodate itself to the new conditions and sparing the moving parts the stresses to which they are otherwise subjected.

◆ ◆ ◆

It is well to occasionally examine the couplings and fittings on the oil and grease pipes on one's car, to see that there is no escape which would rob any bearings of their due and so cause overheating. A leak in a pipe of a multiple lubricating system is much more serious than a leak in a separate cup system, because it allows the reserve supply of lubricant to flow out and thus prevents sufficient pressure being applied to force the oil to the other bearings, which suffer in consequence.

◆ ◆ ◆

In making repairs to petrol-motors the greatest care is necessary, in reassembling the parts, to see that everything is put back in the correct position and that all adjustments are made exactly right. Particular care must be used with the ignition mechanism when making any changes affecting the timing. In such cases, before it is attempted to start the motor, it should always first be ascertained that the spark occurs at the proper moment. As is well known to all motorists, when the spark occurs too early a back fire is produced in the engine; and if the spark occurs exceptionally early, bodily injury may result to the person attempting to start the motor.

◆ ◆ ◆

Some gear-boxes are made in which the wheels that move (the sliding sleeve) are the larger ones, that is, the driven shaft and not the driving or clutch shaft; with this type of gear difficulty may be experienced in coming back from third speed to second, and second to first, but it may be easily overcome in the following way:—Depress the clutch at the change, and as soon as the wheels touch, let the clutch in, at the same time pulling the speed lever into position. The change will then be effected without any difficulty.

◆ ◆ ◆

If the starting handle on one's car is of the detachable kind it is always well to make sure that it is on board when starting out for a run, and furthermore that it is so safely secured that it may not be lost *en route*. With no handle available many a motorist has been puzzled to know what to do. There are, however, one or two ways of starting an engine without a handle. One consists of rolling a cord round the flywheel or round the clutch, then pulling hard enough to overcome the compression of the motor. This method is not easily applied to every motor, and unless performed with considerable dexterity presents some danger, for the cord may get entangled in the moving shafts if it is not withdrawn with extreme rapidity. A simpler means is to set the transmission on the high gear, switch on the ignition, and, letting in the clutch, get someone to push the car, withdrawing the clutch as soon as an explosion occurs. To start the motor in this way it is necessary to use the high gear, because the low gears would drive the motor much too fast, besides requiring an effort of strength to push the car beyond the help usually obtainable. Naturally, if the car can be started on a slightly downhill road the work will be the easier.

THE ADAMS MOTOR-JACK.

A novel and useful form of jack, for raising motor-cars off the ground, has been recently devised by Mr. Henry Adams, of Tunbridge Wells. It is designed to bodily lift either the front or back part of a car, by tilting jack towards the vehicle, and placing the claw under the axle. By simple leverage with the handle the car can then be raised from the floor about

Fig. 1.—The Adams Jack.

two inches, and the jack being on wheels it enables one person to move the car in any position desired, either backwards or forwards, placed in the shortest lock possible, and turned round in a space its own length. The car is then manipulated exactly as an ordinary bath chair, and by allowing the leg under the handle to rest upon the floor, the car is placed in a firm position resting on the jack, ready for repairs, cleaning or removing tyres. The operation is done by one person only in a standing position in much less time than by an ordinary lifting jack. The jack is made in two patterns; one is a lever jack only, and made with a telescopic centre shaft which can be set to any height from 12 in. to 18 in.; it weighs 48 lbs. and will lift cars up to 20 cwt. The second pattern is made with a screw in addition to the telescopic shaft; it stands ten inches from the floor when down, and will pick up a car by the axle by tilting the jack

Fig. 2.—The Jack in use.

forward towards the car. When the claw on the top of the jack reaches the axle, the handle is pulled towards the operator, levering the car on to the jack, when it can be raised further if necessary by turning the cross-bar handle. By means of the screw and telescopic shaft the jack can be extended to a height of twenty inches; this pattern weighs 58 lbs. and will lift up to 30 cwt. The jacks can be obtained from Messrs. Gamage.

MOTOR CYCLING NEWS.

THE Auto-Cycle Club's 100-mile trial for tri-cars was held on Saturday last, the course extending from Hatfield to Newmarket and back. Of the fourteen competitors who had entered for the event, ten put in an appearance at the starting-point, these being J. F. Crundall, 3½-h.p Humber; W. J. Milligan, 4½-h.p. Bradbury; J. Browning, 4½-h.p. Riley; W. King, 4½-h.p. King; W. Batchelor, 3½-h.p. Wallace; W. H. Watson, 3½-h.p. Greyhound; G. Henshaw, 4½-h.p. Avonmobile; Eustace Gray, 3½-h.p. Humber; T. Sopwith, 6½-h.p. Pearson; and the Hon. H. Bruce, 4-h.p. Ormonde. So far as the non-stop character was concerned, the event was a disappointment, as not a single competitor got through without a stop. The first to retire was Watson, the gear of whose machine jammed. Browning dropped out owing to clutch troubles on his Riley eight miles from the start. Milligan (Bradbury) experienced ignition troubles, and Gray (Humber) broke an inlet valve stem. On Wades Mill Hill the machines were timed over a course measuring one-third of a mile. Crundall (Humber) made the best time (1 min. 19 2-5 sec.). On the return journey the machines were pulled up twice in order to test the brakes. The first to reach Hatfield was Sopwith, who had left last but one. He had covered

Hill Climbing in Japan.

the distance in 5 hr. 1 min., thus averaging a speed of twenty miles an hour. The order of arrival of the others was:—Crundall, Batchelor, Henshaw, King, and the Hon. H. Bruce.

◆ ◆ ◆

IN connection with the foregoing reliability trial for passenger cycles, it is of interest to note that, of the ten who started, six finished within the maximum time, and of these a majority approached to the minimum time, which corresponds to twenty miles per hour. The weather throughout the day was fine, and the roads generally in good condition. The judges have recommended the committee of the Club to award a silver medal and certificate for excellence in—(1) Fuel economy, (2) hill climbing, (3) ease of starting and control, (4) brakes, to vehicle No. 12, 6½-h.p. Pearson, entered by Mr. T. Sopwith; vehicle No. 10, 4½-h.p. Avon Trimobile, entered by Avon Motor Manufacturing Co.; vehicle No. 8, 3½-h.p. Wallace, entered by Mr. Wallace Batchelor; vehicle No. 7, 4½-h.p. King, entered by Messrs. W. King and Co.

◆ ◆ ◆

IT appeared in the trial that drivers had not sufficiently studied the regulations, and many might have gained specific advantages or avoided loss of credit by doing so. The brake test and the stop and start tests showed that the drivers were not as skilful in handling their machines as might have been expected; for instance, one or two men momentarily grasped the wrong handle or threw the lever in too late, unclutched too late, or only used one brake in the emergency stop. There were no stoppages on account of tyre troubles, though provision had been made in the regulations whereby a machine would not be thereby disqualified. The tests seem to show that the brakes were not always designed to be equally efficient forward and backward. Brakes that are easily thrown into and out of action unquestionably facilitate restarting on a hill, and the fact had been overlooked in at least one case.

◆ ◆ ◆

WITH regard to transmission the judges observe the manner in which water-cooling enables an engine of given cubic capacity, not only to somewhat increase its power, but also to maintain the increased power for long periods, must be borne in mind when designing the transmission. For heavy vehicles, such as tri-cars, the use of belts could probably be retained, if their proper proportioning were more carefully studied. A large and convenient water inlet, so placed that any liquid which splashes over shall not impair the insulation of the sparking plug or wires, might be more generally provided. Equal attention should be paid to the petrol inlet, providing it with an internal and detachable filter. Three instances of choked petrol pipes occurred in the trials.

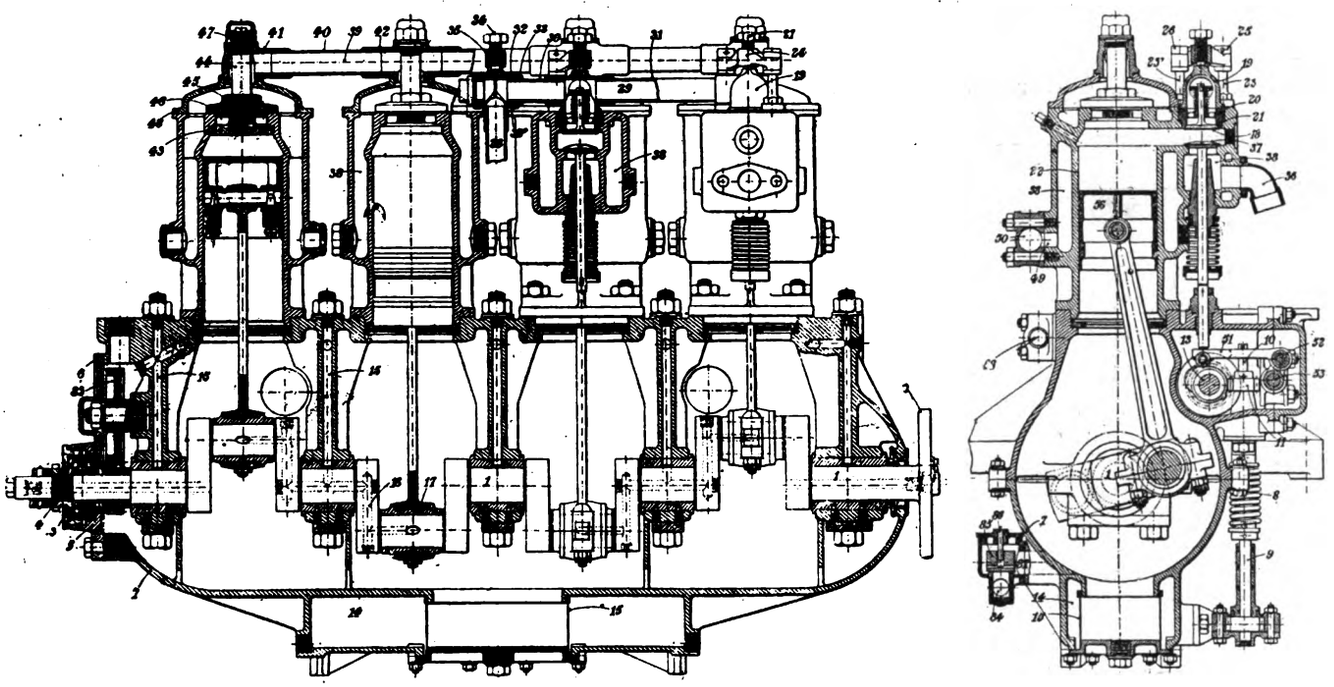
◆ ◆ ◆

IN the evolution of the change gear tri-car from the single-geared machine, the proper distribution of weight necessary for the greater road adhesion of the driving wheel when the low gear is in use has in some cases been overlooked. On certain machines the driving wheels skidded considerably when re-starting on an average gradient. It is as well to remember that this skidding is not only severe on the single tyre, but wastes the engine power as much as belt slip.

◆ ◆ ◆

THE adoption of change-speed gears has naturally led to the use of water-cooling, with the attendant difficulty of combining lightness and strength. The strains to tank and pipe work on a partially-sprung machine are more severe than in the case of cars, and as the materials give little scope for improvements, attention should be centred on producing a stronger and simpler design. It is to be noted that by far the largest number of troubles arose in connection with the water systems. The possibility of dispensing with the pump by using simple and direct water connections, and placing a more efficient radiator high above the engine, seems to merit further careful trial. Thoroughly efficient radiators, with sufficient surface to prevent boiling on long hills, would obviate the necessity for tanks with their load of water, fragile joints and troublesome attachments.

◆ ◆ ◆



THE winter cycle racing track in Paris was opened for the season on Sunday last, the races being unfortunately attended by a nasty accident to Lanfranchi, whose recent record-breaking rides on his Peugeot machine have made his name a familiar one in the motor-cycling world. There were four competitors in the 10-kilometre motor-bicycle race—Fossier, Danglard, Anzani, and Lanfranchi; all were travelling at a high speed when the latter's machine skidded, pitching the rider against the fence and knocking him unconscious. Anzani, who was close behind, failed to clear Lanfranchi's machine, and he also was brought to the ground, but fortunately escaped serious injury. Lanfranchi, on the other hand, had to be taken to the hospital, where it was found that, in addition to other injuries, he had broken his leg. The accident naturally put an end to the day's racing.

◆ ◆ ◆

FOR the 1905 season the F.N. Co., for whom Messrs. McTaggart (Limited) are sole agents for the United Kingdom, are bringing out a four-cylinder motor-bicycle. The cylinders are placed one behind the other, and are air-cooled. Automatic inlet valves are employed. One of the chief novelties is the adoption of the bevel-gear system of transmission between the crank shaft and the rear road wheel. A new type of carburettor with automatic supplementary air inlet valve and a new arrangement for distributing lubricating oil evenly to each of the four cylinders are also prominent features of the new machine.

Digitized by Google

The De Dion 15-h.p. Four-Cylinder Motor.

Figs. 1 and 2.—Sectional Elevations of Motor.

AS has already been announced, Messrs. De Dion-Bouton are bringing out a four-cylinder car for the 1905 season. Hitherto their productions have been confined to engines having at most two cylinders, but in the meantime experiments have been in hand, the results of which are seen in the new four cylinder motor of which we are now able to publish a description, together with sectional drawings. As leading characteristics, the new motor (Figs. 1 and 2) has four separate cylinders, automatic inlet valves, a released compression starting gear, oil lubrication under constant pressure, and ignition by single trembler contact-maker conjugated to a secondary current distributor. The four-throw crank shaft is supported on five bearings, there being one between each cylinder, in addition to the two end ones. The cylinders are fired in the order 1, 3, 4, 2, counting from the forward end. To overcome the bad effect of longitudinal thrusts on the shaft a ball race, 3 (Fig. 1), forming a support, is fitted on the starting handle side. Rods extending from the top of the upper half of the crank case of the motor form the supports of the bearings of the crank shaft; the power generated by the explosion is, therefore, transmitted from the cylinder to the upper crank case through the pistons, connecting rods, and crank shaft alone, without over-straining the joints of the half-crank cases, as would happen if the bearings were held together by the joint itself. The big ends of the connecting rods and the bearings can thus be easily inspected or adjusted, owing to the readiness with which the bottom half of the crank case can be detached. Each cylinder, together with its water jacket, is cast separately. The bottom of the cylinder, 43, alone is jointed, but the water joint is independent of the combustion chamber joint. The pistons are of steel, and are fitted with four piston rings.

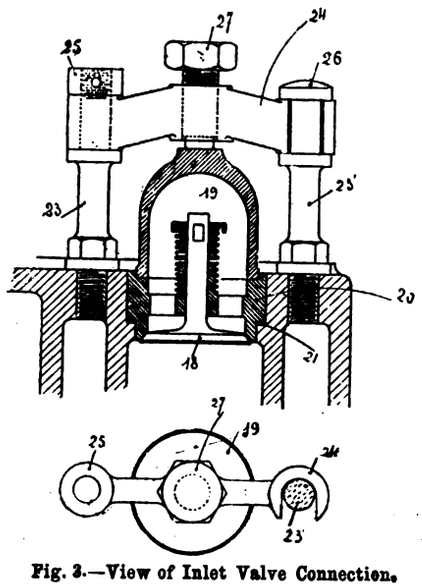


Fig. 3.—View of Inlet Valve Connection.

The lubrication of the different bearings is assured by a geared pump, actuated by means of a spring, 8, Fig. 2, uniting the spindle, 9, of one of the pump pinions to a vertical spindle, 10, carrying a pinion, 11, meshing with a worm wheel, 12, fixed on the cam shaft, 13. The oil drawn up from the reservoir, 14, formed in the bottom of the crank chamber is drawn in through a filtering gauze, 15, and is sent by the pump to the upper part of the crank chamber in a longitudinal conduit, 88, which diverts it to the different bearings by channels such as that shown at 15. Channels, 16, formed in the interior of the crank shaft and cranks receive the oil from the circular grooves in the bearings and conduct it to the heads of the connecting rods. In order to ensure a constant lubrication under pressure, whether the oil is limpid or viscous, a kind of relief valve is placed on the channel, 84, which it traverses in coming from the pump. When the pressure becomes too great, the valve, 85, is raised and the oil returns to the crank chamber by the orifice, 87.

The mixture from the carburettor is conveyed by a tube, 28, into a horizontal conduit, 29, running the whole length of the motor. This conduit is in two symmetrical parts, forming a single detachable piece for each pair of cylinders. The admission of the gases is effected by suction valves, 18, in the ordinary manner; the method of fixing the valves, however, presents certain peculiarities. Each valve is surmounted by a small dome, 19, Fig. 3, the base of which engages in a circular recess in the seat, 20, of the valve, lodged itself with the interposition of a joint, 21, in a special cavity. To maintain the dome, 19, two little columns, 23, are fitted for each valve, these being screwed into the cylinder casting. On their upper part these columns are joined by a cross-piece, 24, having at one end an eye threaded on

Digitized by Google

one of the columns and maintained by a pinned nut, 25, whilst the other end has the form of a fork engaging round the small column, 23, under a head, 26, of the latter. One can easily see that to fix the dome, 19, it is sufficient after having engaged it in the lodgment of the seat, 20, to make the cross-piece, 24, turn horizontally around the column, 23, until the fork at the other end embraces the column, 23, it is sufficient then to tighten the central screw in the cross-piece. To withdraw a valve it is only necessary to loosen this central screw one or two turns, and turning round the cross-piece, 24. The exhaust elbows, 36 (Fig. 2), are united in a collector, not shown, which conducts the burnt gases to the silencer. Each exhaust valve, 37, is actuated in the ordinary way

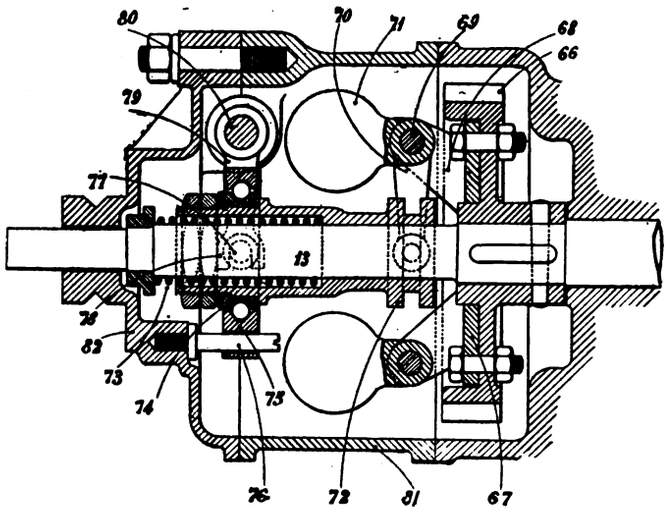

Fig. 4.—Sectional View of Governor.

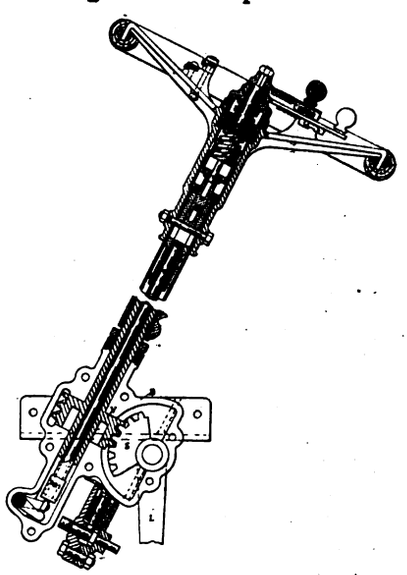

by the raising of a lever, 5, of which the head rests on a cam fixed on the shaft, 13, of the motor. The joint of each lever is movable, and for this purpose each lever is fixed on a small spindle, itself joined to an auxiliary longitudinal shaft, 53, by two small cranks. The result is that the angular displacement of the shaft, 53, whether by hand or by the effect of the governor, produces a variation in the raising of the exhaust valves, thus permitting within certain limits the regulating of the speed of the motor. The shaft, 53, has another function; by longitudinal displacement it allows the working of the compression release mechanism. The same profile is not given to the cams, 55, over their whole width; during the normal working of the motor one part only of the width of the cam comes above the head of the lever, 51, and consequently the exhaust valve is lifted to the extent determined by the profile of this part of the cam. If the shaft, 53, is displaced longitudinally the lever heads can be brought to rest on a part of the cams of different profile from the normal, and so alter the lift of the valve as to bring about the compression release necessary for the starting of the motor. The longitudinal displacement of the shaft is obtained in a simple way: a coil spring resting at one end on the small case enclosing the shaft, and at the other end on a pinned bush, pushes the shaft back normally towards the right. When it is desired to make use of the compression release mechanism a small shaft having a finger engaged in the groove of a bush fixed on the shaft is made to revolve, this movement bringing the requisite part of the cams under the exhaust-valve lever heads, 51.

The governor shown in section in Fig. 4 is mounted on one end of the cam shaft, 13. The half-speed pinion, 66, is joined by means of bolts to a plate, 67, carrying eight ears, 68, joined in pairs by a small spindle, 69, on which four levers, 70, each one carrying one ball of the governor, are fixed. Each lever, 70, ends in a nipple engaged in the groove of a collar, 72, sliding on the end of shaft, 13. A coil spring, 73, tends to push back the collar, 72, in the direction which brings the balls, 72, towards the shaft, 13. One of the halves, 74, of a ball race is borne by the collar, 72, whilst the other part, 75, which a gudgeon pin, 76, fixed to the case, prevents from turning by engaging in a notch, has two nipples diametrically opposed, 77, each engaged in a fork, 78, fixed at the end of a lever, 79, oscillating round a spindle, 80. When the motor is working the balls, 71, move away from the shaft, 13, the spring, 73, is compressed, and the shaft, 80, oscillates, the movements of this shaft acting on the throttle valve. The water enters the cylinders by openings, 49, branched on a collector, 50, running the length of the motor, and escapes by a conduit, 39.

(To be concluded.)

THE C.G V. STEERING GEAR.

THE accompanying illustration shows a section of the steering gear used on the C.G.V. cars, the British agents for which are the London Motor Garage Company. As will be seen, the gear is of the worm and sector type, the hand wheel operating the worm V, which is keyed at its upper end to the steering post or column. A toothed bronze sector S is keyed to a shaft which carries the lever arm L, from which a connecting rod runs to the steering knuckles. This lever arm L is provided at its lower end with a spherical knob, which fits into a spring-cushioned socket. A bronze casting B incloses the worm and sector, and this case is filled with grease previous to being definitely secured to the vehicle frame. All dust is excluded and the gear is therefore protected against rapid wear. The worm V has a quadruple thread and gives a normal steering reduction. The manufacturers have not considered it advisable to mount the gear on ball thrusts employing plain friction surfaces of large dimensions. Inside the upper part of the steering column is arranged quite a collection of worms and nuts for operating the throttle and the ignition. The spark lever is connected to the

central rod, while the throttle lever controls at tube surrounding this rod. A central hole through the worm shaft permits the passage of the rod and tube, which, at the bottom of the case B, action their respective levers, thus enabling the driver to control the ignition and the admission of gas by means of two levers working on sectors on the steering wheel. The inclination of the steering column with respect to a horizontal plane is 64 degrees.

A MOTOR-'BUS service between Ipswich and Woodbridge is being suggested by some residents of the latter place.

PRINCE HENRY OF PRUSSIA recently paid a visit of inspection to the works of Messrs. Benz and Co, at Mannheim, and left behind him an order for one of the latest 40-h.p. Benz-Parsifal cars.

THE Dunlop Pneumatic Tyre Company (S.A.), Limited, of Capetown and Johannesburg, have been appointed South African agents for the "Polkey" lamps, including the patent public service headlight, reflector headlights, and motor-cycle lamps.

HERE AND THERE.

THE present strength of the Motor Volunteer Corps is 155.

THE Kent Automobile Club will hold a run to Brighton on the 3rd prox.

LORD AND LADY DUDLEY intend shortly to make a motor tour through France.

THE Institute of Chauffeurs, Limited, has just been registered with a capital of £3,000.

A 14-18-h.p. Hallamshire car built by Messrs. Durham, Churchill, and Co. This type of car has done exceedingly well in all the events in which it has competed during the year, and won the gold medal in the £200 to £400 class at the recent Portmarnock Speed Trials.

MESSRS. PHILLIPS AND SON, of King's Road, Reading, have been appointed official repairers to the Automobile Club.

AMONG new members of the A.C.G.B.I. are the Earl of Wharncliffe, Sir N. J. Menzies, Bart., and the Hon. W. E. Guinness.

MR. G. P. RICE is developing the motor business at Paddock Wood, and in addition to providing garage facilities is now letting cars on hire.

ADDITIONAL premises have been taken by the United Motor Industries, Limited, at 45 and 46, Poland Street, W., which are now being used as stores and workshops.

AT the ploughing match of the North Kent Agricultural Association at Dartford last week, the Ivel Agricultural Motor was awarded the gold medal of the society.

THE Britannia Motor Garage, Limited, the formation of which was recently referred to in these columns, have now opened their premises at 110, High Street, Marylebone, W.

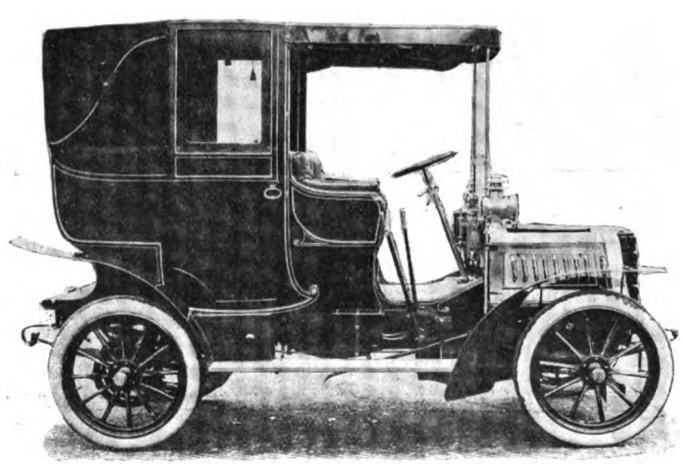
THE Yorkshire Automobile Club have been granted permission by the Filey Urban Council to hold speed trials early next year on the sands which extend southward from Filey Brigg.

MR. G. E. ROBERTS, the late secretary to the Motor-Cyling Club, will have charge of the Coventry depot of United Motor Industries, Limited, which was opened in Gosford Street on Monday.

RECENT Surrey and Sussex appointments of repairers to the A.C.G.B.I. include Mr. N. J. Wilmott, of Bognor; Mr. A. Humphrey, of Chichester; Messrs. Wood and Trussler, of Cranleigh; Mr. G. W. Rice, of Surbiton; and Messrs. P. J. Buddery and Company, of Wimbledon.

AN illustrated lecture on automobilism up-to-date will be delivered by Mr. E. Shrapnell Smith, Secretary and Treasurer of the Automobile Mutual Protection Association, at the Grand Hotel, Leicester, on Tuesday next, under the auspices of the Leicestershire Automobile Club.

A NEW motor-car service between Glasgow and Greenock has been inaugurated. The intention is to carry grain from the city and return with sugar, and this method, it is expected, will be less expensive than the present, which involves excessive handling in connection with the lightering of the articles between the two ports.



THE commandant of the Royal Military College, Woolwich, availed himself for the first time of the services of a member of the Motor Volunteer Corps last week, when Captain H. F. Trippel conveyed the commandant and three other officers from Woolwich to Dartford, when some highly important work in connection with a reconnaisance class was successfully carried through.

AS evidence in support of their petition to the Lancashire County Council to widen Crossford Bridge, the Stretford District Council recently obtained particulars of the traffic passing night and day over the bridge for the week. The following was the result:—Cycles (including motor-cycles) 9,207, motor cars 561, traps and other vehicles 4,038, lorries and carts 2,862; total 16,668.

WE have received notification from the publishers of Charles Letts's "Cyclist's Pocket Case" that the late Mr. W. H. Norton, of Anerley, who was killed by collision with a motor-car whilst cycling near Beckenham a few weeks ago, was in possession of one of the £100 insurance coupons issued in connection with this case. The case, which is of excellent value apart altogether from insurance policy contained therein, can be usefully carried by all cyclists and motor-cyclists.

MR. P. N. HASLUCK'S new volume on Metal Working just published by Messrs. Cassell and Company, Limited, extends to 800 pages and contains over 2,000 illustrations. The scope of the book embraces practically the whole art of working metals with hand tools and with such simple machine tools as the small engineering shop usually contains. The chapter concerned with the construction of a petrol motor will be of particular interest to many of our readers, especially as it is characterised by lucidity of statement and practical knowledge.

ACCORDING to the "New York Journal of Commerce," the liabilities of the American Automobile Association as regards claims for damages in connection with the recent Vanderbilt Cup race were covered by a policy written by Lloyds, London. The risk carried was understood only to apply in case of claims by spectators resulting from accidents and not to cover the participants in the race. Practically all the liability insurance companies in New York were offered the business, but declined, and the policy was finally effected with Lloyds by cable.

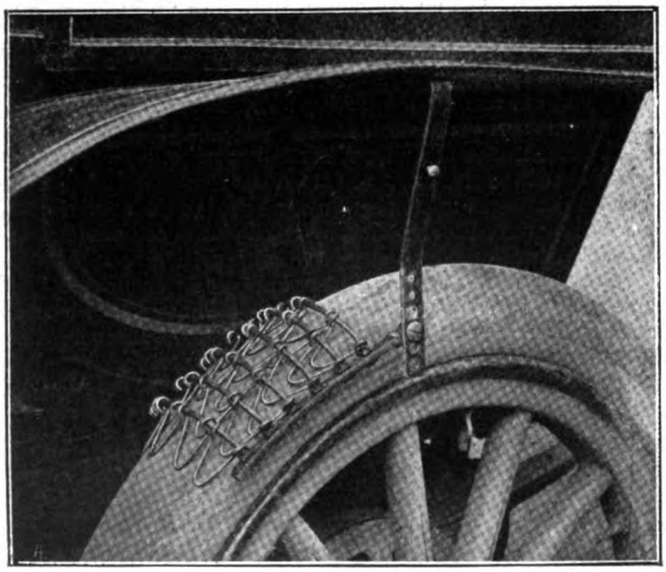
The new 9-h.p. Gladiator Landaulet. The car has heavy tyres nearly 4 inches in diameter to all four wheels, four speeds and a reverse, and self-regulating Carburettor.

A RECEPTION was given on the 11th ult. by the Automobile Club of America to the foreign motorists who visited the United States for the Vanderbilt Cup race. An address was given by the President, in which he recommended that at the race next year better facilities should be provided for keeping the spectators clear of the course at the start and finish. At a meeting of the club on the 18th ult., the topic for discussion was "Automobile Racing in Europe." The guests of the evening were M. Thery, the winner of the 1904 Gordon Bennett race, and M. G. Caillois, the winner of the Gaillon hill climb of 1902.

Digitized by Google

A GARAGE is being opened at Peterborough by Messrs. T. Woodman and Company.

THE Hockley Brook Garage has been established at Soho Hill, Birmingham, by Messrs. Fowler and Cashmore.



MESSRS. WALSH, NICHOLLS AND CO. are devoting a portion of their new works at Dudley Road, Wolverhampton, for garage purposes.

ON Saturday the London and South-Western Railway Co. were experimenting on the Farnham and Haslemere road with a 20-h.p. motor char-a-banc.

"HINTS on Handling a Turner-Miesse Steam Car" is the title of a *brochure* just published which will be of value to all users of that type of automobile.

IT is announced that the Italian Minister of Posts and Telegraphs has given out orders for a number of Fiat cars for use in connection with the postal service in Rome and other large towns.

To the many nail catchers which have already been described in the *Journal* has now to be added the "Challenge," which has lately been introduced by the Encore Cycle and Motor Company, Fore Street, Ipswich. The illustration herewith so clearly shows the device that but little description is necessary.

It will be seen that the nail catcher and puller is made up of a series of V-shaped wires held in a frame supported from two stays fixed to the underside of the mudguard. The puller can be readily adjusted as to height; it is claimed by the makers that a nail or flint cannot pass the pullers, as the latter, being V-shaped, act as a vice, and should the nail be missed by one, it is caught by another.

A CIRCULAR letter calling the attention of the superintendents of railways centreing in New York and district to the failure of engine drivers to sound the whistles or ring the bells of their locomotives when approaching level crossings, has just been sent out by the Automobile Club of America.

AT a meeting of a joint committee, representing various societies interested in untaxed alcohol for industrial purposes, the following gentlemen were nominated to offer evidence before the Departmental Committee appointed by the Chancellor of the Exchequer:—Mr. John C. Umney, Professor A. G. Green, Mr. David Howard, Mr. E. A. Webb, and Mr. Walter F. Reid.

MESSRS. FLEMING AND CO., of Rue Vicq d'Azir, Paris, have sent us a sample of a new preparation they have lately introduced under the name of "Pneu Cure," for filling up cuts and holes in the outer covers of motor pneumatic tyres. The fluid is easily applied, and, judging from the specimen section of a repaired tyre they have also sent, is an effective means of keeping one's outer covers in good condition.

THE Humber Company are, we learn, bringing out a new 8-10-h.p. four-cylinder car for the 1905 season.

ON Friday of next week the Earl of Anglesey's 18-h.p. Mors Pullman car will be offered for sale by auction at Anglesey Castle.

SPACE for the display of a petrol locomotive has just been taken for the Motor Car Exhibition at the Agricultural Hall, in March next.

AN echo of the Vanderbilt Cup race was heard in Paris on Saturday last, when Messrs. Panhard and Levassor gave a banquet in honour of Mr. Heath and his recent victory in the race on Long Island.

THE Hozier Engineering Co., Ltd., have recently taken possession of an extensive building, covering an area of 40,000 square feet, and now entirely devoted to the building of the bodies of the Argyll cars. There is ample accommodation for 300 men, and the company is in a position to turn out thirty finished bodies per week.

DURING the last nine months Messrs. A. Donaldson and Co. Limited, have had a new garage under construction in Westfield Avenue, Edinburgh. The premises cover half an acre, and include a large hall capable of accommodating 300 cars, as well as engineering, smiths', and coach-building workshops. The garage will be open night and day, and Messrs. Donaldson and Son will keep a full stock of petrol, oils, spare parts, etc.

A NOVELTY in the way of motor meets was the meet of motor-tricyclists held at Hill House, Mr. A. A. Padley's place at Market Rasen, a few days ago. There are still several of the De Dion type of motor-tricycle running in Lincolnshire. The idea was not taken up till a few days before the meet, but there was a good turn-out, though the weather was bad. Tea was taken at the White Hart, and Mr. Padley invited them to repeat the meet next year at a more seasonable time.

MESSRS. WEBSTER AND BENNETT, of Coventry, who are devoting much attention to the subject of machine tools for motor-car builders, have lately introduced a special machine designed to produce multiple cams solid with their shaft for motors. It is known as a horizontal motor cam-shaft profile milling machine, and is not only designed for profiling cams solid with the shaft, but separate loose cams can also be easily profiled by means of adjustable mandrels. Another new machine is a 30-in. boring and turning mill, which is rapidly taking the place of the lathe for the boring and facing of cylinders, crank-chambers, and such like work.

AN excellent hand-book on the care and management of the Wolseley vehicle has been issued by the makers of these automobiles. Most conveniently arranged and clearly illustrated, the work, which extends to nearly 150 pages, should prove indispensable to all who possess Wolseley cars, and of considerable value to those motorists who do not. After each chapter dealing with a special feature of the mechanism, a page is devoted to a "summary" consisting of hints which should prove extremely serviceable to the mechanician as well as to the owner. Having carefully perused the work, we can all the more thoroughly commend the Wolseley Company on the service they have rendered to automobilists in the publication of such a hand-book.

MR. C. G. WRIDGWAY, who has still many friends in this country, but who has been in the motor business in the United States for some years, met with a nasty accident at a track race meeting at Brighton Beach, near New York, on the 22nd ult. It took place at the end of the second heat of a five miles handicap race, in which he was driving a 24-h.p. Peerless, with temporary racing body. The competitors had completed the last lap, but were making another circuit of the track at speed, apparently uncertain whether they had finished, when, as he rounded the turn into the final straight, the seat of Mr. Wridgway's car came off and he was thrown out of the machine, falling on the track on his shoulder and the side of his head. The car cut diagonally across the track and plunged through the outer fence, coming to a stop against the inner wall of one of the sheds, the front wheels and the radiator being smashed up. As Mr. Wridgway passed the judges he stated he was not hurt, although blood on his face showed that he had received a nasty fall.

CORRESPONDENCE.

THE LUXURY OF APPEAL.

To the Editor of *The Motor-Car Journal.*

Sir,—About six months ago I was summoned at Hastings Police Court for furious driving. I was unable to get down there in time for the Court. On my way, however, I sent a telegram to the magistrates from Victoria Station informing them that I was *en route*. When I arrived at Hastings I discovered that despite my telegram I had been convicted in my absence and fined £10 and costs. On the advice of my solicitors I appealed against the conviction, with the result that the second hearing was fixed for the June Quarter Sessions. Owing to an unavoidable accident the counsel who held my brief was not there in time, and nothing could be done without the notice of appeal which he had in his possession. The Recorder of the Court (in spite of the fact that the police had given formal notice that they were not going to oppose the appeal, thereby giving me the day) expressed his opinion that I had treated the Court very disrespectfully, and intimated that he would only adjourn the case on condition that I asked for no costs against the police. Seeing that there was no other way of gaining justice, to which I thought I was entitled, I consented to this arrangement, and the case was accordingly adjourned until the next Quarter Sessions. On October 28th, the date of the next Court, I again appeared, with counsel, and within three minutes from the reopening of the case gained my appeal, and the conviction was quashed. But as I had agreed to "conditional justice" on my previous visit to the court, which robbed me of costs against the police, the appeal, though won, cost me something over £70. I suppose that I have only received justice, because I hardly think it likely that any motorist in the year 1904 will receive more; and, after all, justice was only conditional. All the same, it seems to me that the appeal of which we hear so much is a luxury beyond the reach of the average motorist.—Yours truly,

R. F. Dickerson.

OVERHEATING TROUBLES.

To the Editor of *The Motor-Car Journal.*

Sir,—I have a 9-h.p. single-cylinder Rex car, and have much trouble with the exhaust valve overheating. The water pipes, in my opinion, are of too small a bore, being only ½ in. in diameter. The pump is a rotary cog-wheel pattern, chain driven. Would a centrifugal pump improve matters? Would it be any advantage to fit larger pipes, taking into consideration that the bore of the connections with the radiator is only ½ in. diameter? The ignition is make and break with trembler coil. Would it be an improvement if I fitted a wipe contact, as the inlet valve does not overheat?—Yours truly,

A. E. Coleman.

A NOISY ENGINE.

To the Editor of *The Motor-Car Journal.*

Sir,—I have a 6-h.p. (Dion engine, Panhard gearing), new six weeks ago. When I am in top gear, and have to apply foot brake down hill, there is a clattering, just like a lot of tin cans, in the second and third speeds. When I apply foot brake there is really no noise at all; whatever noise there is comes from the clutch somewhere, but where I cannot find out. I should feel obliged if you could help me in this matter.—Yours truly.

H. W. P.

[With reference to "H. W. P.'s" letter, it is rather a difficult matter to state trouble, as there are so many different methods of connecting clutch to gear box. Having had similar trouble with a car that was connected by means of a claw, it was found to be fitted rather slack, and when brake was applied at top speed the rattling commenced. This we remedied by fitting small steel plates to the sides of the claw, and found this to overcome the nuisance.]

THE STORAGE OF PETROL.

To the Editor of *The Motor-Car Journal.*

Sir,—The following brief description of the system of storing petroleum spirit I have adopted may be of interest to those motorists who are so far away from petrol depots as to find it necessary to lay in a large store. I procured a strong galvanised iron tank having a capacity of 120 gallons. Into one side of this I inserted three pipes, one an inch and a quarter in diameter, through which, by means of a funnel and an ordinary oil pump, the petrol is drawn from the barrel and conveyed into the tank. Near this is a small quarter-inch pipe. Then a three-quarter inch pipe extending down within half an inch of the bottom of the tank. All three of these pipes are screwed in, and made secure against leakage under pressure. I then buried this tank about eighteen inches under ground in front of my stable, the aforesaid pipes being long enough to extend up to six or eight inches above the surface. A piece of rubber hose is attached to the three-quarter-inch petrol pipe, and a box with hinged cover on top, with hasp and staple for lock, encloses all these pipes. Into this tank I put something over a hundred gallons of petrol at one filling. When I wish to draw out petrol, I simply attach an ordinary bicycle pump to the air pipe and force air into the tank until the petrol runs out. This is quickly and easily done, and the entire arrangement is found to be both a safe and convenient way of storing petrol, and is secure against a possibility of waste by evaporation, provided the valves are kept closed when not in use, and the enclosing box kept securely locked.—Yours truly,

Up-Country Motorist.

THE RULE OF THE ROAD.

To the Editor of *The Motor-Car Journal.*

Sir,—It is all very well for "Cockney" to say that "the only side on which trams should be passed is on the near side between the car and the kerb of the footpath," but I should like to ask him what he would do on the road between Isleworth and Twickenham, and on many of the other routes of the electric tramways on the west side of London where the tram lines are laid within a few inches of the footpath, rendering it impossible for any vehicle to pass on the near side? I consider the way the tramway company has been allowed to monopolise the roads in these districts is simply scandalous.—Yours truly,

A Twickenham Motorist.

The Chief of the Fire Brigade of Brooklyn, U.S.A. on his 24-h.p. Locomobile Petrol Car—one of the few vehicles legally permitted to exceed the speed limit.

EXPERIENCE WITH THE REXETTE.

To the Editor of *The Motor-Car Journal.*

Sir,—One of your correspondents in the *Journal* of the 29th ult. inquires for information *re* the Rexette. My experience, which has extended over 10,000 miles, may be of value to him. The machine has been running consistently well since last March, and I have had no trouble other than an intelligent amateur could put right. The engine, gear box, and transmission have given no trouble, nor do I expect any in that direction. The gear box I look upon as practically indestructible, and seems to have an overplus of reserve force out of proportion to the strain likely be borne. I have the same clutch leather as when I had the machine, and it has received no attention except a dressing of hot bird lime, which acts well when the leather gets polished and preserves the same from wet and too much oil. The speed of my machine is over that which the makers claim (O *rara avis*), and I have ascended all the principal hills in the midlands with a passenger up. The parts are very accessible, and it is only ten minutes' work to remove the back body, and the engine, gear box and clutch can be easily removed by quite an unskilled person. The

Digitized by Google

consumption of petrol works out at about thirty-eight miles per gallon for two persons.

The comfort of the machine is very marked, and many degrees removed from the every day tri-car, though in price the matter is not so apparent.

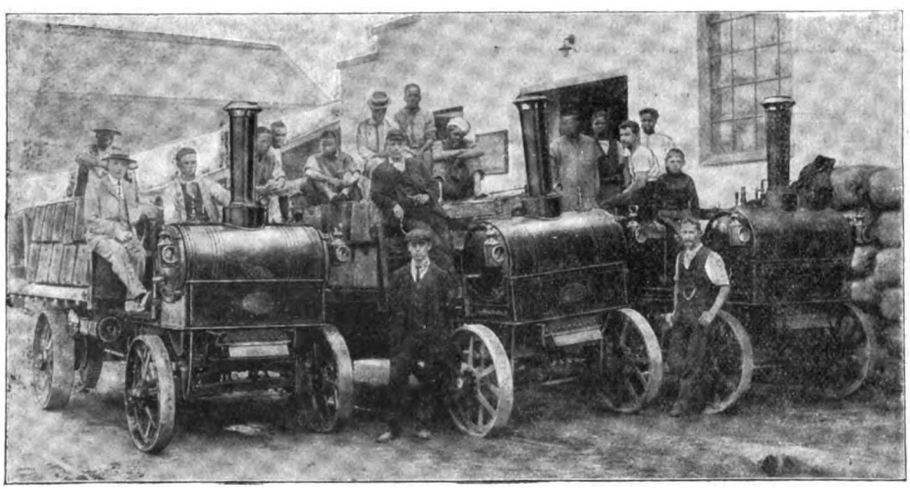
After a Rexette comes at least a ten-horse car in point of speed; five and six h.p. cars are passed on the road with great ease. The general finish of the machine and workmanship are very good and I must say quite different from some of the earlier machines. I am perfectly satisfied, and so are several friends who also have Rexettes. I should be pleased to answer any further queries through your popular *Journal*.—Yours truly,

FOSSE ROAD.

BRITISH v. FOREIGN CARS.

TO THE EDITOR OF *The Motor-Car Journal*.

SIR,—I am entirely in accord with the remarks of Mr. Charles Jarrott upon the subject. One of the chief reasons why the English-made motor-car is not to the fore as much as it might be, outside trade circles, is that we have as yet no factories in this country turning out cars so well, to standard patterns and in such quantities as, for instance, Panhards or the German-Daimler Company.



Even in the case of the much-discussed light car movement, the number of cars that are of entirely English design and construction is insignificant. Their names are legion, but they constitute the product of the foreigner, with very few exceptions.

In my opinion, we have in the automobile industry too many recruits from the ranks of the cycle trade, who fondly imagine they can design as well as the continental manufacturer. This is a business where mechanical ingenuity of a very high order is necessary to success. Give me, therefore, a locomotive or marine engineer in preference to any cycle maker.

There are those who may think I am straying from the point, but this is, I am convinced, at the root of the matter. Simply owing to lack of knowledge large sums of money have been wasted upon inefficient and faulty types of automobiles, but in France very few firms indeed have had, as here, to continually raise fresh capital—or "go under." Look at the ever-increasing numbers of "motor-experts" in this country who do more damage than anything else in repair work, and who cannot mend a perambulator, much less an expensive motor-car. Again, when one goes to the various automobile exhibitions, the dapper attendants are often quite unable to furnish correct information upon even the smallest details connected with the vehicles they wish to sell.

There are a few excellent cars designed and manufactured throughout in England by experienced engineers, but we require efficient organisation, no figure-heads, and standard types to make British vehicles the success they would then deserve to be.—Yours truly,

E. H. OWEN.

The Yorkshire Patent Steam Wagon Co. have lately supplied no less than seven steam vehicles to the South African Breweries Co. The above illustration depicts three of the vehicles in use at Durban.

TO THE EDITOR OF *The Motor-Car Journal*.

SIR,—Mr. Charles Jarrott's instructive letter in your last issue again demonstrates the apathy of English manufacturers towards the motor industry. He tells us that Continental factories, in order to meet the big demand for cars, have trebled—nay, quadrupled—their outputs, whilst the outputs of the various English companies are ridiculously insignificant. So successful are the French firms that five agencies have been established in London, who together have sent no less than 1,200 cars into this country this year. Long before, and since, the motor industry took root in this country the daily Press appealed in its strongest language to capitalists and manufacturers to seriously review the commercial statistics of the world, which were specially prepared for them by experts, to show them how far they were being left behind. With drowsy indifference they read them, and with the same drowsy indifference they put them on one side. Germany was our first great rival, then America, and now, alas! France. And let it be said at once that every one of these countries are holding on with the greatest tenacity, not only to the advantages they have already gained on us, but are making supreme efforts to oust us altogether and wrest from us our world-wide prestige. Everyone knows the value of prestige! Whatever may be said of racing, a big success has an incalculable influence for good, not alone on the particular firm which obtains it, but also on the country's products which it represents. The Gordon Bennett Cup, the Gaston Menier Trophy, and the International Trophy for Motor-Boats were won by Mr. S. F. Edge; and, although he is reviled by many for taking his defeats too seriously, he has undoubtedly done more than any other man in England to obtain that prestige which she now enjoys.—Yours truly,

OWEN JOSEPH.

TO THE EDITOR OF *The Motor-Car Journal*.

SIR,—I notice a letter from Mr. Charles Jarrott in the *Journal*, which appears to be written with the idea of belittling and running down, in every possible way, the big efforts that are being made by the British manufacturers to hold their own in the motor business. If he had carefully studied the recent competitions held in this country, both on land and water, he would have plainly seen that English manufacturers did more than hold their own. I need only refer him to the Sun-Rising Hill Climb, where English manufacturers decisively beat cars of all makes manufactured abroad, including those of greater horse-power. The same thing took place in the Automobile Club's Reliability Boat Trials in Southampton Water, English boats and English engines carrying off the majority of the honours. Again, what about the International Cup? This was won by an English boat—admitted technically it has gone to France, but the real merit and victory belongs to England.

What about the Bexhill speed meeting? Here again successes for English cars. Then let us refer to Portmarnock; again all the big races there were won by English cars. Then remember Blackpool; as is well known, an English car here did the fastest time at the meeting, and most of the events, if the rules had been adhered to, would have fallen to English manufacturers.—Yours truly,

GERALD FARQUHARSON.

TO THE EDITOR OF *The Motor-Car Journal*.

SIR,—Referring to Mr. Jarrott's letter on the above subject in your issue of November 5th, it appears to me that he has taken an entirely erroneous view of the whole question.

My figures were taken from the Board of Trade returns, and these, through a mistake, as I pointed out, apparently indicated that the British manufacturing motor trade was going back instead of, if the returns were taken correctly, that it is on the upward grade. It seemed to me as one interested in this country's manufactures, that any Board of Trade return which did not do our country justice should have the error pointed out.

Your correspondent apparently looks at the matter principally from a professional racing point of view, and whilst no doubt being exceedingly interesting it is not quite the view that the country must look at it from. I dealt with the matter in a far broader way than merely the question of which country has had the greatest sporting success during the current

Digitized by Google

year. I sincerely hope that Britain will have better success next year on the sporting side of motoring, but I see no reason, because its success has not been overwhelming this season, that mis-statements as to its actual trade should appear uncontradicted in the public press.—Yours truly,

S. F. EDGE.

NON-SLIPPING TREADS.

TO THE EDITOR OF *The Motor-Car Journal*.

SIR,—Would some of your readers who own light cars kindly advise me if they know of any non-slipping treads or covers that will not slow the car? Having tried two kinds, I am reluctant to keep on buying and trying. The Walwork covers are very good where there is a reserve of engine-power. The Wilkinson treads are, according to my experience, somewhat weak at the sides. Mine is an 8-h.p. M.M.C., and hitherto I have found that covers take about six to eight miles an hour from the ordinary speeds.—Yours truly,

NORFOLK.

STEAM CARS.

TO THE EDITOR OF *The Motor-Car Journal*.

SIR,—In view of the treatment of steam cars in the Blackpool speed contests held last month, I notice that up to now the committee in connection with these trials have not given any answer to the various letters on the subject which have appeared both in the automobile and other periodicals. It would certainly be more satisfactory if the authorities would give some explanation through the medium of your valuable paper.—Yours truly,

F. WILKINSON.

FRAME CONSTRUCTION.

TO THE EDITOR OF *The Motor-Car Journal*.

SIR,—There has been very considerable variation in the construction of frames for motor-cars, and a final type has not yet been arrived at. The forms of construction which have received extensive trial include the following:—Tubular steel, angle steel, channel steel, steel flitched wood, plain wood, pressed steel, and steel tube with wood filling. All these forms are still more or less in use, but some are declining in popularity, while others are gaining. As regards the tubular frame construction, the main objection to it is the difficulty of properly fastening the mechanism to it. Plain angle steel is also rarely employed, as angle steel lined with wood furnishes a construction better able to withstand shocks and weighing less for a given strength. The steel flitched wood frame was almost universal with leading French makers until a year or so ago, but now pressed steel construction seems to be in the lead with these same makers. Pressed steel frames necessitate a more expensive manufacturing equipment than any of the other forms of construction, and if such frames should prove mechanically superior to the other kinds, they are likely to gain in popularity as motor-cars are manufactured in greater number after the same pattern.

The conclusion to be drawn from the results of experiments so far and the various changes made is, I think, that a combination of wood and steel in some form makes the best frame for motor-cars, the steel providing the necessary rigidity for connections, making it impossible for the parts attached to the frame to be displaced therefrom, and the wood giving the whole frame a certain elasticity, which is beneficial alike to the life of the frame and to the proper operation of the machinery placed on it. That a combination of wood and steel makes the most durable structure for a road vehicle had already been discovered by carriage builders, and has now been re-affirmed by the experience of motor manufacturers. There are, however, a great many possible variations in the combination of wood and steel for this purpose, and the problem now is to determine the most suitable combination, having regard to cost of manufacture, strength for a given weight, and durability.—Yours truly,

A. C. ARMSTRONG.

THE CONTROL MECHANISM OF MOTOR-CARS.

TO THE EDITOR OF *The Motor-Car Journal*.

SIR,—It is the duty of every motorist to strengthen, as far as he is able, the just claims of the motor-car to be the safest means of road transportation, and it is essential that as little basis as possible be furnished for the exaggerated reports of automobile accidents which go the rounds of the daily press. One occasional cause of accidents which throws entirely undeserved discredit upon the motor lies in the attempts which motorists sometimes make to drive vehicles of makes other than the one to which they are accustomed. There would be very little danger in this were it not for the fact that each make of car possesses a control system varying from almost every other.

Variations exist, among cars from different factories, in the most fundamental and vital control functions, and not infrequently a certain motion upon the part of the driver may result in exactly opposite effects upon cars of two different makes. In a sudden emergency the motorist handling a strange car, although he may know, after an instant's deliberation, just what he should do, will, in the absence of time for consideration, very likely fail to do it and an accident may result. He is more likely to act subconsciously and perform the act which a long use of his own car has taught him is appropriate to meet the conditions at hand, and this act, performed on another car, may be just the wrong thing.

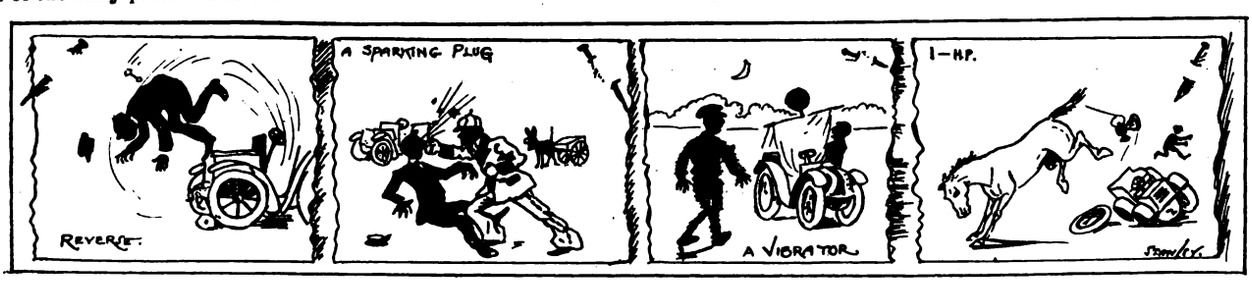
The purchaser of a new car is seriously embarrassed for a time, and his driving rendered less safe than it otherwise would be, on account of the fact that his new car, unless of the same make and type as his old one, will probably possess entirely different methods of control. He will have to unlearn the habits of driving which have become almost second nature to him, and the difficulty of so doing will be greater in proportion to the length of time that he has driven his former vehicle. During the process of transition he will be a less safe driver than he previously was. Standardization of systems of control, even if only carried out partially, would do much to reduce the danger and inconvenience of changing machines, and it would seem that the manufacturers should get together and agree upon some uniform practice as to what operations should be performed by the hands and what by the feet, where the mechanisms controlling certain functions of the control should be placed, and in which directions these mechanisms should be moved to produce certain effects. There seems to be no obvious reason why some approach toward uniformity in these and perhaps other features of the control may be hoped for; at all events, it is certain that there is no shadow of reason for the diversity of methods for accomplishing identically the same results which motor-cars now present.—Yours truly,

SIMPLICITY.

REPAIRS.—"Amateur" would be glad to hear of a large firm of motor-car repairers characterised by reasonable charges.

FOOTWARMER FOR MOTOR-CAR.—In answer to several enquiries, the makers of the footwarmer described in a recent issue are Messrs. Desponts and Godefoy, 136 bis, Rue Victor Hugo, Levallois-Perret, Paris.

STEAM CARS.—Mr. W. T. Warne writes that he will be glad to exchange notes with Mr. E. F. Calland. His address is 24, Great Sutton Street, E.C.



NON-SKIDS.—Replying to D. Millar, full particulars of the L'Empereur Non-skids can be obtained from Messrs. Mann and Overton's, Victoria Garage, 7a, Lower Belgrave Street, London, S.W.

WOLVERHAMPTON CLUB'S HILL CLIMB.—With regard to the treatment of steam cars in this competition, Mr. J. B. Dumbell writes to suggest that a mistake was made in the method adopted by the committee.

STEAM v. PETROL.—"Bishopsbourne" writes:—Would some of your correspondents kindly give particulars of their experience of the relative cost of working steam cars v. petrol and cost of mileage on a gallon of oil? A friend of mine, an engineer, bought a good second-hand petrol car, and says it cost him £50 for twelve months in repairs. I do not think steam can come up to that.

THE VANDERBILT CUP RACE.—The Packard Motor Car Company, of Detroit, Mich., U.S.A., write us pointing out that in the report of the Vanderbilt Cup Race in the *Journal* of the 15th ult. their Packard car driven by Mr. Schmidt is by an oversight referred to as a Panhard. With reference to the statement that "out of the five American entries only one was classified," they write, "Our 24-h.p. "Gray Wolf" was immediately behind and in close proximity to the Pope-Toledo car when the race was declared off."

NON-SKID BANDS.—The "Otto Bennett" Motor Company write us as follows:—"We beg to call your attention to an article in your paper of the 5th Nov., whereby you illustrate a detachable non-skidding device which is supposed to be put on the market by the Shaw Motor Tyre Tread Company. We beg to inform you that this band is the Otto detachable band, of which the Shaw Motor Tyre Tread Company have been granted the license to sell."

Some Motor Terms Silhouetted.

COLD WEATHER PRECAUTIONS.

A NEW ANTI-FREEZING MEDIUM.

By Henry Souther.

During the last severe winter the writer made some practical experiments in the way of finding out what mixture could be used in the cooling system of motor-cars that would prevent freezing and at the same time not be in any danger of injuring any part of the automobile. Various salts, glycerine and wood alcohol were considered. Wood alcohol was chosen for the first experiment because there was not the slightest chance of its injuring any machine. The success was such and the duration of the test was so long that nothing else was tried. For the benefit of those, however, who care to run a vehicle during cold weather, the writer gladly gives the results of the experiments. Perhaps the most valuable use that can be made of these results is from now on, at a season of the year when riding is very acceptable during most of the day, but with light frosts at night and a sufficient degree of cold to ruin a cooling system if containing water only.

The character of the experiment conducted was this. First—A set of laboratory freezing experiments to determine what percentages would freeze under artificial conditions. This showed at once that it was possible to use wood alcohol and water and resist almost any degree of cold. Second—The next question to answer was whether or not the wood alcohol would separate from the water and waste away so fast that the scheme would be too expensive. Of course, this possibility amounted to but very little in extremely cold weather, but in mild days it was felt that considerable alcohol might be lost. To demonstrate this point a water-cooled car was taken, and about 18 per cent. of wood alcohol was added to the water. The whole system contained

about seven gallons. Various experiments were made by connecting a bottle with the top of the radiator into which a pipe led from above the water level, the idea being that any vapour formed would rise into the cold bottle and condense. It was found that, except under extreme conditions, no vapour at all arose. By extreme conditions, I mean any mild day, allowing the engine to run standing still, there being no fan for cooling.

This immediately led to the thought that it might be possible to entirely close the system in cold weather, thus obviating any chance of loss by boiling away. This was done and a pressure gauge put on and connected with the system. The highest pressure obtained at any time and under very severe conditions was six pounds. This means that there are some vehicles that can be run with the use of alcohol without any loss whatever, there being a certain number of types that run with a closed system. It is also quite possible that many cars can be run with a closed system that now have relief tubes. The safest way to find this out in an inexpensive manner is to take a small bit of rubber tubing, fitting the end of the blow-off pipe, put a wooden plug in one end of it, and slip the other over the tube lightly. Any pressure that would injure the car at all would blow this off and prevent injury.

Later in the season, when the temperature was as low as 15 degrees F. below zero, 33 per cent. of alcohol resisted freezing perfectly, even when the machine was left out of doors over night. Within the last week or two the writer has been using 32 per cent. of alcohol, with the temperature about 50 and 60 degrees F., with a result that the mixture did boil slightly, but not enough to be dangerous. This simply shows that at this season of the year it is not necessary, nor is it wise, to add much alcohol. It is not probable that the temperature, just now, or up to the 1st of December, will drop below 10 degrees F., in which case 15 per cent. of alcohol is enough. As the season progresses and December is reached, and zero temperatures are possible at any time, nothing less than 25 per cent. would be safe.

The question will be asked at once how to know whether or not the per cent. of alcohol is diminishing in the water system. With nice laboratory instruments, it has been easy for the writer to study this matter, and easy to tell just how much loss there has been. For the ordinary motorist it is not easy, as the specific gravity varies very little from pure water, and it takes a finer instrument and better conditions than are likely to be found under ordinary circumstances. After all, the best and easiest way is by the odour. If the motorist will mix up, say, a 20 per cent. and a 10 per cent. solution, put them in bottles and keep, he can have a standard of comparison that will really be quite accurate, with the assistance of his nose. Even with the open system, the circulation and the cooler becoming quite hot in mild days, the loss of alcohol by boiling is extremely small. It is apparent that the alcohol does not go away by itself, but that the mixture of alcohol and water goes together, so that the percentage left remains practically the same.

Simultaneous with this practical using test another freezing experiment was carried out. A number of test tubes were made up containing varying percentages of alcohol from 4 up to 30 per cent. in steps of 2 per cent. These were placed in a basket outside a window in a very cold place, and in the basket also a maximum and minimum thermometer. At 7 o'clock each morning the tubes were examined and the highest percentage of alcohol frozen noted. The results from slow and natural freezing like this, and duplicating the condition of actual use, were a little different from the artificial laboratory freezing experiments. The results obtained are shown on the accompanying curve. In drawing this curve the writer has been conservative, and the results possible are a little better than the table. By consulting this the motorist will be able to see at a glance about what percentage of alcohol it is necessary to use, the only caution being not to add any more than is necessary. Alcohol is not dangerous in any way.—*The Motor World.*

CLUBS AND ASSOCIATIONS.

YORKSHIRE.

On Thursday of last week this club held a successful smoker in its Rooms at the Great Northern Hotel, Leeds, being the first social event of the winter programme. Mr. Hepper was in the chair and presided over a gathering of nearly a hundred. In his address Mr. Hepper remarked on the rapid growth of the club, and pointed out that it was the most powerful provincial club existing, and that it was considerably extending its powers by the formation of branches in other towns of the county. He also mentioned the general meeting on the 10th inst., and the fourth annual dinner on the 2nd prox. Following a musical programme came the distribution of the certificates and prizes given in the recent Wentworth Woodhouse speed trials. The silver afternoon tea service was won by Mr. Alf. Masser, Leeds, and the silver sugar and cream service by Mr. Underwood, Hull. The silver cup presented by Mr. Winn, and held last year by Mr. Faiers, Bradford, was awarded to Mr. Norman Bayless for the meritorious performance of his Renault car. Mr. Farnell attended to take away the massive bronze trophy "Pro Merite," presented to the club by Mr. Kirk for cars in Class 5 and held by Mr. Walter Jackson, Bradford, and won this year by Mr. Farnell, who spoke a few words in reply thanking the club for the trophy. The presentation of a large and handsome case of cutlery and a gold stop watch was made by Mr. King (Vice-President) to the hon. sec., Mr. Alf. W. Dougill, on the occasion of his marriage. Mr. King said that the club were very pleased to thus mark their approbation of the energetic and laborious work entailed in connection with the club. In replying Mr. Dougill thanked the club very much for their present, but thought that the work would be much harder if it were not for the valuable assistance given by the Committee, Vice-President and Hon. Treasurer. A hearty vote of thanks was accorded to Mr. Hepper for his duties in the chair, the whole company joining in the singing of "He's a jolly good fellow."

MANCHESTER.

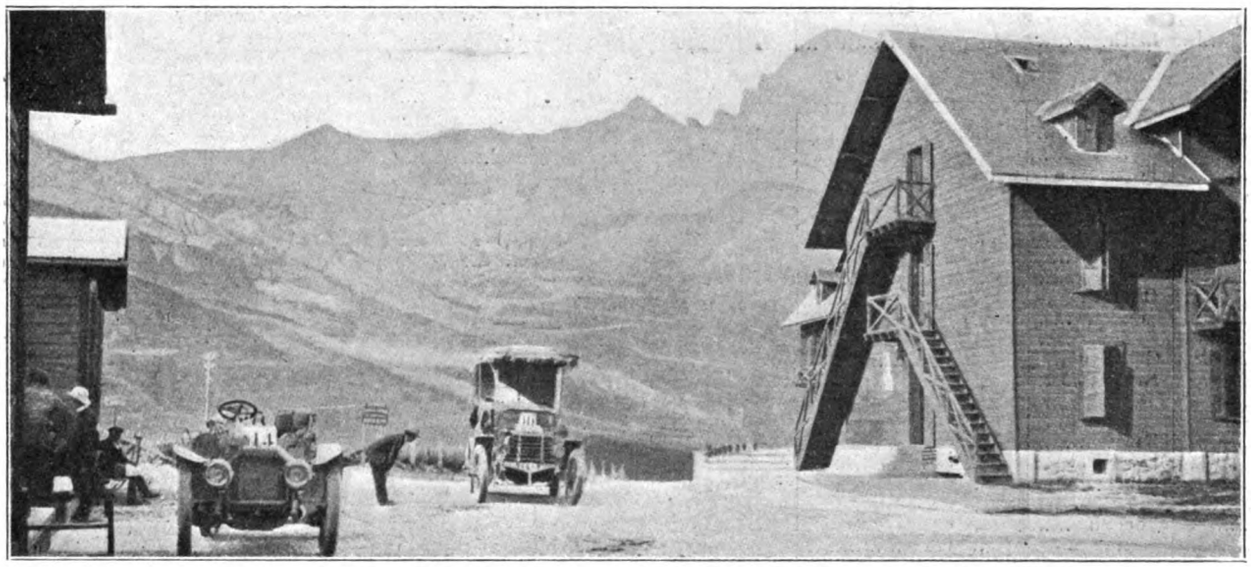
The members of the Manchester Automobile Club held their first house dinner this season at the Midland Hotel, Manchester, on October 31st, about sixty members and friends being present. After dinner Mr. Frederic Smith, the chairman of the club, read a paper entitled "Some Reminiscences of the Road."

Mr. Smith described some adventures and impressions which he himself had experienced on the road, and warned fellow motorists against dray horses drawing heavy loads, and especially against the chain horse, which in its panic might swing across the road and thus block the only portion left to the motorist. Mr. Smith then referred to the methods of the stolid policeman who controls the traffic, and in many instances seemed to evince a partiality for slow-moving traffic and to hold up the quicker vehicles. It was suggested, as a possible explanation, that the policeman himself must at one time or other have been a drayman, and therefore fully familiar with the practice of draymen, which, now he had become empowered with the majesty of the law, he sought to enforce. Whilst on the question of controlling the streets, Mr. Smith referred to the dangers and delays on the roads caused by draymen driving their vehicles in the centre of the road, which meant that the motorist, to pass, must either drive into the teeth of approaching traffic or into the gutter. He suggested that it would be better for all parties concerned if it were the rule of the road for slow vehicles to keep to the kerb and to leave the

Digitized by Google

centre of the road free for fast traffic, and it would certainly save much of the *volapuk* one sometimes hears from drivers of horse vehicles.

In regard to the ubiquitous bicyclist the lecturer thought that motorists should be considerate towards them. They ought to remember that the bicyclist came before they did and had suffered much persecution, and it was just as times were improving that the motorist came along and insisted on sharing the road with him, which naturally caused the bicyclist to be rather lukewarm in his affection, more especially as he knew that by giving way he would shortly be eating the dust raised by the motorist. In conclusion the claims of the dog were considered. The claims of the dog to intelligence were disappointing. He has always been credited with almost human powers of observation and deduction, and yet he will barely take the trouble to get out of the way of the wheels of the motor. Other times he will hurl himself furiously at us, evidently under the impression that a vicious bark will stop the car. How can a motorist blame himself if, after a severe trial of springs and tyres, or risk of damage by swerving round a curve or into a telegraph pole, the dog yet defeats our efforts and immolates himself under the wheels? If this is to be the end, however deeply we regret it, it may lie lightly on our conscience. Let him rest in peace as an example of foolhardiness and misplaced energy.



MOTOR-CAR FATALITIES.

THE Winchester City Coroner has held an inquiry into the circumstances of the death of Mrs. Hester Condon, who died at the Royal Hants County Hospital through falling beneath a motor-car in Kingsgate Street. Mr. C. E. Godwin represented Mr. Slade, the driver of the car; and Mr. Alfred Bowker appeared for Mr. Boyd, the owner. After hearing evidence, the coroner said in the present case there was some discrepancy as to the speed of the car. He generally took the two extremes that were given, and drew his own conclusions. Mr. Slade passed Mr. Northall's shop at eight miles an hour, and he said that the road was clear, and there was nobody about. That observation would have been a proper one if it had been a country road, but in the narrow streets of Winchester an answer like that, even if the evidence was different, would not satisfy him. The narrowness of Winchester streets and the fact that people often suddenly stepped across from one side to the other must be taken into account, and it must not be assumed that because nobody appeared to be about a driver of a car was justified in going along at anything like a good pace. Winchester was full of narrow streets and sharp curves, and the people had to rely upon the help of the motorist, who should be extremely careful how he proceeded. He believed in that case they could take it as a fact that the hooter was properly sounded, and he thought that if the deceased had known what she was about there would have been no inquest. Whatever the result might be he hoped it would be an additional warning, if warning were needed, to those who drove motor-cars, especially in the narrow streets of the city, and that every care would be taken. Proper care seemed to have been exercised in that case, and it was unfortunate that the deceased acted as she did. The jury handed in a verdict of "Accidental death," and expressed their unanimous opinion that no blame whatever attached to the driver. The Coroner said he entirely agreed with that remark.

THE Berks coroner held an inquest at Hurley on Monday on the body of Thomas Edwin Overall, a little boy who was knocked down by a motor-car and killed near Hurley on Friday of last week. Mr. Noble, of Bayswater, said he was with his son in the car alleged to have knocked the boy down. He had made a statement to the police and signed it, which bore out in every detail the evidence given by some children who were on the spot. He now contradicted the statement and said he did not know of any accident. His son, who was driving, also gave somewhat contradictory evidence, on which the coroner commented. After half an hour's deliberation the jury returned a verdict of manslaughter against Stanley Monro Noble, the driver of the car, and he was liberated on bail.

CLAIM AGAINST MOTOR-CAR BUILDERS.

THE Lord Chief Justice and a special jury, sitting in the King's Bench Division, on Tuesday concluded the hearing of a claim by Mr. Assheton Leaver and Mr. Thomas A. Callum, motor-car engineer, to recover damages from Humber (Limited), of Beeston, Notts., for breach of warranty in regard to a motor-car. After the hearing of expert witnesses, the Lord Chief Justice, in the course of his summing up, said that Mr. Leaver was not entitled to return the car, but if the jury found that either from bad workmanship or the use of bad material it was not reasonably fit for use as a motor-car, then he would be entitled to recover such reasonable damages as they might decide on, in view of the fact that he had given £570 for the car. It would also follow that the company could not recover on their counter-claim. The jury returned a verdict for the plaintiffs, with £100 damages. Judgment was entered for the plaintiffs accordingly on the claim and counter-claim.

Motoring in the French Alps. 6,800 feet above Sea Level. *[L'Automobile.*

A MOTOR-CAR CONVICTION.

BEFORE the Lord Chief Justice, Mr. Justice Kennedy, and Mr. Justice Ridley, in the case of "The King v. the Justices of Berkshire (ex parte the Earl of Craven)," Mr. Horace Avory, K.C., applied on behalf of the Earl of Craven for a rule calling upon the justices of one of the petty sessional divisions of Berks to show cause why a writ of certiorari should not issue to bring up a conviction under the Motor Car Act of last year with a view to its being quashed. The learned counsel said the grounds of his application were that the conviction was bad on the face of it, and that the justices had no jurisdiction at all to convict. The magistrates proceeded ex parte, and although that was not a ground for certiorari it was a ground for criticising their action. After hearing further explanation a rule was granted on two points in reference to the conviction not being good on the face of it.

AN inquest was held at Bournemouth on Saturday concerning the death of a young French governess, who was fatally injured by coming into collision with a motor-car while cycling down Boscombe Hill on October 29. After hearing the evidence the jury returned a verdict that the young lady met her death from contact with a motor-car brought about by the negligence of the driver in leaving his correct side of the road. They also recommended that the authorities should limit the speed of motors to eight miles an hour through town thoroughfares.

THE Horstmann Gear Company, Limited, has been registered with a capital of £1,000 to acquire from Messrs. S. A. Horstmann, A Horstmann, E. H. Horstmann, G. O. Horstmann, and W. T. Edgar the benefit of a certain existing invention relating to the speed gear of motor-cars.

REFERENCE is made in the "Motor Age" to a model motor-car built at Sharon, Minn., U.S.A., in which common white lime is used as fuel. The lime is said to be placed in an iron tank having a capacity of a quarter bushel, and water is dropped upon it from an iron receptacle on top of the tank. The resulting vapour, which is produced in great quantities and at a high pressure, is conducted to a small engine which works similarly to a steam engine.

TO CORRESPONDENTS.

All communications intended for insertion in this Journal or relating to Editorial matters should be addressed to THE EDITORIAL DEPARTMENT, MOTOR-CAR JOURNAL, *39 and 40, Shoe Lane, London, E.C., and must be written on one side of the paper only. Letters must in all cases be accompanied by the name and address of the writer, as no notice will be taken of anonymous communications.*

The Editors cannot undertake to return MSS. or drawings, although every effort will be made to do so in the case of rejected communications. Where such are regarded as of value, correspondents are requested to retain copies.

To insure insertion communications and contributions must be in the Editor's hands by Tuesday forenoon of the week in which the same are intended to appear. Disappointment may be caused by non-compliance with this rule, and to avoid this earlier receipt, if possible, is necessary.

The Editors do not hold themselves responsible for the opinions expressed by their correspondents, or for statements and facts which do not appear in the editorial columns.

The Editors and Publishers beg also to state that they will accept no responsibility for unsolicited contributions, even if used, unless payment for same is directly specified in forwarding, and the terms arranged before publication.

THE

Motor-Car Journal.

VOL. VI.] LONDON, SATURDAY, NOVEMBER 19, 1904. [No. 298.

Published Weekly by CORDINGLEY & CO., 39 & 40, Shoe Lane, London, E.C.

COMMENTS.

MONDAY last was the anniversary of the adoption of the Act which is often called the "Magna Charta" of British automobilism, and the founder members of the A.C.G B.I. celebrated it in characteristic British fashion by dining at their headquarters. Time was when the event was celebrated by a run to Brighton, and we remember the early adventures, when, commencing early in the morning, passengers on the cars thought themselves extremely fortunate if they reached Brighton in time for the evening dinner. In connection with the event, the Club have issued a special pamphlet, giving the history of the official organisation and some early incidents in connection with its inception. This will have some sort of historical interest, and form an interesting contribution to the growing literature of the subject. While the great tour has been abandoned, and having regard to the weather of the past few days, we may consider ourselves fortunate in that, the idea of a long distance tour under official club auspices was carried into effect on Monday, Captain Deasy having been the first to request the attendance of official observers under the new regulations of the Club, which has now consented to take long distance runs under its own observation.

◆ ◆ ◆

Captain Deasy's New Exploit.

CAPTAIN DEASY'S run of 4,000 miles under Club observation will thoroughly test the Martini car, which has already achieved triumphs on the Continent. He will be relieved on the daily runs of 200 miles by Mr. E. G. Williams, and everyone will hope for their success in accomplishing the heavy task. The day's work will extend to thirteen hours, two hours for cleaning, replenishment, and adjustment, an hour for luncheon, and ten hours for driving at the rate of twenty miles an hour. Not only will due notice be taken of all stops, etc., but the consumption of fuel will also be recorded, so that some useful data should be secured.

◆ ◆ ◆

An Indiscretion.

AN interesting correspondence has lately passed between the committee of the A.C.G.B.I. and Mr. Frederic Coleman, whose association with the White steam car is well known. In the official organ of the club there recently appeared a reproduction of the drawing by Mr. Linley Sambourne for the special certificate issued to the winners in the Reliability Trials. In this the first vehicle in the procession is labelled "To-day," the second vehicle "Yesterday," and further to the rear is a vehicle labelled "Steam," a very indiscreet reference which was quite unnecessary to the purpose in view. Seeing that two of the certificates on which such a sketch appeared were awarded to one particular make of steam vehicle, it undoubtedly detracts from their value for publicity purposes to that firm. It was not the purpose of the club to make such distinction, and surprise has naturally been expressed that such a reflection on steam-cars should have been allowed to have official sanction.

◆ ◆ ◆

Advocate of Steam Cars.

THE incident is all the more regretable, in view of the efforts that are now being made on thoroughly scientific and workmanship lines to perfect the steam vehicle. In several competitions, such cars have made splendid records; they are frequently to be found going well on the road, and their reliability is being attested by users. In view of the feeling engendered among makers of steam automobiles by the system of handicapping adopted in some recent competitions, it is a pity that by an unfortunate oversight anything should have been made public likely to embitter the situation. But, after all, those interested in the steam car industry may take hope, for, as our correspondence columns have lately shown, they are not without advocates ready to come forth and testify to the satisfaction given by many modern vehicles in which the motive power is the agency of steam.

◆ ◆ ◆

The Welsh Club.

WITH a practical enthusiasm that should be imitated by some of the older automobile clubs, the organisation concerned with South Wales and Monmouthshire is developing local interest in the movement, and also proving of tangible advantage to its members. Reference was recently made in our columns to the new motor-house and club-rooms for the convenience of members, as well as those associated with other provincial clubs who are prepared to reciprocate the privilege. The charge for cleaning the cars of members has been fixed at 6d. per hour, and a handbook is being prepared giving details of distances and other information required by local motorists. The new motor-house has become exceedingly popular with the owners of local cars, who use it for both business purposes and pleasure. Several new members have been enrolled, among them being Sir William Thomas-Lewis, Bart., and Principal Griffiths, of the Cardiff University College.

◆ ◆ ◆

Motor-Buses in London.

ANOTHER motor-omnibus has been given a trial in the streets of the Metropolis between Hammersmith and Oxford Circus. The London Road Car Company, Limited, is now running a vehicle fitted with a 16-20-h.p. Germain motor, which, from the experience of the early trips, promises to be a formidable competitor in the race for popularity in such services. Motor-'buses are becoming familiar objects among the traffic of the West End, and it would appear that, practically for the first time, real efforts are being made to introduce the motor as a means of popular locomotion. Hitherto such attempts have been spasmodic and transitory; now, however, several types of vehicles are on the London roads, and many different financial interests are concerning themselves with the experiments that promise a real motor-'bus service in the end. The introduction of the Germain 'bus in this connection is valuable as giving our

Digitized by Google

London public an opportunity of riding in a vehicle that for ease of running and general appearance merits well.

◆ ◆ ◆

Pistols for Motorists.

HISTORY repeats itself; so do the foolish utterances of persons usually credited as leaders in their communities. Not only has an American magistrate shown a marvellous degree of prejudice against motorists, but a member of a southern urban district council has lately exhibited a similar ignorance of the inevitability of the motor-car. "If we have no other remedy," remarked Mr. T. Young at a recent meeting of the Southwick Urban District Council, "I shall recommend that everybody keep shot guns and shoot them"—"them" being innocent unsuspecting motorists travelling in the district where Mr. Young is regarded as a man of some importance. Mr. Young has declared what he would do with motorists; he had better not hear what motorists would do with him.

◆ ◆ ◆

Armoured Motorists.

CLAD wholly in clothing of armour plate, and looking like knights of the fifteenth or sixteenth century, two coloured drivers recently created much amusement and amazement in the streets of New York and Brooklyn. Had it not been for streamers attached on the sides of the tonneaux—bearing

the inscription "Friends of Magistrate M. Corneli, do not shoot"—the two fellows might have been taken for crazy men. It was all the result of a combination made by the vice-president of the Standard Automobile Company and Messrs. Smith and Mabley, who thought of playing a joke on the officer who recently suggested that a man who shot a reckless driver was justified in doing so.

◆ ◆ ◆

A Touring Committee.

A NEW committee of the A.C.G.B.I. has recently been formed at the suggestion of Earl Russell, which should be of great value to members of the Club contemplating touring in any part of Great Britain. The programme which has been suggested for their work is an extremely comprehensive one, and will require much careful organisation if it is to be carried out in anything like its entirety. The point with regard to recommending hotels and repairers is one that seems to have practical interest, in view of the discontent that has been expressed by many motorists with regard to the high charges that are constantly being made by some of the leading hotels in the country. Similarly, with regard to repairers, there is, unfortunately, as great a diversity in the scale of charges as in the amount of fines which magistrates seem to inflict upon motorists. These are subjects which the new committee propose to deal with, and we hope that the difficulties of settlement are not beyond their capacity.

An English Mission to Germany.

ON the morning of the 26th inst. Mr. Shrapnell Smith will, on behalf of the Automobile Mutual Protection Association, leave London for Germany in order to make a thorough investigation into the system of road construction that has been developed in that country. He will be accompanied by Mr. John A. Brodie, the City Engineer of Liverpool, and by Mr. H. Schofield, the County Surveyor of Lancashire, so that every confidence will be felt in the report that is brought back Starting from Cologne the party expect to make a very comprehensive survey, and the mission should have a very far reaching influence on the progress of the automobile movement in Great Britain. For, as we have always urged, the improvement of the road must be carried on simultaneously with the development of the car.

◆ ◆ ◆

Motorists in London.

STEADILY the census of motorists within the metropolitan area mounts up, and the figures are becoming formidable enough to bring the most prejudiced opponent to a reasonable frame of mind. Up to the 5th inst. no fewer than 11,558 licences to drivers had been issued by the London County Council, the registrations of motor-cars and motor-cycles to the same date being 4,791 and 3,238 respectively. Two hundred and ninety-three general identification marks had been issued to manufacturers or dealers, showing the continual growth of the industry in London. Of course in these figures no account is taken of the authorities on the outskirts who issue licences to drivers and who register cars which are frequently to be found running within the jurisdiction of the London County Council. These statistics, however, reveal a growth of the trade which indicates a permanent and expanding prosperity.

◆ ◆ ◆

Fog and the Motor.

THE weather of the last few days has been trying indeed to venturesome motorists who have sought to travel by motor-car. Fog has not only rendered open-air driving an unpleasant experience, but it has, as usual, completely disorganised traffic. Among the motorists inconvenienced by the wretched weather conditions prevailing was Prince Arthur of Connaught, who had the disagreeable experience of being held up for the night by a dense fog, which overtook him while motoring in Surrey. He was on the main road at Egham on Sunday night about eleven o'clock when his motor-car driver found that it was unsafe to proceed owing to the fog. With much difficulty they descended the hill leading to the village, and roused a cottager, who guided the Prince to the Catherine Wheel Hotel. After some delay the landlord was awakened, and His Highness supplied with refreshments and sleeping accommodation. The Prince, who seemed much amused at his experience, rose very early yesterday morning and proceeded to London. It would be interesting to have other experiences from motorists who were similarly inconvenienced, or who observed any effects on the driving of their vehicle from the same cause.

◆ ◆ ◆

Inquiries in Scotland.

HITHERTO somewhat inclined to rely on the interest in motors shown by Mr. Graham Murray, the Secretary for Scotland, the motorists north of the Tweed are now likely to be converted to the advisability of the energetic policy pursued on this side of the Tweed, for several county councils are appealing to the Local Government Board for Scotland for the restriction of motor-car speeds within their areas, and inquiries have just been held at Ardrossan and Ayr. In one of these, Mr. Rees Jeffreys made a characteristically clear defence of the automobilists' position, but we are afraid that the opposition on the part of the local authorities will be strong enough to throw over the most reasonable attitude. Apparently the Scottish Club will have to give its most earnest attention to the opposition that is

Digitized by Google

developing against motor-cars in the North of Scotland, and frustrate it by an energetic campaign.

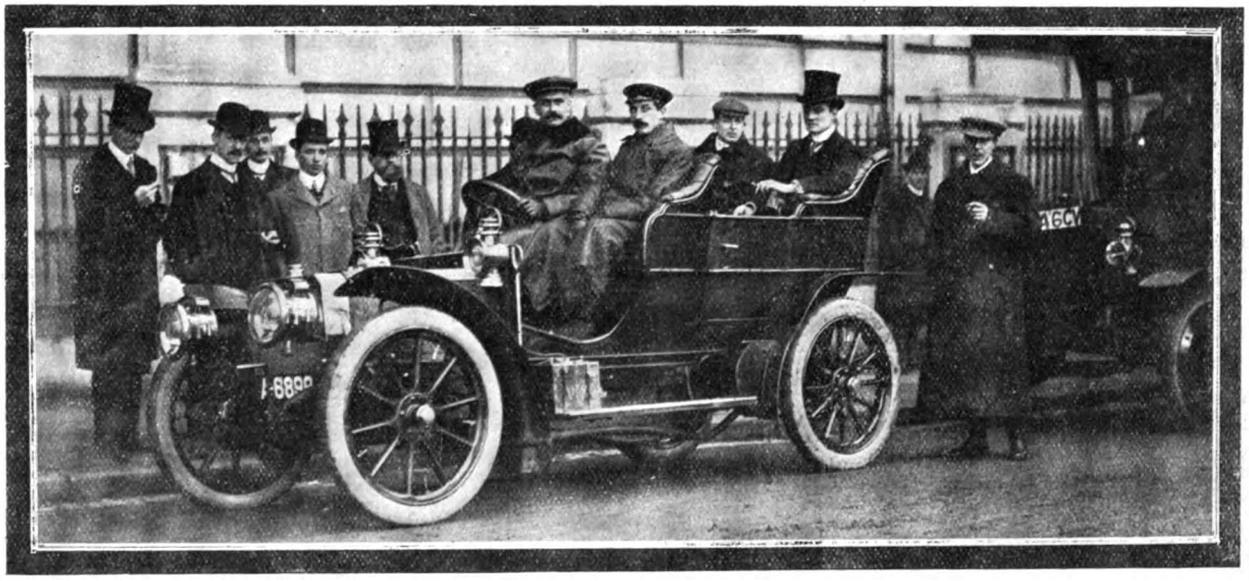
◆ ◆ ◆

Cases against Motorists.

In our correspondence columns this week will be found some letters with reference to the cases against motorists which we have published from time to time. One of our friends seems to think that, in thus giving publicity to the way in which motorists are fined in different parts of the country, we are helping the authorities somewhat; but, as a matter of fact, having regard to the large number of motor-cars now in daily use, we cannot see that the information thus given is likely to render harm to the growing industry. As a matter of fact, the weekly record we publish is useful from two points of view; first as indicating those localities where the police are unusually active, and where magistrates are apparently prejudiced in favour of the ancient form of travel; and, in the second place, it reveals far more adequately than any mere writing could do the unfairness with which fines are inflicted in some parts of the country as compared with what happens in others. As another correspondent points out, what is treated with severity in one part of the country is dismissed with a small fine in another. Thus one of those anomalies which the present year has brought into existence is exposed in an effective way, and we are greatly assisting those who are still dissatisfied with the present state of things. They, after all, undoubtedly constitute the majority of those who are in the habit of frequently using their vehicles.

◆ ◆ ◆

Index Letters.



The senseless, or perhaps we ought to say the haphazard way in which index letters were assigned to the various counties and county boroughs was the subject of much comment months ago, and it has again been brought into prominence by the letter which Lord Portman has written to the Dorset County Council with regard to the letters B F, which have been assigned to that district. It appears that the county funds have suffered and that many motorists have preferred to register their vehicles in other counties, with advantage to the exchequers of those districts. Bearing this in mind the Dorset County Council have decided to ask the Local Government Board to give the matter further consideration with a view to amendment. Under a proper system of classification Dorsetshire would have been D O, and the Holland, the division of Lincoln to which those letters had been assigned, might have been H O; S X might have indicated Sussex, S Y Surrey. and so on, so that the letters should form a distinct clue to the name of the county.

◆ ◆ ◆

Stopping Motorists.

Within the last few weeks it has been made apparent that the Motor-Car Act is even now imperfectly understood. Just as a certain Parliamentary leader once declared that the only way to learn the rules of procedure at Westminster was to break them, so it is becoming increasingly demonstrated that only by contravening the Act can motorists get acquainted with its provisions. But that is an expensive process, as Mr. Dickerson pointed out in our correspondence columns last week when relating his own experiences in connection with a case at Hastings. Similarly Mr. J. R. Gray, of Dalkeith, has discovered that defending a case against him in Yorkshire where the summons was dismissed has resulted in heavy expense. This is one of the weaknesses of the Act; even when they prove they have committed no offence, motorists are seriously out of pocket. If such dismissals also carried the right to costs with them the police would soon become careful as to instituting proceedings. But the present practice rather encourages persecution.

◆ ◆ ◆

Captain Deasy Starting on the 4,000 Mile Run of the 16-20-h.p. Martini Car.

By Ordinary Wayfarers.

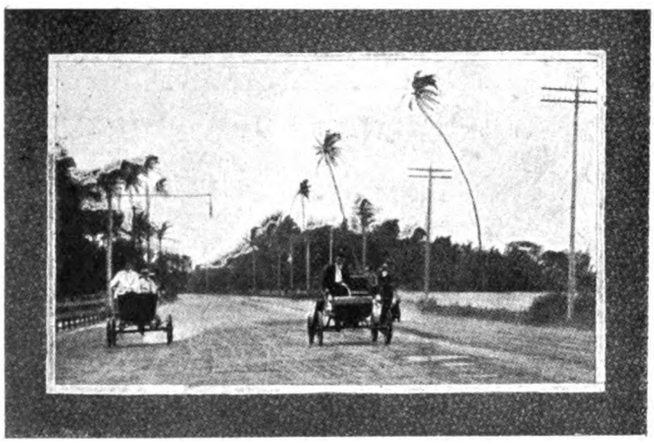
At the Marylebone Police Court a motorist has been fined for refusing to give his name and address to a gentleman who was riding in a cab when the car driven by defendant crashed into it, resulting in an accident. The defence was that he was under the impression that no one but a policeman had a right to demand his name and address. Mr. Curtis Bennett, the magistrate, soon disabused his mind of such a notion by fining him 40s., with three guineas costs, and declaring that anyone had a right to demand the name and address of the driver of a motor-car and the name and address of the owner after an accident. This is a point to bear in mind, for although some writers have supposed there is some ambiguity, the omission of the words "police constable" from Sub-section 3 of Section 1 seems to indicate that anyone may demand the name and address of a motorist who has committed an offence.

◆ ◆ ◆

By Policemen.

A point upon which the police, notably Superintendent Marks, of the Surrey force, need enlightenment is as to the powers of a policeman to stop a vehicle. Mr. A. E. Macdonald has just been summoned at Kingston for refusing to stop when a police-sergeant in plain clothes called upon him to stop

Digitized by Google



when he was travelling on the Fairmile at Cobham. Relying upon the early regulations with regard to light locomotives, the superintendent was apparently unaware of the regulation of the Local Government Board issued this year by which a motorist "shall, on the request of any police constable in uniform, or of any person having charge of a horse, or if any such constable or person shall put up his hand as a signal for that purpose, cause the motor-car to stop and to remain stationary so long as may be reasonably necessary." Even Mr. Cockburn, the chairman of the Kingston Bench, could not convict, and seeing it was clear that the policeman was not in uniform, had to dismiss the case.

◆ ◆ ◆

Notice of Summons.

THE fact that a policeman can take out a summons against a motorist for exceeding the legal limit at any time within three weeks of the committal of the alleged offence is hardly a fair provision. There is thus no need to warn the supposed delinquent, provided notice is sent within the twenty-one days' limit, and hence the difficulties of defence are seriously increased. In France the matter has attained very serious proportions, so much so that the Automobile Club de France is preparing a petition to present to President Loubet at the Salon on the subject of the summoning of motorists by the police after merely taking their numbers and without giving any warning that an offence was to be alleged. The French police have adopted this practice to an extent which has greatly alarmed automobilists, and some of them have been fined, although they were not near the place where the offence was alleged to have taken place.

◆ ◆ ◆

A Typical Road in Honolulu.

◆ ◆ ◆

In the Court.

NOT often do the trials of the Automobile Club bring that organisation into the law courts, but those of 1903 have given the central organisation of automobilism great prominence in the King's Bench Division in this week and last. The facts of the case are fairly simple, and the Lord Chief Justice seems to have ruled that the jury had mainly to consider the question of damages suffered by Mr. Weigel and the British Automobile Commercial Syndicate by the refusal of the Club to allow the former to compete in the Reliability Trial from the Crystal Palace last year. The facts are familiar to all who take an interest in these events. Mr. Weigel ran a Clement car on the first day, but it was decided that he should not be officially started on the second by reason of the fact that he was not on the Club's register of trials. As, however, we understand that the Club have decided to appeal against the decision of the Court of King's Bench, comment on the case must be left till the final settlement.

Electrical Timing.

ELSEWHERE we give the paper that was read at the Automobile Club last week, when the attendance showed a lack of interest that was really surprising Col. H. C. L. Holden was in the chair, and pointed out that all accurate measurements of high velocity were done entirely by electricity—mechanical first and electrical afterwards—but the registration was, as a rule, electrical. There were two ways of registering electrically; one was by spark, which was not very practical, because it was not always possible to make a spark go straight, and therefore it was very difficult to make it mark really definitely and properly. The other method was by moving a lever with a pen on it. There was another system of electrical clocks, whereby it was quite easy to work up to one-thousandth part of a second by means of a balance wheel. The French Club was the first to adopt a system of electrical timing for motor-cars. With regard to the English method, they had taken the precaution to duplicate the records, so that they were practically proof against any breakdowns, unless caused by some unruly person or by a thunderstorm. With present-day racing cars, at the highest speed they travelled six inches in a three-hundredth part of a second, and unless, therefore, they could time them to that degree of accuracy it would not meet their requirements. The Club's system did that, and, further, it gave them the power of checking that record at any time afterwards, both as regarded the time and the point at which the car crossed the line, and these records could be put into the archives of the Club, and, in the case of any foreign competitor saying that the records were incorrect, there were the records which would remain as long as the Club remained.

◆ ◆ ◆

Wisdom on the Bench.

MR. JUSTICE DARLING seems to combine judicial acumen with a layman's levity in summing up matters where motor-cars are concerned. The other day, in the hearing of a case in which a motorist was the defendant, he urged the jury to have no feeling against him because he owned a motor-car. The judge did not know whether any juror possessed such a vehicle; for his own part he did not, nor did he want to. People who had horses disliked motor-cars, not only because of the smell and dust associated with them, but also the "look of the people in the cars." Really this is a point of observation which we had hardly expected from a judge, especially one who has had experience of election methods in Hackney and Deptford ere he assumed a judicial position If Judge Darling commences to criticise the look of the people in the cars he must expect the latter to take notice of the looks of judges on the bench, and the question then to decide will be as to which will have the advantage.

◆ ◆ ◆

Motor-Car Imports and Exports.

THERE was again a falling off in the number of foreign motor-cars imported into this country during the past month, although, on the other hand, a slight increase is shown in the value of the imports. The number of cars imported in October is returned at 282, of a value of £117,296. Parts were responsible for £22,521, bringing up the total for last month to £139,817, as against £120,065 in October, 1903. So far this year, that is to say, for the first ten months, the imports stand at £2,176,978, or approximately £399,000 more than in the same period of last year. Passing now to the exports of British automobile productions, the returns continue somewhat disappointing, only 67 vehicles being shipped last month, these, with the "parts," being valued at £22,275, while for the ten months ending with October the exports are returned at £240,047, or about £2,200 below the total recorded for the corresponding ten months of last year.

AT the Horse and Jockey Hotel, Luton, Mr. H. Burrows has a large yard and inspection pit for motor vehicles.

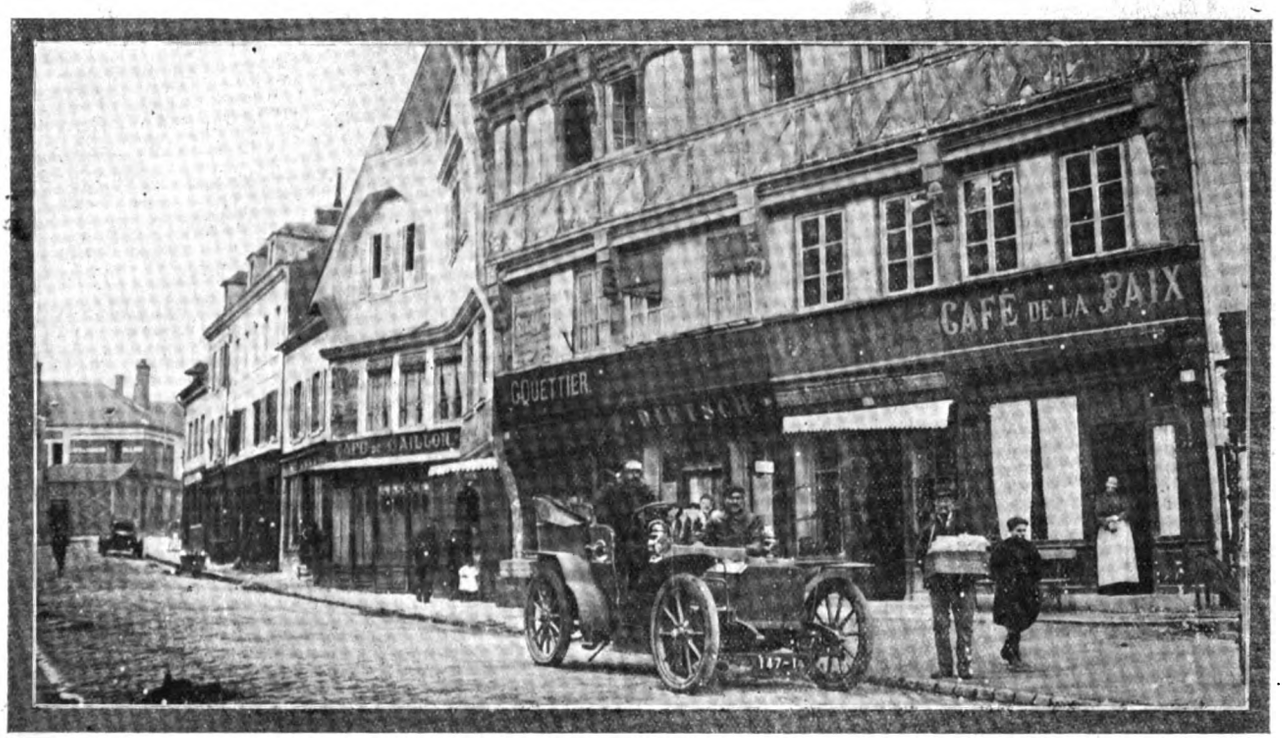
MOTOR-BOATING DOWN RIVER.

[By One of the Party].

NEVER heeding the sailor's prejudice against setting sail on a Friday, Mr. J. W. Stocks, Mr. H. T. Arnott and a small party motored down river from Oxford to Maidenhead on a recent Friday, on board the 6-h.p. single-cylinder thirty foot launch "De Dion."

Old Father Thames lay very dark on the weather bow as, at 5.30 a.m., we cast off from Salter's, started up the engine and headed the "De Dion" down stream.

The reason of the early start was a sporting desire to know what mileage could be covered in a boat of this type in the twelve hours between dawn and dark. The "Admiral" reckoned upon doing a steady six miles an hour, locks included, and we consequently expected to reach Maidenhead by the time 5.30 p.m. chimed.



This reckoning of the "Admiral's," notwithstanding that it had been cast in the prosaic atmosphere of Gt. Marlborough-street, proved that theory and practice may on occasion go hand in hand, for darkness settled down upon the face of the waters shortly after hazarding the perilous passage through Boulter's Lock, and practically the object of our journey had been accomplished. We had even found time to sample the seductive attractions of "The Lamb" at Wallingford, the "Red Lion" at Henley, and to take out the clutch an appalling number of times on behalf of people in punts, who apparently followed the gentle art without other result than the raising of supercilious smiles among the fish with which the river is alleged to abound. The lock keepers *en route*, under the persuasive summons of a large motor horn, overcame for the moment the state of ineradicable inertia in which they are supposed to exist, and treated us very fairly.

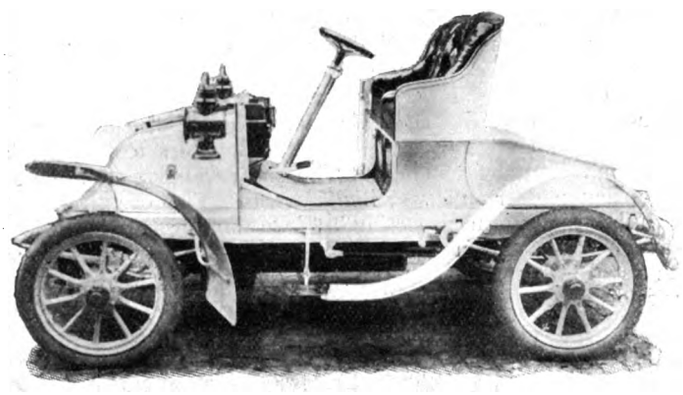
The round of the clock was completed as the Ray Mead Hotel was sighted by the man on the lookout, and this juncture being critical, an immediate adjournment thereto was made, a hurried consultation held, and a resolution passed to temporarily abandon the good ship "De Dion" and conclude the journey to town by rail.

According to the "Admiral's" charts, dead reckoning and log, to say nothing of a very serviceable guide book containing tabulated distances from lock to lock, we had completed exactly 62 miles 1 furlong 6 yards, and had occupied just one round of the clock in so doing. Of course we at no time harboured even the slightest intention of exceeding the legal speed limit had there been one about, and as we waited the convenience of the G.W.R. in a comfortable smoking room we were able to scrutinise the reports handed in by the various officers who had been on duty throughout the day with a calm consideration born of clear consciences.

The Navigating Lieutenant reported that, despite the unusually large number of fishing craft encountered upon the banks and shoals of the upper reaches of the river, he had not found it necessary in a single instance to order the Senior Ordnance Officer to discharge his gun. The Chief Engineer for his part had absolutely no mechanical troubles to bewail, the motor having upheld its reputation for reliability in the most exemplary manner on a very limited consumption of petrol.

The Purser, in reporting a clean bill of health, made a gratifying announcement that the chief steward had not yet exhausted his supplies, and the Admiral, with so satisfactory a series of reports before him, was pleased to bestow a well-merited word of commendation here and there, and to defray the expense of conveying passenger, officers, and crew to the railway station in a single horse motor and wagonette.

A Street in Gaillon—a typical old-world town in France.



The Kelsall and Lostock Graham (Cheshire) parish councils have asked the County Council to apply for a reduction of the legal speed limit of motor-cars passing through their areas.

Thery, with his 1904 Gordon Bennett Richard-Brasier racer, Paul Sartori, with a 90-h.p. Fiat, Bernin, with a 60-h.p. Renault, and Barney Oldfield, with the Peerless "Green Dragon," came together in a ten-mile race at the Empire City track Yonkers, U.S.A., on the 29th ult. The event was run off in three heats, two preliminaries and a final, with two cars in each heat. In the first heat Sartori and Thery were competitors. The latter lost ground at the turns, Sartori steadily increasing his lead and finishing nearly a quarter of a mile ahead. His time for the ten miles was 9 min. 45 4-5 sec. Oldfield won the second heat against Bernin, his time being 9 min. 20 sec. In the final between Sartori and Oldfield the latter won by half a lap, finishing in 9 min. 12 3-5 sec

THE PROSPER-LAMBERT 8-H.P. CAR.

A CAR which attracted much attention in the recent Small Car Trials was the 8-h.p. Prosper-Lambert, introduced into this country by the Holland Park Motor Company, and of which an illustration is given herewith. The frame is of channel steel construction. The motor is of the single-cylinder type, 110 mm. diameter by 120 mm. bore, and, although

rated at 8-h.p., is stated to develop 10-b.h.p. at a speed of 1,300 revolutions per minute. An automatic governor acts on a throttle valve, which is also controlled by a throttle lever on the steering column. A float feed carburettor furnishes the mixture, and the electric ignition is by means of accumulators and high-tension coil. For cooling purposes a water tank is fixed to the dashboard under the bonnet, the circulation being maintained by a centrifugal pump attached to the *chassis*, and driven direct by the engine shaft. The clutch is mounted on ball-bearings and is arranged to give a gradual engagement and to be easily adjusted. Three forward speeds and reverse are obtainable by the provision of a sliding gear enclosed in an aluminium box. The power is transmitted by means of a universally-jointed shaft and bevel pinions to the rear live axle. The latter has large ball-bearings to take up all strains on the bevel pinion. The cups are easily adjusted, and the wheel hub bearings have double rows of balls in grooved cups, with rings of hardened steel. The small bevel pinion on the end of the cardan shaft is also mounted on adjustable ball-bearings. A pedal-operated metal to metal brake is mounted on the driving shaft, while a hand lever actuates internal expanding brakes connected with the hubs of the rear road wheels. The weight of the car is about 12 cwt., while the leading dimensions are, length 9 ft. 4 in. and width 4 ft. 10 in. The car is supplied either as a two-seater, as illustrated, or can be furnished with a tonneau in place of the sloping tool box at the rear.

THE American mail this week brings the news that the Winton Motor Carriage Company, which has hitherto pinned its faith to the horizontal engine, announces the introduction of cars with four-cylinder vertical motors for the 1905 season. Three sizes will be made, 18-h.p., 30-h.p. and 40-h.p.

MESSRS. W. WATSON AND CO., of Liverpool, have, we learn, been appointed British agents for the Berliet petrol cars, of which they intend to keep a stock of spare parts. The vehicles, which are made at Lyons, are built on Mercedes lines, ball bearings being used throughout, including those in the gear box.

A WINNIPEG correspondent writes that in Western Canada, where the thermometer often falls forty degrees below zero, the question of a non-freezing solution for use in the water-circulating system is agitating the minds of motorists. It is, however, hoped that the difficulty will be overcome by the use of a new compound, which Professor Kenrick, the Government Analyst, and secretary of the Winnipeg Automobile Club, has prepared. The formula for the preparation is at present a secret, but it is stated to have stood numerous tests made at 40 degrees below zero without showing any signs of freezing.

CONTINENTAL NOTES.

The Gordon Bennett Race.

At a meeting of the sporting committee of the French Automobile Club last week the various suggested courses for next year's Gordon Bennett race were considered. It was resolved that ere arriving at a decision the various courses should be closely inspected by a sub-committee.

◆ ◆ ◆

The Vincenzo-Florio Cup.

The rules governing the International Cup, presented by M. Florio, a well-known Italian motorist, have just been issued. Cars of less than 1,000 kilogs. are eligible for entry, and, except in certain particulars, the race will be run under the same rules as the Gordon Bennett cup race. The cup will be competed for seven years consecutively, the manufacturer whose cars win the most times finally securing the cup, a tie requiring a further race to decide the final owner. The race must always be run in Italy over a distance of 800 to 1,000 kiloms. The entry fee is £10 per car; the number of entries is not limited, so that any maker wishing to enter a car may do so. The first race will probably be held in August, 1905, on a circuit in the Brescia district.

◆ ◆ ◆

Changes in the French Trade.

The "Automobile" announces that M. Georges Richard has retired from the motor car company which bears his name, and is about to start a new factory on his own account. From another source we learn that he has formed a company with a capital of £16,000 to construct a new type of car to be known as the "Ajax."

◆ ◆ ◆

Record Breaking at Ostend.

During the past week the Darracq Company have been subjecting several of their cars to record breaking attempts on the Nieuport-Snaeskerke road, near Ostend. Hemery, with a light racer, made several attempts at the flying kilometre. In the first his time was 26 sec., the second run he achieved in 25 1-5 sec., equal to over 89 miles per hour, falling back to 25 4-5 sec. in the third attempt. The previous record for this class of car was 26 1-5 sec., and was held by Hanriot on a Clement-Bayard. On Saturday last, on the same road, he succeeded in setting up new figures for the standing mile, covering the distance in 51 2-5 sec.

◆ ◆ ◆

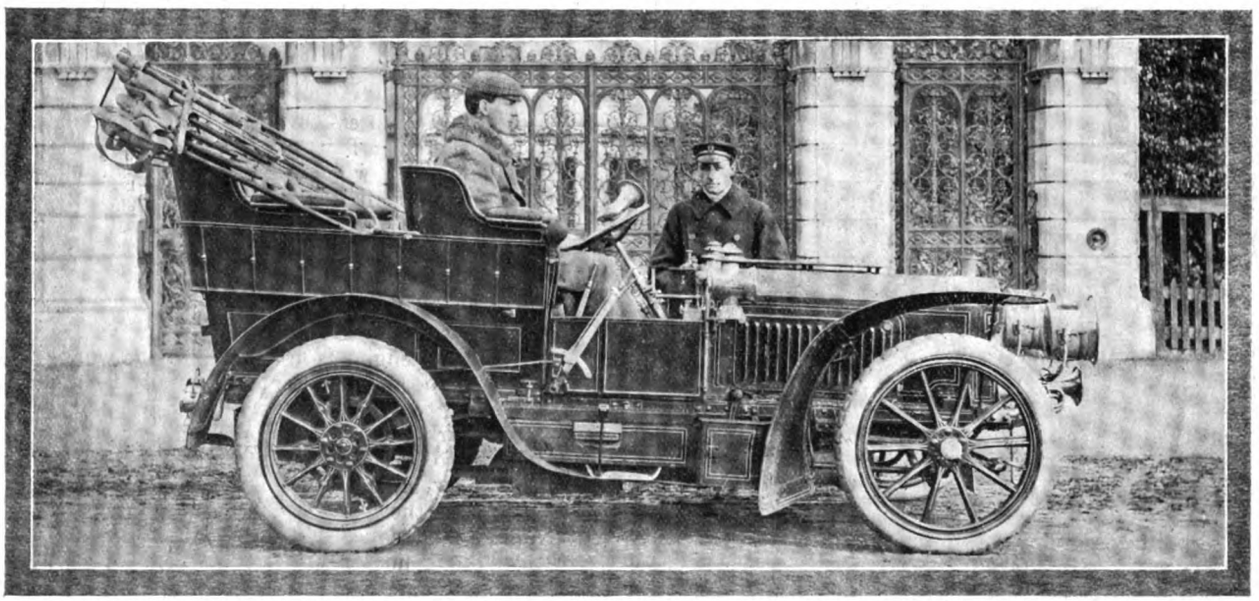
Foreign Attaches at the French Military Manœuvres.

Digitized by Google

A New World's Record.

Baras, with his 100-h.p. Darracq, has also been record-breaking at Ostend, covering the flying kilometre on Sunday last in 21 2-5 sec., 1-5 sec. better than the previous best, held by Rigolly. The speed attained is equal to over 104 miles an hour. The Darracq cars now hold the world's records for the standing mile and the flying kilometre for each of the three classes—voiturettes, light racers, and heavy cars.

◆ ◆ ◆



Motor-Boating on Lake Geneva.

The municipal authorities of Evian are arranging to hold a motor-boat race meeting on Lake Geneva on September 1, 1905. The programme will include events for cruisers and racers.

◆ ◆ ◆

A Motor-Car Body Competition.

The latest competition to be organised in Paris is one for motor-car bodies. The rules are not yet fixed, but it is understood that the vehicles are to be divided into classes according to price. The idea of the trial is not so much for carriage builders to enter specially-made vehicles as for private owners to enter their cars.

Mr. Basil Johnson at the wheel of the 20-h.p. Napier he will drive in the Delhi-Bombay Reliability Trial.

Automobilism in Russia.

That steady progress is being made by the automobile movement in Russia may be judged from the fact that 657 motor-cars and cycles have been duly licensed in St. Petersburg. A new regulation with regard to automobile traffic in Russia is at present under consideration. It provides for a speed limit of 12 versts per hour in towns, the affixing of a number plate, and a tax of three roubles per horse-power of the car. The Russian Automobile Club has protested against the proposed regulations, urging that a speed of 20 versts should be permitted, and that the tax on cars of 15-h.p. and over should be 20 roubles, and one rouble per horse-power for cars under 15-h.p.

◆ ◆ ◆

Motor-Cycle Touring.

The example set by the De Dion-Bouton Company in sending Cormier on a long tour on the new 15-h.p. De Dion car is now being followed by makers of motor-cycles. From Paris early last week M. Baron set out on a 3,000-kilometre tour round France on a 3-h.p. Bailleul motor-bicycle, while on Wednesday of this week Osmont, who was a prominent rider of the motor-tricycle a few years ago, left the A.C.F. club house in Paris on a more ambitious tour. His mount is one of the 1905 F.N. motor-bicycles, and on it he is visiting all the leading towns in France. After reaching Nice, his route is Turin, Milan, Lucerne, Basle, Baden, Mayence, Cologne, Amsterdam, Antwerp, Brussels, and back to Paris. The test is therefore a varied one, and if successfully accomplished will give the machine an excellent send-off in the motor-cycling world.

◆ ◆ ◆

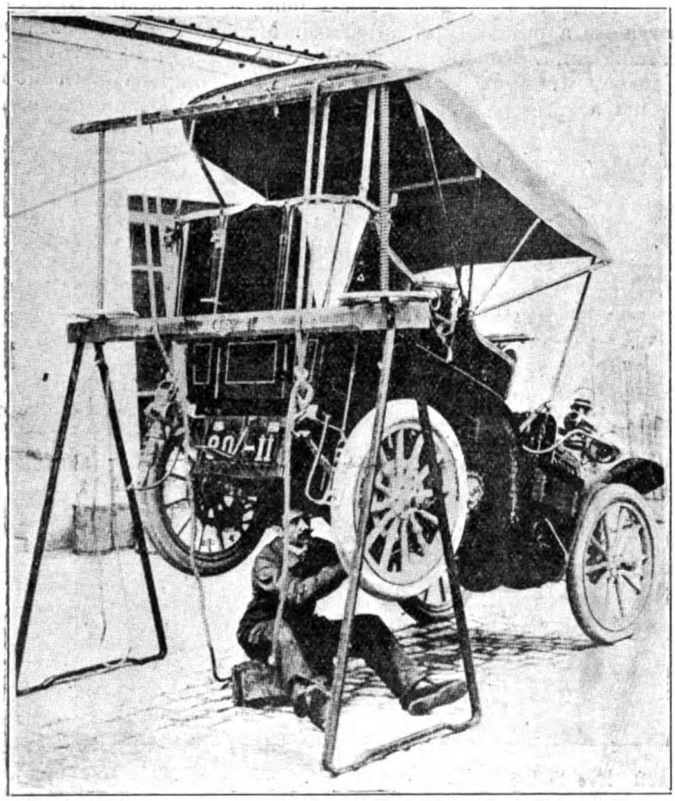
Motor-Boating at Monaco and Cannes.

The International Sporting Club of Monaco is organising a big motor-boat meeting at that Mediterranean resort for the 1905 season. The Grand Marine championship race, over a distance of 125 miles, will be open to motor-boats of every description. The meeting will be held in April next. Arrangements are also in hand for a number of motor-boat races at Cannes, to follow the Nice automobile week. Mr. Alexander Burton has just offered a special cup to the Cannes Automobile Club for competition between boats entered in the racer category.

◆ ◆ ◆

Public Services in France.

It is announced that a Grenoble syndicate proposes to organise a public service between Moutiers, Salins, Bozel, and Pralognan, at the foot of the Vanoise Glacier, in Savoy. The journey would be made in two hours, as compared with the five hours at present taken by horse-drawn vehicles. Commencing with the new year, a service is also to be started between Tarbes and Trie (Hauts Pyrénées); it is intended for the transport of both passengers and mails, and is subsidised by the Conseil General of the Department.



THE Ace Motor Syndicate, Limited, has been registered with a capital of £5,000 to acquire the business of Messrs. F. C. Meyer and L. S. Bidwell, hitherto carried on by them at Hammersmith Road and elsewhere. Mr. F. C. Meyer is the first managing director and Mr. L. S. Bidwell the first technical director. The registered office is at 122, Hammersmith Road, W.

MR. T. H. HOLDING, the well-known motorists' tailor, has had the misfortune to break one of his legs. The accident happened when he was passing through Ripley on his motor-cycle, and occurred through a cart closing in on the near side of the road and not allowing sufficient room for the motor-cyclist to pass through. The driver of the cart, instead of retaining his position, closed in, and it was in avoiding the horse that the motor-cycle just grazed a standing vehicle which was being passed on the right side. This caused the machine to rebound against the wall and the other cart. The consequence was that it was thrown over, the machine falling on the left leg of the rider.

Digitized by Google

A MOTOR-CAR SUPPORTING TRESTLE.

A FRENCH firm, M. Henri Edeline, of Paris, has recently introduced a car-lifting device which should prove a useful substitute for inspection pits, not only in large motor-repairing establishments but in the private garages of many motorists. As will be seen, it consists of a stand about 5ft. 9in. high and 6 ft. 6 in. wide. Parallel with and above the crosspiece is a second cross bar having long screw-threaded legs. The latter pass through corresponding holes in the cross piece, and by means of the two hand wheels can be raised or lowered at will. Stout ropes with hooks are provided, and by passing these over the crossbars and securing the ends to the dumb-irons, either end of a motor-car can be raised, by means of the hand wheels, from the ground, as shown in the illustration, enabling

the various parts to be got at without it being necessary to lie on one's back, never a comfortable position in which to effect adjustments at the best of times. There is no danger of the car being accidentally let down, as it requires force to turn the hand wheels downwards as well as to raise the car. The whole car can be raised bodily, if desired, by means of two such trestles, one in front and one at the rear, enabling a vehicle which is not to be used for some time to have its weight taken off the tyres. The apparatus appears to possess advantages over the pit in that the latter usually necessitates the use of artificial light, while the trestle may be used on the shop floor or in the yard, while its relatively light weight enables it to be readily taken to breakdowns on the road. It is made in various sizes, suitable for supporting cars weighing from 10 cwt. to 2 tons.

FROM Messrs. J. I. Thornycroft and Company, Limited, comes a copy of an extensive new catalogue of Thornycroft steam wagons they have lately issued. The list, which extends to over 100 pages, gives full particulars of the standard four-ton vehicles, five ton wagons, municipal vehicles, and the colonial type, a number of full page illustrations of each being included, rendering it a useful book of reference to all intending users of heavy motor vehicles.

SOME USEFUL NOTES.

IT must never be forgotten that, even for two engines of identical size and make, there exists no arbitrary standard of the amount of lubrication required. This depends essentially upon two factors: (1) the work performed by the engine, and (2) the efficiency of cooling. With regard to the first factor, generally speaking, less oil is required on a smooth, level, dry road than on a rough, hilly one, this being dependent on the fact that less mixture is used, less heat is generated, and less oil, therefore, consumed in the former than in the latter case. But the variation required is never great.

◆ ◆ ◆

THE aspect of the subject from the point of view of the efficiency of cooling is especially important to motor-cyclists, who mostly use air-cooled engines, and to drivers of engines cooled on the thermo-syphon system ("natural" or gravity circulation). Air-cooled engines which are in a favourable position for cooling use up far less oil than those less fortunately placed. Again, taking two engines of identical make and size, one cooled by pump, the other by natural circulation, the former, according to the writer's experiments, will require just double the amount of lubricating oil of the latter.

◆ ◆ ◆

AN important point, and one which is frequently overlooked even by quite experienced *chauffeurs*, is the relationship of lubrication to compression. When an engine is being efficiently lubricated there is a film of oil between the piston, piston-rings, and cylinder wall which makes the joint sufficiently tight to prevent escape of mixture to the under-side of the piston, and so serves to maintain compression. If this film is absent or incontinuous, there will be loss of compression, and since the oil is being continuously used up it must be replaced at the same rate at which it is consumed.

◆ ◆ ◆

WHEN an engine is first tested at the works before the car is delivered to the purchaser it is literally "swamped" with oil, a proceeding to which we owe the discovery of the action of the external spark gap. It is an excellent practice, and one which cannot be too strongly recommended, for the owner of a new car to also swamp his engine with oil until the plug becomes foul, utilising the spark-gap to obtain regular firing. He should then gradually reduce the quantity of oil until a point is reached when the plug no longer becomes foul. The ideal lubrication point for ordinary conditions of work has then been found—that is, the point at which the engine is taking all possible oil without danger of sooty deposit on the valves, piston, or plug. But it must be remembered that, for maximum efficiency, the amount of oil supplied to the engine should vary somewhat, as already stated, in proportion to the work.

◆ ◆ ◆

MOST makers prefer to recommend some particular brand of oil for their engines, and an extended experience has convinced the writer that their advice should always be followed. Never run an engine without oil. If the supply gives out on the road, get any kind that is obtainable; even salad oil will do, in lieu of anything better. Finally, it may be stated that it is better to over than to under lubricate.

◆ ◆ ◆

DURING very cold weather a considerable amount of trouble is caused by frozen carburettors. In many cars the carburettors are jacketed with a branch from the exhaust or from the water-tank, and in such, of course, no trouble is experienced. The symptoms of a freezing carburettor are: (1) Gradually decreasing power in the engine; (2) little or no response when the throttle is opened. Treatment: (1) Hot rags applied to the carburettor; (2) if there is need for haste a few drops of petrol may be poured on the carburettor (the tap between it and petrol supply being closed) and a light applied. Needless to say this method is only applicable where the carburettor is suitably situated, and should not be adopted by the novice. It requires exceedingly careful handling, or the cure may be worse than the disease.

THE DE DION 15-H.P. FOUR-CYLINDER MOTOR.

(*Concluded from page* 762.)

THE ignition is of the high-tension system with non-trembler coil, a single trembler at the contact maker, that is in the primary circuit, being employed to effect the ignition in the four cylinders. Fig. 1 shows details of the contact maker, in which N is the insulated platinum-pointed screw. Contact is established every time that the four-bossed cam C pushes against the oscillating piece F, that is to say, every half-turn of the motor shaft; the tension spring R draws it back immediately in the opposite direction. The tension of this spring can be easily regulated by the nut S, in which the tail of the spring engages (the other end is joined solidly to F).

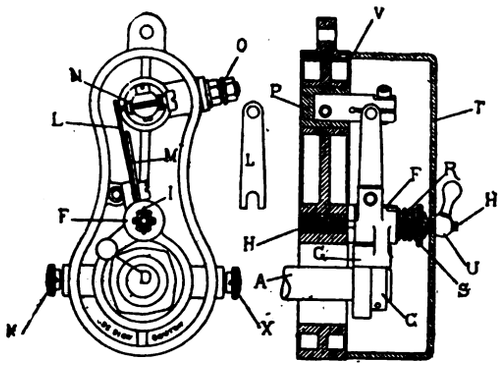

Fig. 1.—Elevation and Section of Contact Maker.

The advantage claimed for the single trembler in the primary circuit is the certainty of synchronous ignition in all four cylinders. The current distributor is arranged in the secondary or high tension circuit. Referring to Fig. 2, on the cam shaft, 2, is fitted a worm wheel, 3, which drives the vertical spindle actuating the oil pump. This spindle, which runs at one-fourth the speed of the crank shaft, supports a porcelain cap, 8, surmounted by the moveable piece of the distributor. The latter comprises a blade, 10, slightly flexible, on which two metal

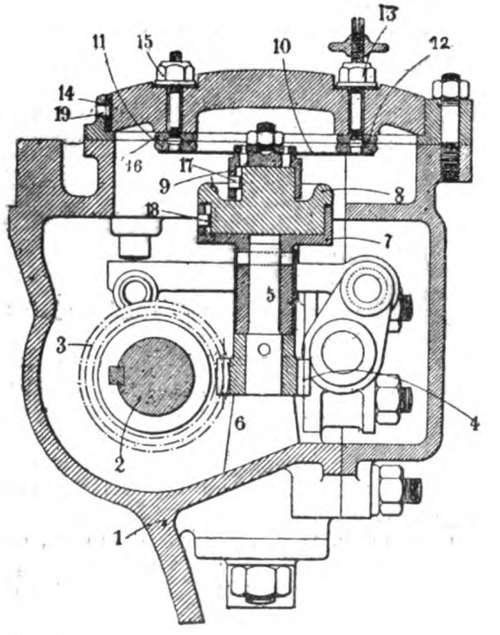

Fig. 2.—Section of Secondary Current Distributor.

stops, 11, are riveted. Each of these stops can touch, during the rotation of the blade, either a fixed sector, 16, connected to the secondary circuit of the coil or one of the contacts which are in circuit with the sparking plugs. The sector, 16, and the terminals, 12, are carried by a porcelain cap, 14, cemented into a cover bolted on to the box containing all the mechanism; metal rods fixed to the sector and to the four contacts pass through the porcelain and are supported at their upper end by terminals to which the wires are fixed. Only one of the terminals, 15, 15, is connected to the coil; the wires going to the sparking plugs start from the terminals, 13, and, to avoid any chance of error, the number of the cylinder to be connected to the terminals is printed on the porcelain itself. The method of operation of the distribution is as follows: the sector, 16, is of such a length that one of the two stops, 11, carried by the blade, 10, is always rubbing against it; the other stop, diametrically opposed to the first, touches successively during the rotary movement of the worm wheel, 4, each of the contacts corresponding to the four cylinders.

A regular distribution is thus obtained, which the working of the advance or retarding of the ignition does not affect, for the contacts have a width and intervals between them suitably calculated with a view to this result. Although the distributor has to fulfil delicate functions with precision, the parts are simple-strong, and not numerous; and it is claimed that the arrange, ment is economical, the trembler absorbing relatively very little

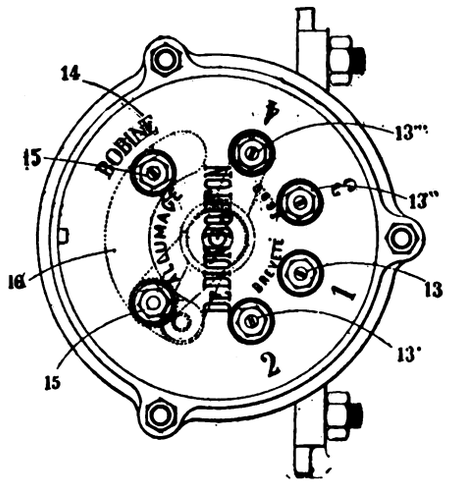

Fig. 3.—Plan View of Secondary Current Distributor.

current. Although rated at 15-h.p., we are informed that the engine is capable of developing 20-h.p., the bore of the cylinder being 90 mm and the stroke 100 mm.

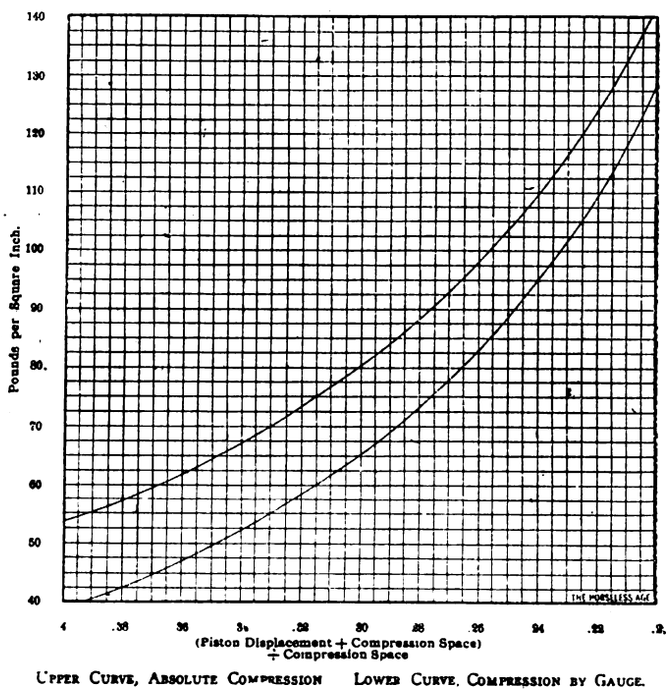
LADY MARGARET STUART has just bought a motor-car, which will be the first automobile on the Island of Bute, an island from which her brother, the Marquis of Bute, not only takes his title, but owns.

THE Prince Hatzfeldt and the Duchess of Westminster have recently acquired Hotchkiss cars from the British Automobile Commercial Syndicate, Ltd., and are now using them at their large shooting parties.

THE Continental Caoutchouc and Guttapercha Co. announce that their motor tyre repair factory at 104-108, Clerkenwell Road, London, E.C., is now ready, and they are in a position to repair covers and tubes in three to four days' time.

THE non-skidders made by M. Beau, of Lyons, and described in a recent issue of the *Journal*, can be obtained from Messrs. A. W. Gamage, Limited, of Holborn. Messrs. Lemaire and Thackthwaite, 289, Oxford Street, W., also keep them in stock.

IN referring to the 1905 Serpollet steam car in our issue on the 5th inst. we referred to the fuel used as being petrol. This was of course a slip, as M. Serpollet has never used petrol—always paraffin. The Speedwell Motor Engineering Co., Ltd., expect to shortly receive one of the new models.



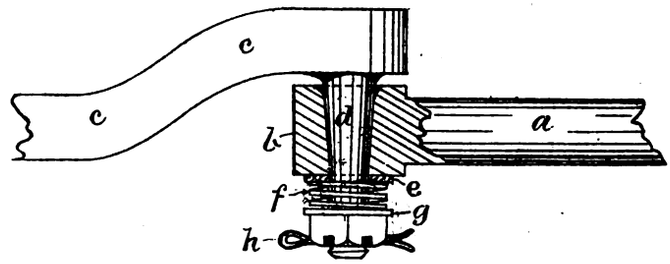
Digitized by Google

COMPRESSION IN PETROL MOTORS.

MANY novices with petrol engines imagine that the compression pressure rises in the same proportion as the volume decreases, and we were somewhat surprised recently to see this rule for finding the compression recommended. Gay Lussac's law, that with a perfect gas, pressure and volume vary in inverse proportions, is often thought to apply to compression in petrol engines, but it does not, as this law only holds for thermostatic compression or compression at constant temperature. When air or gases are compressed there are two distinct causes for the pressure to rise. The reduction of the volume of the gas naturally results in a rise of pressure, but it also causes a heating of the gas, and the heat thus generated produces a further increase in pressure. That is to say, for a given reduction in volume the rise in pressure will be greater if the heat generated by the compression remains within the gases than if some cooling means are employed to keep the compressed gases at a constant temperature. That heating causes the pressure of a gas to rise, if the volume remains constant, is a phenomenon familiar to everyone. The heat, of course, has the same effect if the volume of the gas is changed at the same time that the heat is imparted.

If the compression pressure of the gas varied in inverse proportion to the volume when a certain quantity of gas at atmospheric pressure was reduced to one-half its original volume, the absolute pressure would be 29·4 pounds per square inch; if reduced to one-third its original volume, the pressure would be 44 1 pounds per square inch, and so on. Instead we find that if the volume is reduced to one-half, the pressure rises to practically 40 pounds per square inch; if reduced to one-third, to 69 pounds, and if reduced to one-quarter, to 104 pounds absolute pressure.

The accompanying diagram, taken from the "Horseless Age," permits of easily finding the compression pressure for any proportion of compression space to total volume of piston displacement and compression space employed in practice. The abscissas represent this ratio of compression space to piston displacement plus compression space, and the ordinates represent



UPPER CURVE, ABSOLUTE COMPRESSION LOWER CURVE, COMPRESSION BY GAUGE.

pounds per square inch. The upper curve gives the absolute compression pressure and the lower curve the gauge pressure. For any given compression space the gauge pressure is less than the absolute pressure by the pressure of the atmosphere, 14·7 pounds.

These curves give the compression pressure that would be obtained if the cylinder at the end of the suction stroke was filled with gases at atmospheric pressure and if there was absolutely no leakage from the cylinder and no interchange of heat between the cylinder walls and the charge during the compression stroke. None of these conditions are completely satisfied, and in practice the compression is probably always slightly below that given by the curves.

AN ADJUSTABLE STEERING JOINT.

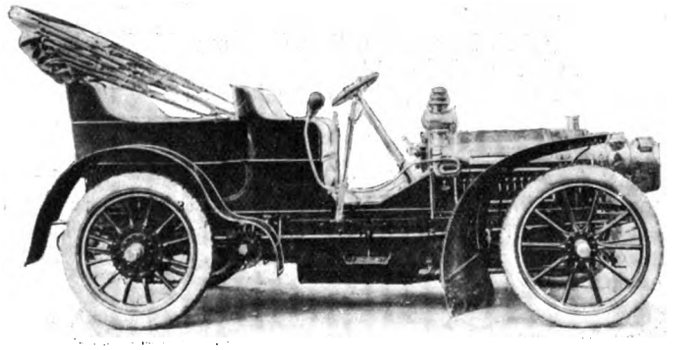
THE accompanying illustration depicts an improved steering joint which has lately been brought to our notice. It is the invention of Mr. A. E. Wynn, of Harrogate, the object being to provide a means of taking up any slackness due to

wear, and also a joint that will not work loose by any vibration or shock to which it may be subjected. One of the pieces or arms *a*, is provided with a socket hole *b*, and the other *c*, with a plug piece *d*; both the hole and the plug piece are formed to one and the same taper, which, however, is not so acute as to cause any risk of the plug binding in the hole. The plug piece is made longer than the hole to allow for wear and to prevent the adjoining faces of the ends of the arms *a* and *c* touching. On the end of the plug is mounted a washer *e* bearing on the end of the socket piece *b* where the hole is narrowest, a spiral spring *f*, and a nut *g*, on the extreme end, which is screw threaded to receive the same, by means of which the compression of the spring can be adjusted. By means of a spring pin or cotter passed through the nut and through the extension the nut can be fixed in the position to which it has been adjusted. Mr. Wynn informs us that he has had the joint in use on the ends of the cross rod of the steering gear which connects the front wheels for about two years, and that they are still as tight and free from play as ever.

MESSRS. CARLESS, CAPEL, AND LEONARD have reduced the price of their standard petrol one penny per gallon.

AT a meeting of the Industrial Storage Battery Syndicate Limited, the chairman has stated that during the past few weeks small carriages had been driven sixty-five miles with a single charge in less than two hours, and a large brougham and other vehicles had been driven forty-five miles without recharging, a new battery made by the company having been employed in each case.

AS an example of the use to which a motor-car can be put in the pursuit of business, Mr. J. H. Lee, manager to Messrs. Rowland Hill, of Coventry, informs us that on the afternoon of a recent Wednesday he left Coventry on a 15-h.p. Duryea for a business journey in the North of England. Travelling *via* Lutterworth to Leicester, he visited a customer in that town, and successively called on others in Nottingham, Beeston, Lincoln, Saxilby, Gainsborough, Goole, Pontefract, Leeds, Halifax, Manchester, and Rochdale, and, returning via Altrincham, Whitchurch and Cannock, was back again in Coventry on Sunday evening, covering altogether some 450 miles. Such a journey could not possibly have been accomplished with a horse-drawn vehicle, and we question very much whether, in view of the difficulty of making railway connections and working in with time tables, the work could have been accomplished by any other means than by a motor vehicle.



Digitized by Google

HERE AND THERE.

A MOTOR-CYCLE club has just been formed at Cannes, France.

MESSRS. J. E. HUTTON, LIMITED, have just brought out a new 10-h.p. four-cylinder gear driven car.

THE Earl of Radnor has lately acquired a Wolseley 12-h.p. Berkeley wagonette.

The above illustration depicts one of the latest Crossley cars, fitted with a detachable tonneau body. As a two-seater the car has a racy aspect and is both speedy and silent.

ASTER, Limited, have been awarded a gold medal at the St. Louis Exhibition for their exhibit of motor-engines.

DAVOS-PLATZ, the great Swiss health resort, is to be provided with a motor-car service connecting it with the town of Davos.

MESSRS. E. KALKER AND COMPANY, insulated wire dealers, have removed to larger premises at 141, Much Park Street, Coventry.

MESSRS. FRISWELL, LIMITED, have supplied Messrs. Clark, Nicholls and Coombs with a motor-van for the conveyance of their confectionery.

THE Highways Committee of the L.C.C. are recommending the purchase of two motor-vans for the further equipment of their tramways department.

LORD DUDLEY, who is an enthusiastic motorist, last week underwent the examination of the Association Generale Automobile in Paris to qualify for a French driving certificate.

A COMMITTEE of the Ripon Rural District Council is inquiring into the width of roads in their locality, with a view to making suggestions as to motor-car traffic to the County Council.

WE learn that the rights in the non-puncturable tyre devised by Mr. H. Meadows, and briefly described in the *Journal* on October 8th last, have been acquired by the Croxted Motor and Engineering Works, Herne Hill, S.E.

IT was stated at the Cheshire County Council's last meeting that there were now registered in the county 327 motor-cars, 315 motor-cycles, 893 licences to drive cars, and 148 to drive motor-cycles, the receipts from these being £724 5s.

THE Traction Corporation, Limited, has been registered with a capital of £100 to acquire any patents and rights relating to the production, treatment, storage, and use of any motive or mechanical power and any apparatus therefor.

THE Pfluger Accumulator Works have decided to establish a factory at Much Park Street, Coventry. They have also acquired commodious offices at Albany Buildings, 39, Victoria Street, Westminster, S.W., for the use of their engineering department.

THE Britannia Motor Garage, Limited, High Street, Marylebone, W., have, we learn, been appointed London agents for the Horbick cars of Messrs. Horsfall and Bickham. A new model of the Horbick Minor for the 1905 season is a 9-12 h-p. three-cylinder vehicle.

MR. F. B. WILKINSON, of Cavendish Lodge, Edwinstowe, near Newark, has adopted an agricultural motor. He ploughed eight acres the other day at a cost of 16s. for petrol and labour. Had he ploughed with a pair of horses, it would have taken eight days at a cost of £4.

THE Erster Badische Automobile Club has just been formed at Carlsruhe.

EXTENSIONS of the motor-'bus service at Hastings to Ore, Silverhill, and Hollington are in contemplation.

GREAT damage has been done by fire to Messrs. Connah and Company's garage and motor works at Rhyl.

THE A.C.G.B I. have appointed a Touring Committee to give information to members wishing for information on tours, etc.

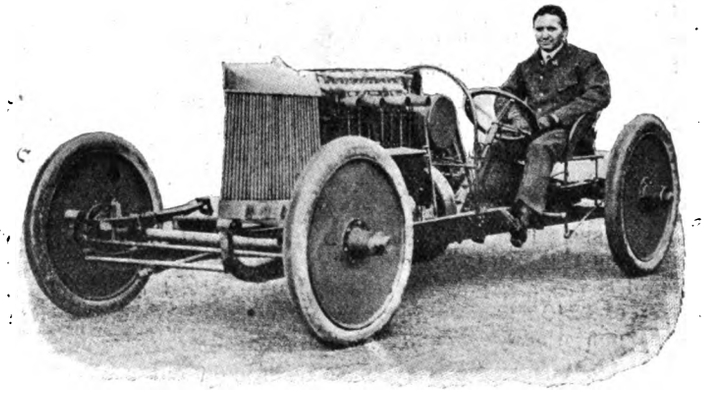
AN inquiry is to be held at Leigh (Lancashire) into an application for restricting the speed of motor-cars in the borough to ten miles an hour.

THE Tasmanian Motor Transport Company has been registered at Hobart. Steam vehicles are to be put upon the road by the company.

TWO 6-h.p. Wolseley cars were recently despatched to Buenos Ayres, Argentina, to the order of La Capital Traction and Electric Company.

THE prizes won by members of the Hull Automobile Club on the recent non-stop run were awarded at the club's smoking concert on the 17th inst.

AMONG the foreign visitors to Blackpool was M. J. Hautier, of Paris, who drove a new 20-h.p. Hautier car from Newhaven to the popular Lancashire resort.



IT will be remembered that a few months ago her Serene Highness Princess Said Toussoun purchased a Baby Peugeot. She has now acquired a 25-h.p. Peugeot, which she drives herself.

THE exports of automobiles and parts from the United States during September last amounted to £24,696, bringing up the total for the first nine months of the year to £289,197, as contrasted with £238,565 in the corresponding period of 1903.

CONSIDERABLE interest is being shown in the forthcoming Delhi-Bombay reliability trial. The entries of British cars so far include a 20-h.p. Thornycroft and a 20-h.p. Napier. The latter, of which an illustration is given on page 777, will be driven by Mr. Basil Johnson.

THE Rossleigh Motor Company, of Edinburgh and Glasgow, have been appointed sole agents for Peugeot cars for these two cities. They have now in stock ready for immediate delivery the new 1905 landaulettes, and the new 10-12-h.p. carriages, besides the standard pattern Baby Peugeot.

A LIMITED liability company has been registered with a capital of £30,000 to acquire and carry on the business of the Duryea Company, Widdrington Road, Coventry. Mr. Henry Sturmey will be chairman. Mr. H. H. F. Hyndman, another of the directors, is a well-known electrical engineer.

Barney Oldfield at the wheel of the new "Green Dragon" racer, built by the Peerless Motor-Car Company.

The car, which is rated at 50 h.p., has a four-cylinder engine, the cylinders being cast in one piece, with one copper water-jacket surrounding them. All valves are in the cylinder-heads, and mechanically operated in order to enable a free exhaust and free intake of gas. The frame is of a new type, and hung below the axles, which gives the lowest centre of gravity possible. The cooler is pointed in shape, so as to reduce the wind resistance to a minimum. The wheel base of the car is 9 feet 8 inches, and the tread 4 feet 8 inches. The car weighs 1,730 pounds; it won a ten mile track race at Cleveland recently in 9 min. 17 1-5 sec.

AT the Tudor Works, Daventry, Messrs. Reynolds Bros. have opened a garage fitted with an inspection pit. They can also undertake the re-charging of accumulators.

Digitized by Google

Two motor-vans have collided on Kingston Hill. The drivers, jumping from their vehicles, escaped serious injury.

To carry on the business of motor-car manufacturers, Messrs. Crawshay-Williams, Limited, have been registered with a capital of £6,000.

MESSRS. H. W. VAN RADEN AND CO. are placing on the market a cheap and simplified form of small and compact high-speed trembler coil, suitable for either a motor-cycle or car. It takes very little current and vibrates so fast that immediately the contact is made a spark is obtained at the sparking plug. The trembler works at such a speed that it is not necessary to use a wipe-spark contact breaker, an ordinary breaker with a point contact for non-trembler coil allowing sufficient current to pass to serve the coil and give several vibrations.

A NEW motor-'bus service has been started at Worthing, the mayor and other prominent local men taking part in the inaugural proceedings.

THE Farman Automobile Co. have been appointed London and district agents for the engines and cars of the Coronet Motor Co., Limited, Coventry.

THE Worshipful Company of Coachmakers and Harness Makers are offering prizes for a design for a motor-car to carry four persons, including the driver.

MESSRS. DIXON BROS. AND HUTCHINSON have established motor-car and motor-boat works at Woolston, on the Itchen, near Southampton, where they will be able to undertake all kinds of repair work.

THE Doherty Motor Accessories Company, Limited, have removed to large and commodious premises in Earl Street, Coventry. The factory is newly built and equipped with all the latest appliances for the manufacture of bonnets, radiators, &c.

THE Caledonian Motor Car and Cycle Company, Ltd., have sold their cycle department, and are concentrating efforts on their motor branch at Bon-Accord Street, Aberdeen. A dividend of 5 per cent. on the capital of the company has just been declared.

THE King and Queen of Portugal, who are at present on a visit to this country, are both keenly interested in motoring, evidence of which is shown in the fact that at an automobile gymkhana recently held at Lisbon both were present, His Majesty acting as one of the judges.

FOLLOWING close upon the opening of a branch in Manchester, 283, Deansgate, the "Otto-Bennett" Motor Company have acquired premises at 24, Rue Brunel, Paris, which are being equipped with all the necessary appliances for vulcanising and fitting "Otto" detachable bands.

MESSRS. FRISWELL, LIMITED, have just supplied the Edmonton Union with a motor-'bus for the purpose of conveying imbeciles. The Edmonton Union assume that there will be a saving of £240 per annum by discontinuing the present system and running the motor-car.

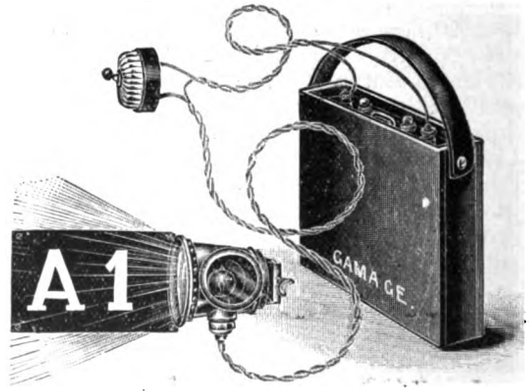
MESSRS. HOLDING AND SON have brought out several new motor garments for the current winter season, including the Westmeath ulster, which is made in four colours, and is cut for either motor driving or ordinary travelling. Their new list also contains illustrations of their standard garments which have long been familiar to motorists.

FROM Mr. F. Bennett, of Sherborne, comes a "Motor Car Diary," arranged with one week to a page, wherein the motorist can keep a record of his trips, the state of the road, the weather, etc., for a year. A summary is also provided for totalling the mileage, and the volume should prove of utility to all who do much motor touring. Messrs. Simpkin, Marshall and Co. are the London publishers of this excellent diary.

MESSRS. HARPER AND CO. have opened a commodious garage in Canal Street, Wolverhampton. Skilled mechanics are employed to execute repairs, and a stock of petrol and spare parts kept on hand. Being in the centre of the town, this garage is supplying a long-felt want.

THE Imre Engineering Company, Limited, has been registered with a capital of £6,000, to carry on the business of manufacturers of motors and motor vehicles, and accessories for the same, etc., and to adopt an agreement with Messrs. O. F. Viola and I. Viola.

THE Immisch Launch and Boat Company, Limited, has been registered, with a capital of £10,000, to acquire from the Immisch Electric Launch Company, Limited, their electric launches, boats, charging stations, property, etc., and to carry on the business of electrical and mechanical engineers.



AN American motorist of a somewhat sarcastic turn of mind is responsible for the statement that motor-cars are of two kinds —those which are well taken care of, and those which have to take care of themselves. You can always tell which is which as they go along the road, making their respective noises.

ON the 15th ult., Delormier Park, Montreal, was the scene of the first automobile races held under the auspices of the recently-formed Automobile Club of Canada. The track is not banked, and is only a half-mile in circumference. The best time of the day was 8 min. 18 sec. for five miles, made by Mr. L. D. Robertson, on a 16-h.p. Rambler.

"ABSTRACTS of British Patents," relating to cycles, motor-vehicles, and attachments and accessories taken out from January to June of the present year, is a new volume issued by the Cycle Trade Publishing Co., Ltd., and extending to 130 quarto pages. It includes all that has been done in this department during the six months, and should be of great value for reference purposes.

FOLLOWING on the case at the West London Police Court, in which a motorist succeeded in securing a dismissal of a summons against him for furious driving, owing to the silent evidence of the speedometer on his car, comes the news of a similar victory in America. A motorist at Salem, Mass., was charged with having violated the speed law. Several officers swore that the motorist was going much faster than the law permits, but the latter and his companion both testified that the car was running within the legal limit. They were backed up by a Jones speedometer fitted on the vehicle, which at no time showed the rate to be too high. The magistrate thought that the officers must have been mistaken, and that the motorist and his friend were in a better position to judge how fast they were travelling than were the policemen.

OWING to tail lamp troubles, there is a growing tendency to adopt an electric lamp to illuminate the back number plate and to show a red light to the rear. With the view of meeting

the demand, Messrs. Gamage, Limited, have just introduced the neat little set illustrated herewith, consisting of a slow-discharging accumulator, switch, wiring, and lamp.

MR. HERBERT SMITH, of 9, Strand, W.C., and 42, Avenue Mansions, Finchley Road, N.W., has arranged for the sole London agency of the Rexette.

MOTOR CYCLING NEWS.

A FEATURE of German cycle club life has long been the songs in praise of their pastime which are indulged in at the winter meetings, and, indeed, at any festive gatherings of the members; and as the ranks of motor-cyclists have been largely recruited from the vast army of cyclists, it is not surprising that the song of the motor-cycle should now be the order of the day. As the movement is yet young, suitable songs are none too plentiful, and with the view of filling this "much-felt want" the German Motor Cyclists' Union of Stuttgart is offering a series of prizes ranging from £5 to 10s. for the six best songs relating to the pastime of motor-cycling. A committee of experts is being appointed to consider the songs sent in, and it is hoped, as an outcome of the competition, which closes on the 31st December next, to publish a motor-cyclists' song book for circulation among the various motor-cycle clubs in the Fatherland.

◆ ◆ ◆

WE illustrate herewith an arrangement introduced by Messrs. E. G. Young and Co., of Nottingham, to assist in the cooling of the engines of motor-cycles. The silencer is not of the usual type, but takes the form of an enclosed fan driven by the exhaust gases. As the exhaust fan revolves, a second one, mounted on the same spindle, is caused to rotate and discharge a current of cold air on to the radiating ribs of the engine. A shield is also fixed close to the cylinder head, to direct the air on to the latter when

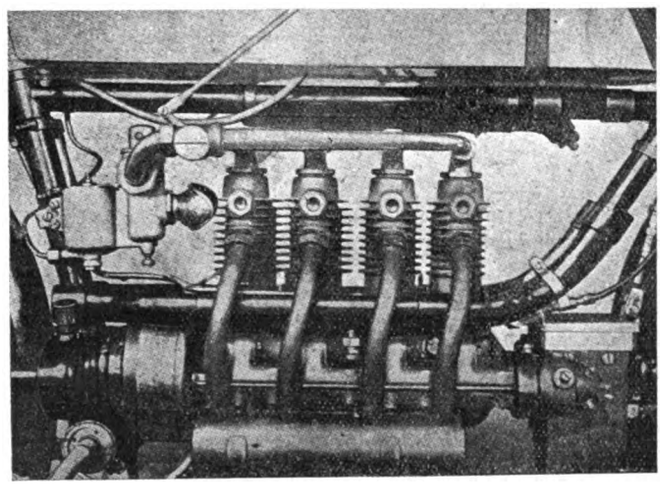
the machine is running. The fans, which run on ball bearings are claimed to be most effective, the one for silencing the exhaust and the other for cooling the engine.

◆ ◆ ◆

A DISTANCE of 7,000 miles has been completed upon a pair of Palmer motor-cycle tyres by Mr. F. T. Heighton with his "Vinco" motor-cycle. This same pair of tyres were used when he competed successfully for the gold medal in the 300 miles reliability trial of the Peterborough and District Motor Club.

◆ ◆ ◆

THE arrangements for the Delhi-Bombay motor trials promoted by the Motor Union of Western India are proceeding satisfactorily. Sufficient entries have been received to warrant a contest for motor-cycles. It has been decided to run this trial in conjunction with that for motor-cars, but the smaller machines will only have to traverse between Agra and Mhow, a distance of 389 miles, to be covered in seven days. The motor-cycles will arrive in Gwalior on the same day as the cars, and will consequently be able to take part in the Motor Gymkhana which will be held by H.H. the Maharajah of Gwalior on December 27th.



◆ ◆ ◆

AT a meeting of the Motor-Cyling Club last week Mr. J. Van Hooydonk read an interesting paper on "The Club Competitions of the past Season, and Suggestions for those of Next Year." The author considered that, however successful the competitions during the past season have been from a general point of view, something better would have to be done in the future to keep the interest of the competitors, judges, and others alive to the vast amount of work that the organising of these events demands, and also to eliminate the element of luck which has hitherto been too great a factor in deciding the competitions. In a 100 miles reliability trial he suggested that those who suffered from punctures should be given a second chance, and that at the end the petrol consumption should be measured. Some test of skill might also be introduced as the deciding factor in the event of a tie as regards the reliability of the machine.

Motor Cycling in India.

Thus a rider might be asked by the judges to remove a certain part of his machine and replace it in the minimum of time, or he might be asked to locate a "fault." In the discussion which ensued, Mr. Candler suggested that for next year a competitive run from Land's End to John o' Groat's should be organised, the distance to be covered in forty-five hours running time, two stops of six hours for rest to be made. Mr. Hooydonk, however, considered 150 miles a day sufficient for any man, and that an excellent competition might be made out of a twenty-four hours'

View of Engine of 1905 F.N. Four-Cylinder Motor Bicycle.

run. Checkers might be stationed every ten miles, the time taken to cover this distance not to exceed 30 min.

WE learn that the Victoria Carriage Works, Limited, of Long Acre, W.C., have been appointed sole agents for the Bollée cars in Great Britain and Ireland.

CORRESPONDENCE.

BRITISH v. FOREIGN CARS.

To the Editor of *The Motor-Car Journal*

Sir,—After reading Mr. Jarrott's letter *re* the position of the English manufacturers, I cannot help remarking that if your correspondent had taken the trouble to inspect some of the foreign-made boats with which the extensive marine victories he mentions had been won, and had compared these boats with the motor-boats that were produced in England last year, he would not have committed the error of stating that the Continental manufacturers were in every way ahead of the British. It was only last week that I came in contact with a beautiful English boat that had just had its engine changed from French to English, because the French motor was entirely unsatisfactory. With regard to the importation of American cars and motors, no doubt, as far as the cheap articles go, the Americans are far ahead of us. They seem to be able to turn out motor-cars which look very pretty, and are very nice for one season of week-end trips. My experience is that this is about their limit.—Yours truly,

S. C. Smee.

To the Editor of *The Motor-Car Journal.*

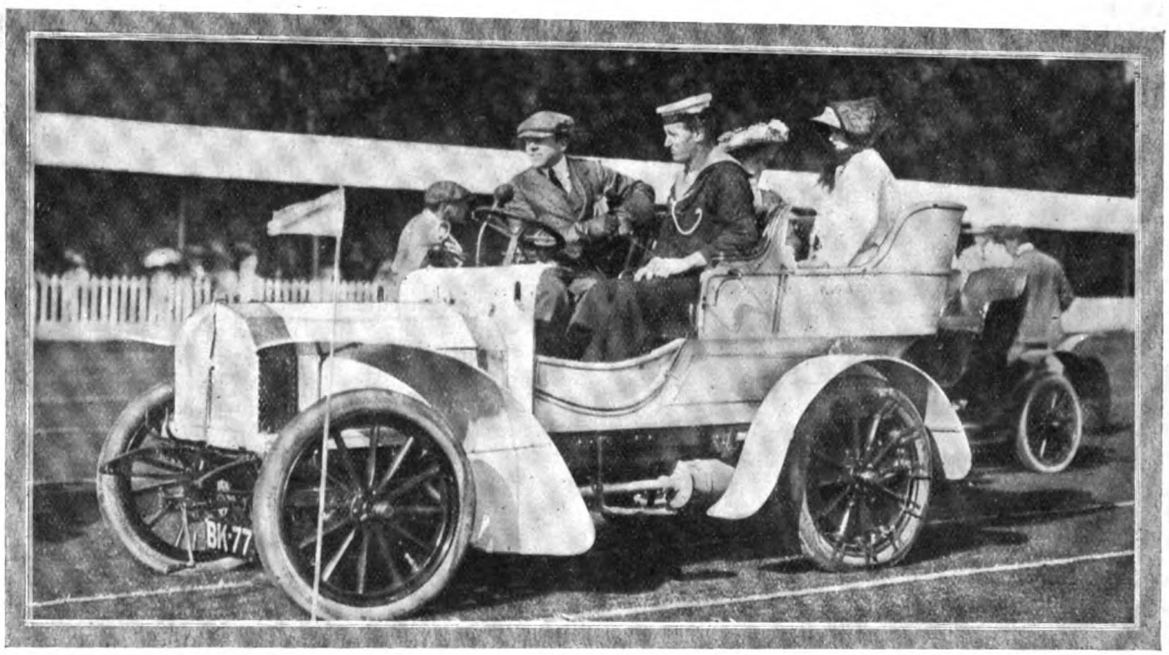
Sir,—As one who has had a varied experience with both British and foreign cars, and who is not interested in the trade in any way, permit me to express my views on this controversy. At present I own a 12-h.p. four cylinder French car, which was purchased early this season and has given little trouble though in almost daily use. Of course I look after it well, do all small repairs myself, and take an intelligent interest in its upkeep. There is not an English-made car of the same class or power that I would to-day exchange it for, and I am certain there is not one obtainable at the price I paid for the car (*i.e.*, when new). I am referring, of course, to English-built cars, not those fitted with French engines and French made throughout with the exception of the carriage work and, perhaps, tyres. An English car of similar make to my own would cost nearly twice as much as my car did, and I doubt whether it would show better workmanship or the number of refinements that my car has. Motorists, *i.e.*, those who know the points of a car, select the French vehicle because it is cheaper and is better value than the English car. I may say I can obtain replacements from Paris from the London agents in a few days, never more than a week. On the other hand, when I owned an English car I sometimes had to wait weeks, even months, for a replacement.—Yours truly,

A. S. Wilson.

To the Editor of *The Motor-Car Journal.*

Sir,—The correspondence which has recently appeared in the *Motor Car Journal* concerning the motor industry seems to me to strike a very vital point, bearing as it does on the future of our nation and British industries in general, and thereby on the future prosperity of the British Empire. Every true British subject should support this comparatively new British industry, which employs thousands of Englishmen, and should feel ashamed to drive in a car of foreign manufacture.

Mr. Jarrott has written pointing out that British motors have not this year won international honours. This is incorrect, and cannot be taken as a proof that they are not as good as those of foreign manufacture, seeing that during the last three years the Napier motors have competed against the productions of all nations and won three international races. Not even Mr. Jarrott can expect British motors to win all the international races every year, but should rather for the present feel satisfied and proud that his country has won so many laurels against such fierce competition.—Your truly,



M. Billingham.

NEWLY METALLED ROADS.

To the Editor of *The Motor-Car Journal.*

Sir—The way stones and new metal are left exposed and unrolled in many places at this time of the year is simply disgraceful, and is a great danger, not only to motor-cars, but to all classes of traffic. A stretch of unrolled metal on a dark night means ruination sometimes to motor tyres, and the practice of lighting up with red lamps a piece of road that is undergoing repair should always be adopted. In particular, I would, with your permission, draw the attention of the road surveyor of Wimbledon to the condition of Gap Road, where, to my knowledge, a big patch of loose stones was left unrolled for at least a fortnight. My first experience of this patch was when driving home from Teddington in the dark one Sunday night recently, the stones being so loose that my little car was actually brought to a stand. A couple of weeks later I came home the same way and found the road in the same rough condition. Not wishing to convert my car into a road-roller, I have since given the road a wide berth, so cannot say if the loose stones are still there, but this letter may serve as a warning to other motorists going that way, and also as a hint to the Wimbledon authorities.—Yours truly,

Claphamite.

Captain Blackett, R.N., on his 12-h.p. Dennis Car. The Misses Fisher, daughters of Admiral Fisher are in the Tonneau.
Photo by [*Stephen Cribb.*

THE USE OF THE ACCELERATOR.

To the Editor of *The Motor-Car Journal.*

Sir,—With reference to the letters by "A. T." and "Foot Control," I certainly am in favour of driving on the accelerator, as it seems to me a much better method than the use of the throttle. The control is solely by the feet, leaving one's hands free for the steering wheel, brake and change speed levers. Its use was favourably impressed on me recently, when I was in one of the new 24-h.p. Fiat cars, and whilst proceeding along the High Street, Southampton, we came dangerously near being wedged between a tram and a heavily-laden dray, and it was only the instant use of the accelerator that enabled us to shoot by one of the posts supporting the overhead wires and between the tram and the dray, well out of harm's way. There is, as "Foot Control" states, the objection to this method of control, in that with the modern four-cylinder engine and automatic carburettor you have such a flexible engine, entirely controlled by the accelerator pedal, that the inability to keep the foot quite steady, more especially on bumpy roads, causes a surging action

Digitized by Google

on the gears, which is minimised where the control is mainly by the positive throttle. But there is a much greater feeling of confidence, by the use of the accelerator, which causes intervention of the governors and the engine speed is varied by the compression and relaxation of the governor spring, more especially when operated by a pedal, which the positive throttle independent of the governors fails to give.

There is no doubt that control will in time be more by the feet, and I for one will be pleased to see this, as, being cognisant of both methods, I am quite convinced of the superiority of that by the accelerator, and were this system more generally adopted, it would do much to reduce the danger and inconvenience of changing cars, which "Simplicity," in his letter under the heading of "The Control Mechanism of Motor-cars," calls attention to.—Yours truly,

R. G. PRIEST.

NON-SLIPPING TREADS.

To the Editor of *The Motor-Car Journal*.

SIR,—In reply to "Norfolk," there is no non-slipping tread that does not to some extent slow a light car. Those of the See or Pullman pattern are better as far as this goes than the Wallwork; I should put their loss at about three miles an hour, when they have become flexible after a few dozen miles' running. Personally I have had the greatest satisfaction from the "Eyre" non-skid, which has no retarding effect, does not injure tyre, and is easily put into and out of action. I have had them on a somewhat heavy 10-h.p. car, that was a bad skidder, since last June, and have never found them fail in their effect. They are, moreover, cheap, especially as regards renewal, and seem to be the only choice at a moderate price where there is no engine-power to spare. They are, of course, not "treads," but I do not think any tread will quite fill the last requirement.—Yours truly,

R. W. BUTTEMER.

To the Editor of *The Motor-Car Journal*.

SIR,—As I see your correspondent "Norfolk" enquires about non-skids for light cars, I should advise him to try the Parsons non-skid device, which I have used on a 10-h.p. single cylinder four-seated car with grand results. They entirely do away with sideslip, and do not slow the car to any appreciable extent.—Yours truly,

B. TURPEY.

A GOOD SUGGESTION.

To the Editor of *The Motor-Car Journal*.

SIR,—Theory has sometimes to yield to practical experience, and it is, therefore, to those who are using motor-cars day in and day out that would-be motorists must look for practical information with regard to motor-cars. A record of the facts and things met with would be very interesting and very helpful to novices if only motorists would take the trouble to make the same public.

It is on the broad plane of imparting useful knowledge that I venture to suggest that owners of motor-cars should write frequently to the *Journal* about the practical points that come up in their several experiences. Some of the things that beginners desire to know about are: (1) The consumption of fuel. (2) The cost of repairs; the kind of repairs most common and the methods taken to carry out the work and prevent recurrence of the trouble. (3) The life of tyres under varying conditions. (4) Useful accessories; that is, all those adjuncts to the car in the shape of lamps, tools, and the like, which are not an actual part of the vehicle. (5) Experiences with various forms of motors, gearing, lubricators, bearings, carburettors, ignition, pumps, etc. (6) General happenings in operation, breakdowns, their causes, results, and repair.—Yours truly,

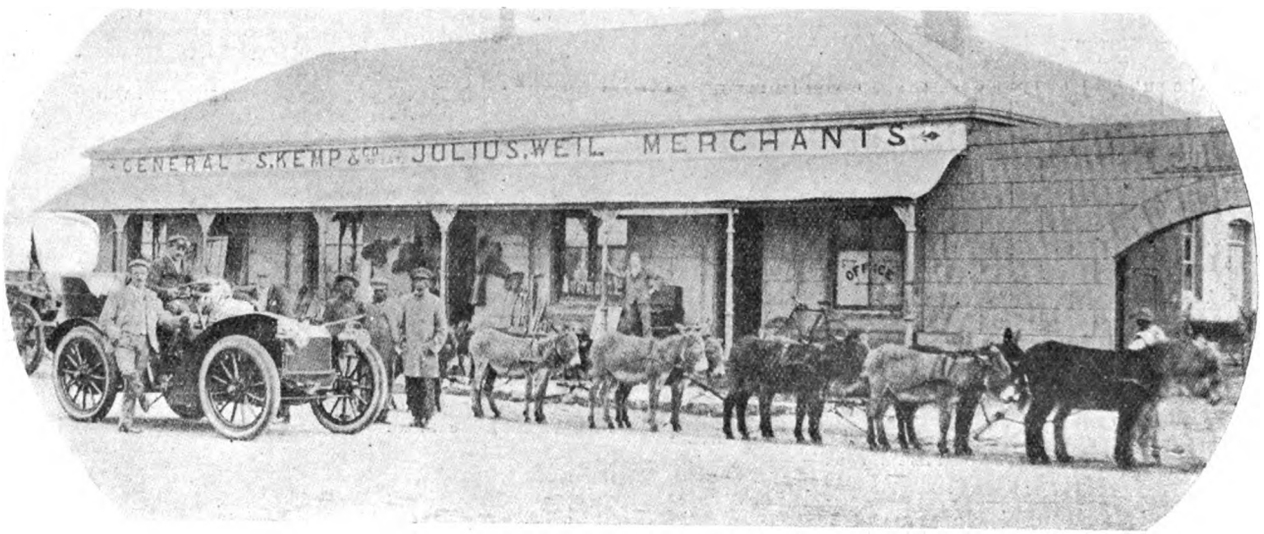
A. FISHER.

WITNESSES OF ACCIDENT.

To the Editor of *The Motor-Car Journal*.

SIR,—If the gentleman who had the misfortune to run over a child at Cricklewood on Saturday afternoon, the 12th inst., should want any witnesses, I should be pleased to give him the addresses of three persons who saw the accident from the top of an omnibus.—Yours truly,

H. R. PARTON.



[Should the motorist interested see this announcement we shall be pleased to put him into communication with Mr. Parton.]

THE CONTROL MECHANISM OF MOTOR-CARS.

To the Editor of *The Motor-Car Journal*.

SIR,—"Simplicity," in his letter in the last issue of the *Journal*, is quite correct in considering that simplicity of control should be the *sine qua non* of all designers and makers of motor-cars. A great improvement in this respect has taken place during recent years, and each fresh batch of motorists finds the problem a less difficult one to solve. Opinions differ, however, as to the direction the efforts to obtain simplicity and at the same time retain efficiency of control should take. Practically all designers are agreed on the desirability of supplying a foot-operated brake, the application of which in some way or other disconnects the engine and the transmission gear. Among drivers it is felt, too, that the brake that is most used as well as most effective should be foot operated; but on some cars the contrary is the case, and the driver, should he be called on to stop suddenly, makes use of a hand lever for the purpose, thus necessitating the removal of one hand from the steering wheel—a practice obviously dangerous at such time. There is likewise a growing feeling that cars should be so constructed that the driver's hands need never be removed from the steering wheel while running, except to make speed changes. The practice of operating the throttle and the sparking advance levers from the wheel is now in fairly general use. It not only permits the driver to keep his hands on the wheel, but avoids the necessity of taking his eyes from the road; for a fleeting glance can be cast at the appliances on the wheel without really losing sight of the road.—Yours truly,

F. BARTON.

The Old and the New at Mafeking, South Africa. [*Automobil Welt.*

ECONOMICAL RUNNING.

To the Editor of *The Motor-Car Journal*.

SIR,—In the *Journal* of November 5th a correspondent refers to the amount of petrol consumed by the 7-h.p. Clyde in the recent small car trials, viz., 47·3 miles per gallon. This does not represent the true capabilities of the car under ordinary conditions. During the ascent of Frome's Hill, the Clyde car (as reported at the time) was run into by a large non-competing car, which bent one of the steering spindles and also the steering gear. The driver made a temporary repair in order to continue the trials, and the car ran to the end with both front wheels running inwards, which consequently acted as a brake. The effect on the tyres was shown at the end by both treads on the front tyres being worn flat. Both before and after the trials, the same car has run from fifty to fifty-three miles per gallon, and this performance is also equalled by other cars of its type. This is accomplished simply through a special

Digitized by Google

means of effecting perfect mixture, and also by arranging the transmission so that friction is reduced to the lowest possible point.—Yours truly,

G. H. WAIT.

THE DEVELOPMENT OF THE TRI-CAR.

To the Editor of *The Motor-Car Journal.*

SIR,—In view of the growing popularity of the tri-car, and the many new machines of this type that have lately been introduced, it is interesting to note what a resemblance these bear to certain vehicles which were apparently before their time. One of these was the Century tandem, and the other was the new Courier "Motoret." The latter was brought out just five years ago by a Wolverhampton concern, and, although almost identical with the modern tri-car, met with but a brief adoption. The machine had a 2¼-h.p. De Dion engine, chain drive, and a clutch, enabling the rider to disconnect the motor at will from the driving mechanism.—Yours truly,

C. W. BAXTER.

CASES AGAINST MOTORISTS.

To the Editor of *The Motor-Car Journal.*

SIR,—On looking through "Cases against Motorists" week by week I am puzzled to know why one man who has had the misfortune to have his rear lamp either jolted or blown out should be fined 5s., whilst another man, hauled up at another police court for precisely the same offence, should be fined 10s., and yet another man at another court be fined £1. In this country we like to boast about the justice we get as Englishmen, and I should like to know why it is possible for a stated offence that varied fines should be imposed.—Yours truly,

JUSTICE.

To the Editor of *The Motor-Car Journal.*

SIR,—*Re* your weekly "Cases Against Motorists," I would respectfully ask you if the publication of same serves any useful purpose. In my opinion you are simply keeping and publishing a record of offences and convictions against motorists, which authorities and others, interested in retarding the automobile industry, may produce as evidence, when the present Motor Car Acts come to be revised at the end of 1905.

I should be glad to know what other readers may think about this subject, and at the same time again express my opinion that such convictions had far better not be published.—Yours truly,

W. F. F.

[The publication of our list is useful as indicating places where official prejudice is still keen against motorists, and also as showing inconsistencies of "justice" throughout the country.]

STEAM CARS.

To the Editor of *The Motor-Car Journal.*

SIR,—I notice in a recent issue the formula of the handicap in the Wolverhampton Club's hill climb was given as follows :—

$$\frac{\text{Time} + \text{H.P.}}{\text{Total weight.}}$$

In some of your contemporaries it is given as :—

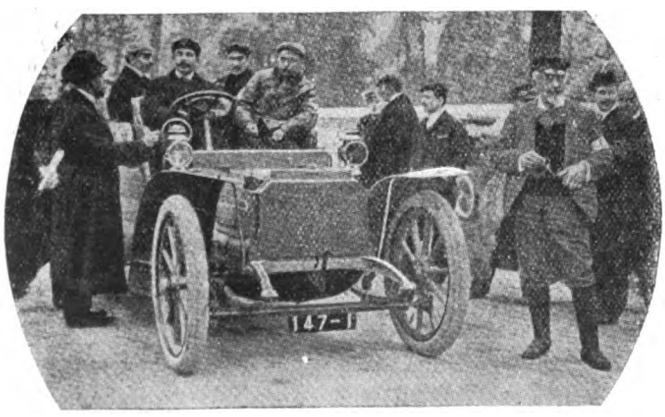
$$\frac{\text{Time} \times \text{H.P.}}{\text{Total weight.}}$$

Now if either of these formula is correct and no excessive handicap was imposed upon the steam cars as compared with petrol cars, the three 10-h.p. "Turner-Miesse" steam cars which ran in the competition would come out first, second and third in the open handicap.

I desire it to be distinctly understood that I do not wish to make it appear that the committee as a body or any individual member thereof have purposely treated the steam cars unfairly.

I can only conclude that a mistake has been made.

I should like to point out, for the benefit of those interested in steam cars, that no particulars were asked from myself or the other drivers of the "Turner-Miesse" steam cars in the competition as to the steam pressure. Every steam engineer knows that it is impossible to rate a steam engine without knowing the steam pressure, but for the benefit of the public I beg leave to quote the following letter receive from Mr. Stephen Watkins, A.M.I.C.E., of Wolverhampton :—



"In reply to your question addressed to me to-day whether it is possible for anyone to rate the actual horse power of a steam engine without knowing the steam pressure which is used, I have to say that it would be impossible to do so."

I am given to understand that the handicapping was in the hands of Mr. F. Straight, of the A.C.G.B.I., and I take the liberty of asking Mr. Straight to inform me :—

1. If there was a penalty on the steam cars ?
2. What was this penalty ?
3. Who fixed the penalty and on what information or grounds ?
4. When was this penalty fixed ?
5. How did Mr. Straight arrive at his estimate of the horse power, when no data was given as to the steam pressure ?

If any particulars were given Mr. Straight as to the steam pressure, will he be good enough to state from whom he received same ?—Yours truly,

J. BURNS DUMBELL.

Cuchelet on the Peugeot Car—the winner of the £600-£720 Class in the Gaillon Hill-Climbing Competition.

To the Editor of *The Motor-Car Journal.*

SIR,—I have just returned from the United States, where I had the pleasure of witnessing the Vanderbilt Cup Race, the first automobile road race of any importance which has ever been held in America.

The action of the Americans in connection with this race in allowing the entry of foreign cars, although such action practically prohibited an American car from winning the cup, stands out in considerable contrast to the action of gentlemen at a race meeting in which steam cars were barred from participation for the sole reason that their speed made them dangerous competitors.

As an American who has resided in England for some years, I must confess to too high an opinion of British sportsmanship to allow an action like this one to take place without dropping a word of warning to the effect that a good reputation for sportsmanship must not only be made, but must be maintained.

During the past year I have been barred from participation in many hill-climbing contests because I drive a steam car. Even in hill-climbing contests in which steam cars were allowed to compete my car was obviously at a disadvantage owing to the rules enforced with regard to standing the car in line for such a time that it would become cold and be compelled to climb under other than ordinary road conditions. In view of this fact I can hardly be blamed for coming to the conclusion that fair play has one definition for petrol car owners and another definition for steam car owners.—Yours truly,

FREDERIC COLEMAN.

TYRES.

To the Editor of *The Motor-Car Journal.*

SIR,—I am about to take up motoring, and propose to use a 10-h.p. car of the Wolseley type. Being undecided as regards tyres, I shall be glad if any of your readers will inform me on the following points :—What is the average mileage life of the following tyres when used with such a car :—(a) Michelin, (b) Palmer Cord, (c) Continental, (d) Dunlop ?

Would anyone also kindly inform me, apart from this, which he thinks would be the best tyre for my purpose, viz., for touring ?

Thanking you in anticipation.—Yours truly,

F. M.

OVERHEATING TROUBLES.

To the Editor of *The Motor-Car Journal.*

SIR,—Referring to Mr. A. E. Coleman's letter in the last issue of the *Journal*, the trouble would appear to me to be owing to the space around the exhaust valve being furred, or there may probably be a faulty cylinder casting. Sometimes in the casting the small cores round the valves become broken, allowing the metal to be solid, hence the overheating Mr. Coleman mentions. The size of the water-pipes should be quite large enough for the engine, and the connections, also, are correct.

With reference to the ignition, this would not make any difference to the overheating of the exhaust valve.—Yours truly,

H. J. S.

JACK FOUND.—Messrs. E. T. C. Morriss and Company, 137a, Finchley Road, N.W., have found a motor-jack near Swiss Cottage Station, which they will be pleased to return to the rightful owner.

GOGGLES FOUND.—Messrs. G. Candler and Sons, 258, Brixton Hill, S.W., have found a pair of goggles on Upper Tulse Hill, which they will be pleased to return to the owner.

ELECTRICAL TIMING APPARATUS.*

By C. W. S. CRAWLEY.

THE ordinary method of timing races is, of course, by stop-watch, and this has drawbacks, for two reasons—the watch and the user. The watch, even a theoretically perfect one, only registers the results to 1-5 second. This is not close enough for a short race. Take a flying kilometre, run in 25 secs., there are only 125 fifths in 25 secs., so that the result is only given correct to 1 part in 125. To look at it in another light; in 1-5 sec. a car travels 8 metres. We measure the course with great accuracy, say, to half a metre or less, and then time it as if 8 metres did not matter. Another way of putting it is that at a speed of 100 miles per hour, 1-5 sec. means a difference of well over half a mile per hour.

Racing against the clock is even worse. Say a watch registers 2 1-5 sec., this merely means that the button was pressed somewhere between 2 1-10 and 2 3-10 sec. Say the car passed really at 2 1-10. The watch at the finish may register 31 1-5 when it should really have been 31 3-10. The real time is 31 3-10—2 1-10=29 1-5, whereas the watch gives it 31 1-5—2 1-5=29, so that its time is given 1-5 too long. The opposite may occur for the next car, so that its time is given 1-5 too short. The two cars may have really run a dead-heat, and yet absolutely perfect stop-watches, absolutely perfectly pressed, may show 2-5 difference in their times. This is the extreme error which can occur; the probable error is only 1-20 sec. The odds against an error of 1-5 in the above case would be, perhaps, 5 to 1, and against anything like 2-5 very much greater, but the uncertainty is always there. You never know, or can find out, than an error of 2-5 has not crept in.

Now, there is another source. Watches are nearly perfect, but not quite. There are watches belonging to Mr. Woollen and Mr. Straight which did not show any difference at the Small Car Trials after eight hours. This is a perfect triumph of watchmaking, regulating, and handling; and we cannot hope for better, I think. But it merely shows that at the end of that time one had not gained quite as much as 1-5 on the other; if one had gained 99-100 of 1-5, the result would have been the same. So from this source alone there is an uncertainty of another 1-5 between the first and last cars, making 3-5 uncertainty.

Then we have the personal element. Mr. Woollen has suggested that it takes a very good man to press accurately to 1-5. I hope to test Mr. Woollen and Mr. Straight some day, and I shall not be surprised if they are generally nearer 1-50 than 1-5.

Still, even the best men are capable of making a mistake, and there is no means of finding it out. What we want is that the car shall, by passing the tape, make its own mark, and that if a mark is made at all it shall be incapable of an error which can be of any importance; that we now have. I have spoken of perfect watches and perfect men. When we get away from them, instead of being uncertain to the extent of 3-5, we must put on another 1-5 each at least for watch and man. And, to come down to the lowest class of timing, how many fifths we must add for the imagination of a constable on promotion is beyond the range of calculation.

Lastly, there is another serious drawback; errors cannot be corrected. When the watch is read and the knob pressed all real record is wiped out; all that remains is the written statement on a piece of paper of a fallible man. In the case of our own and many other timekeepers, they would probably be safe in betting each race 100 to 1, perhaps much more, that they made no error of pressing, reading, or writing. Still, even they are human, and there is no means of checking afterwards.

Now, Mr. Phillips, in 1887, got out this apparatus, which gets rid of some of the errors. The starting pistol closes a circuit, causes a magnet to press the knob of a stop-watch, and, similarly the breaking of the tape or other means at the finish presses it again. This use of one watch is a great advantage, as the extreme accuracy is only required when two are used. Say a watch gains 1 minute per day, which would be very bad for a common pocket one. There are 1,440 minutes in a day, so the error is only 1-1,440; so that in a 30 sec. race the error is only 30-1,440, or 1-50 sec. In addition to this, the human element is eliminated in pressing the button. It still has the human element of error as far as reading and writing go, and the watch still only reads to 1-5, so that there is still an uncertainty of 2-5 as at first, but no more. The record, however, is still wiped out, and cannot be checked.

* From a Paper read at a meeting of the Automobile Club, on the 10th inst.

An Automobile Procession at the St. Louis Exhibition.

CLUBS AND ASSOCIATIONS.

NORTHAMPTONSHIRE.

THE first of a series of lectures under the auspices of the Northamptonshire Automobile Club was given at headquarters, the Great Northern Hotel, Peterborough, on Friday evening, the 11th inst., when Mr. J. Montgomery, of the Peterborough Motor Company, gave a practical demonstration on a petrol engine. In the discussion, the respective merits of the automatic inlet valve and the mechanically operated valve were dealt with. The lecturer pinned his faith to the latter. For one thing, he said, the mechanical valve would keep the engine cooler than the automatic valve, and admittedly gave less trouble. The reason the mechanical valve was kept back was that there was 50 per cent. more trouble in making it, while it had to be sold at the same price as its automatic rival. Dealing with the question of vibrating and non-vibrating coils, the lecturer gave an opinion in favour of the former, although he admitted that far greater speed could be got out of the non-vibrating coil, and the consumption was less, but the latter gave a great deal more trouble. The lecturer advised them not to file their platinum points; if they gently hammered them it would make them all the harder. Nor should they let their accumulators run below 3·8, or better still, not below 4 volts. One motorist in Peterborough never had any trouble with his accumulators, because he had them recharged every week, whether they wanted it or not. If they put their motors away for the winter, or even for a short time in a damp atmosphere, they should take out the coil and keep it dry in the house, but the best thing to do was to ride the machine all through the winter. A vote of thanks to the lecturer for his lucid and entertaining remarks brought the very instructive evening to a close.

YORKSHIRE.

A WELL-ATTENDED general meeting of this club was held at headquarters, and ably presided over by Mr. Wilson. The principal business was to consider a proposal of the committee that an entrance fee be charged to all new members joining the club on and after January 1st, 1905. The alteration was put forward by Mr. Hey (Hon. Treasurer), who briefly outlined what was done by other clubs, and said that many new members

Digitized by Google

who had lately joined expected having an entrance fee to pay. Mr. Winn seconded the proposal. Mr. Exley moved an amendment that one guinea entrance fee be charged, but subsequently withdrew it, as it would prevent the matter being settled at the meeting. Ultimately the proposal was put to the vote and carried unanimously.

A discussion was then commenced by Mr. Pepper "On how to increase the attractiveness of the club," socially or otherwise. After mentioning the fact that club runs to different places did not seem to be a success, Mr. Pepper suggested that a few picnics be arranged to different places of interest, historical parks, moors, etc., and that members each take all their own refreshment outfits. Mr. Wilson supported this, and thought he could get permission for the club to visit two or three places of interest in the country.

Mr. Steel suggested that more use might be made of the club-room, and that a special club night be arranged on one evening each week, probably Thursday; a committee of six or twelve members be formed, two of whom would promise to attend on a certain evening, so that any member might be certain of meeting someone he knew on such night. Then again a suggestion board might be hung up, on which papers asking advice might be posted, or on which a member might notify that he would be pleased to hear of others to join in a special run or tour. Mr. Armitage suggested an arranged run each week during the summer.

All these suggestions were unanimously supported, and the committee will endeavour to have a busy programme arranged for the winter and following summer.

The fifth annual dinner, to be held on the 2nd prox., promises to be a great success. Mr. A. W. M. Bosville, of Bridlington, will occupy the chair.

THE SOUTHERN MOTOR CLUB.

THE committee of this club have arranged that the subscription of any gentleman wishing to join between now and March 31st, 1905, will entitle him to all the privileges of membership till the end of 1905. The club has decided to meet at the George Hotel, at Morden, Surrey, on fine Sunday mornings throughout the winter season. The annual dinner and distribution of prizes will take place at the Trocadero, W., on the 1st prox.

CLAIMS AGAINST MOTORISTS DISMISSED.

BEFORE Mr. Justice Darling and a common jury, the case of "Field and another v. Batstone has been heard." The action was brought by two brothers named Field against Mr. S. C. Batstone, of South Norwood, to recover damages for personal injuries, etc., sustained through the alleged negligence of the defendant. On the evening of Sunday, May 24, last year, the plaintiffs were proceeding in a pony trap from Ewell to London, and they alleged that when they reached Currey's-corner, Station-road, Ewell, a motor-car driven by the defendant, without any warning, dashed out of Monger-lane and struck the trap, which was overturned and smashed. The plaintiffs said they also received injuries which prevented them from following their employment for several weeks. The defendant denied negligence, and pleaded that the accident was due to the negligence of the plaintiffs. Judgment was given for the defendant, with costs.

IN the Belfast Recorder's Court, Henry Hutchinson brought an action against James M'Cammond to recover £19 19s., damages for personal injuries sustained by the plaintiff through the alleged negligence of the defendant or his servants in managing a motor-car on the Holywood road. The plaintiff stated that on the 20th September he was riding a bicycle along the Holywood road in the direction of Belfast. It was about 5.30 o'clock in the evening. A motor-car passed him going towards Holywood. Witness had a friend with him who was also riding a bicycle. He slowed up and went behind his friend, but subsequently came abreast of him. When in this position he heard a motor horn blowing, and on looking round the motor-car hit the right wheel of his bicycle, knocking him off and smashing his bicycle. H. W. M'Cammond, defendant's son, said the motor-car belonged to his father, but witness was driving on the occasion. He had been at Bangor that day with a friend, and was returning home, driving at a rate of eight miles an hour. He had the motor-car under complete control, and was in the centre of the road. He saw four cyclists—three on their proper side and one on the wrong side. Witness blew the horn half a dozen times before he came up. As he came up the man on the wrong side, who was the plaintiff, swerved round and turned right across witness's car. He turned a second time, and witness then struck him with his motor. Witness made every effort to avoid the accident. Dr. Watt, who came up, said the defendant was on the wrong side of the road. His Honour said the person on the bicycle was at first on his proper side, but he attempted to pass in front of the motor-car. If he had remained on his proper side the car would have passed, and no accident would have occurred. The action could not be sustained, and it would be dismissed.

THE Scottish Motor Garage Company, Limited, of Glasgow, have recently held what was, we believe, the first motor-car auction that has yet taken place in that city. These sales are intended to be held every month, and, from the attendance and number of lots which were sold on the first occasion, promise to become an important feature of Scottish automobile business.

CASES AGAINST MOTORISTS.

Place.	Summoned for	Fine.
Dunblane	Driving on prohibited road	£5.
Wilmslow	(1) negligent driving; (2) refusing to give name after an accident	(1) £10; (2) £10.
Bow Street, London	Beyond regulation limit in Green Park	42s.
Kingston	(1) driving dangerously; (2) refusing to stop	£10; £10.
Huddersfield	Exceeding legal limit	36s.
Birmingham	No rear light	20s.
Coventry	Excessive speed	Dismissed.
Marlborough St., W.	20 miles an hour in Hyde Park	20s.
Ayr	Driving round a corner without sounding horn	£5.
Ingleton	Unilluminated rear number	£2.
Harlow	Driving dangerously	40s., etc.
Cheshire	(1) Driving negligently; (2) refusing to give name after an accident	(1) £10; (2) £10.
Exmouth	Driving without licence	£2.
Brynmawr	No light	2s. 6d., etc.
Thames	Unilluminated rear plate	10s., etc.
Pollokshaws	No rear tail light	£3 3s.

ACTION OVER RELIABILITY TRIALS.

THE British Automobile Commercial Syndicate, Limited, sought to recover damages from the Automobile Club for alleged breach of contract in respect of a motor-car competition, which contract was denied by defendants, and the case has just been heard before the Lord Chief Justice in the King's Bench Division.

In the summer of last year the plaintiff company received an entry form and a copy of the rules and regulations relating to a 1,000 miles' reliability competition for motor-cars, arranged by defendants. It was to extend from September 18th to 26th, and each car was to start from and complete each day's run at the Crystal Palace. Plaintiffs paid the fee of £20 odd, and entered a 12 h.p. Clement car, to be driven by their managing director, Mr. D. M. Weigel. The latter drove the car to the Palace, and on September 17 was allotted a position for the following day's trial. On the 18th he drove the car to Margate and back, but was prevented by the officials, acting on behalf of the defendant company, from completing the trial the following day, on the ground that he was not on the club register.

Mr. H. Terrell, K.C., and Mr. Lynch (instructed by Mr. John Hands) appeared for plaintiffs; and Mr. Lawson Walton, K.C., Mr. Montague Lush, K.C., and Mr. A. Paget (instructed by Messrs. Firth and Co.) for defendants.

The case having been opened by counsel, Mr. Weigel gave evidence as to the facts of the case. Mr. Lush submitted that there was no case to go to the jury. So long as the club committee had acted bona fide they were entitled to act as they had done, and the plaintiffs could not recover.

The Lord Chief Justice pointed out that the revised rules of the competition contained no reference to the club rules at all. He ruled as a matter of law therefore that there was an unlawful breaking of the contract, because the competitions took place under special rules which did not incorporate the club rules.

The case resolved itself into a question of damages, and after some discussion these were fixed by the jury at £150.

Judgment was accordingly entered for the plaintiffs, with £150 damages and costs.

TO CORRESPONDENTS.

All communications intended for insertion in this Journal or relating to Editorial matters should be addressed to THE EDITORIAL DEPARTMENT, MOTOR-CAR JOURNAL, *39 and 40, Shoe Lane, London, E.C., and must be written on one side of the paper only. Letters must in all cases be accompanied by the name and address of the writer, as no notice will be taken of anonymous communications.*

The Editor cannot undertake to return MSS. or drawings, although every effort will be made to do so in the case of rejected communications. Where such are regarded as of value, correspondents are requested to retain copies.

To insure insertion communications and contributions must be in the Editor's hands by Tuesday forenoon of the week in which the same are intended to appear. Disappointment may be caused by non-compliance with this rule, and to avoid this earlier receipt, if possible, is necessary.

THE

Motor-Car Journal.

VOL. VI.] LONDON, SATURDAY, NOVEMBER 26, 1904. [No. 299.

Published Weekly by CORDINGLEY & CO., 39 & 40, Shoe Lane, London, E.C.

COMMENTS.

ONE of the most interesting features of the automobile year has hitherto been the Glasgow to London Reliability Trial of the Western Section of the Scottish Automobile Club. In the early stages of the industry this test was regarded as something to try the merits of cars and test the endurance of drivers. But in these days of lengthening long-distance trials it has been thought desirable to invite the views of the trade as to what the Scottish Club may reasonably be expected to do in the organisation of a trial north of the Tweed next year. Hence the appearance in our correspondence columns of a suggestive letter from Mr. R. J. Smith, whose enthusiasm and powers of organisation are likely to prove equal to anything that may be suggested. In view of the antagonism which is developing in some parts of Scotland towards the motor-car, it seems eminently necessary that something should be done in the direction of converting the local authorities as well as testing the vehicles. That idea should be borne in mind by motorists writing direct to the Scottish Club or making their views known through the columns of the *Journal* in order that full discussion may be elicited.

◆ ◆ ◆

Progress at Leicester.

IN inaugurating their winter session by a lecture on "Motor-cars," by Mr. E. Shrapnell Smith, the Leicestershire Automobile Club did well, and he, on his part, gave them an address full of information with regard to the history and development of automobilism. Mr. E. G. Mawbey, M.I.C.E., the president, was in the chair, and said that the automobile club had been a great success in Leicester. They had a large number of members, owning 70 motor-cars. There were 76 motor-cars and 106 motor-cycles in the town, and in the county of Leicestershire 107 cars and 187 cyclists, so that they would see the number of motorists was increasing. He urged all motorists to join the club, for "union was strength," and it was principally owing to the affiliated clubs that automobilists had the advantages they now enjoyed.

◆ ◆ ◆

Tests in South Africa.

So much has lately reached us concerning the advance of automobilism in South Africa, that the proposition for a series of trials in that country does not come as a surprise. Already some excellent long distance runs have been made in South Africa with various makes of motor-vehicles, and the inquiries that have been made as to the possible organisation of automobile services, both for passengers and goods, prove that the time is coming when reliability trials can be organised without insuperable difficulties.

◆ ◆ ◆

Lessons for Ladies.

IN arranging a series of technical lessons on the automobile for the benefit of its members, the Ladies' Automobile Club has done well, and Mr. Currie may be congratulated on the syllabus he has prepared for their edification. Many ladies are expert drivers and many more would rapidly become so if they felt the confidence which comes from knowledge of mechanical matters. These lessons should give them an adequate idea of technical terms, and the only suggestion we would make is the inclusion of an extra lesson dealing with the main features of steam and electrical vehicles. By this means a completeness would be given to the course and interest increased, in view of the popularity of these quietly-moving vehicles in society circles.

◆ ◆ ◆

A Club for the Argentine.

THE international aspect of automobilism receives further testimony in the formation of the Argentine Automobile Club. This has recently been inaugurated at Buenos Ayres, the capital of the Argentine Republic, and already has a membership of well over a hundred of the leading residents of the city. The hon. treasurer of the organisation is now on a short visit to England and has made application for the affiliation of his club with the A.C.G.B.I., a matter which is the subject of consideration in Piccadilly. The address of the club is "Automovil Club Argentino, Calle Maipu 1,241, Buenos Aires," and a reading room is being supplied with automobile literature from all parts of the world. Catalogues of English makers of motor-cars will be particularly welcome. An automobile show is also in contemplation by the club.

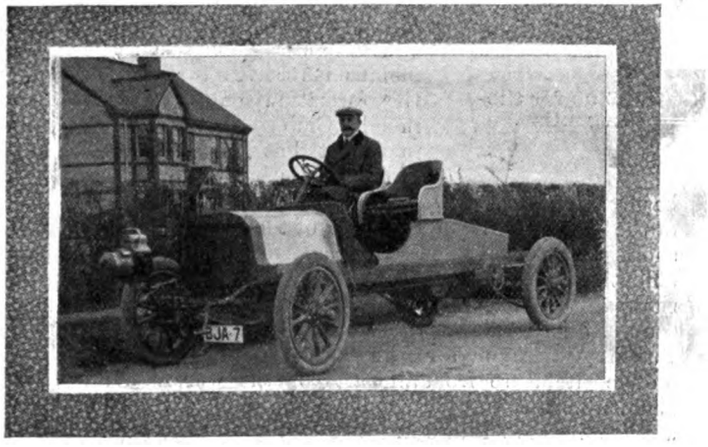
◆ ◆ ◆

Local Bye-Laws.

LOCAL bye-laws are often strangely worded and curiously devised to hinder progress. In Staffordshire there is one concerning motor-cars, which must not be stopped within 10 feet of the abutment of a county bridge—a piece of information which strangers are likely to ignore in their innocence of the existence of such a provision. A victim of such regulation has just been fined twenty shillings and costs for stopping his vehicle on the top of a bridge at Rushall. It might be well if notices were exhibited where such provisions exist, unless there is too great a danger of making our hoardings veritable motorists' guides.

◆ ◆ ◆

Motor Traffic on Roads.



SIR WALTER GILBEY has international reputation in connection with matters relating to horses, and his reflections on motor traffic and the public roads, as given out in this month's "Nineteenth Century," naturally deserve kindly consideration. He recognises that the initial difficulty to be got over in dealing with the problem is that of reconciling the conflicting interests of swiftly driven passenger motor-cars with those of other users of the highway. In coming to a conclusion Sir Walter recognises that the new traffic will necessitate both the widening and the improvement in methods of construction of the roadways. Firstly, swiftly driven cars on winding roads between high hedges are a source of danger to strolling live stock, wandering pedestrians and lumbering wagons. Heavy motor-wagons, on the other hand, built up to the maximum allowed by the regulations of the Local Government Board, would in many places practically close the lanes to other traffic. These two factors combine to make the work of reorganising British roadways a very expensive business, and Sir Walter Gilbey suggests, without answering, the question, "Who pays?"

Digitized by Google

Who Pays?

MOTORISTS can approach the question without any qualms. They have already contributed something to the county revenues in fees for registration and licensing; they have provided many districts with various fines unjustly inflicted, and they have thus contributed their quota to the expense of local government. But indirectly the automobile movement has revived the prosperity of many rural districts, given a new lease of life to numerous hotels, and generally re-awakened an interest in country life. What are the ratepayers to give in return? Surely Sir Walter will be quick to recognise that these, too, have a responsibility in the matter, and that the authorities must not expect motorists to pay to exist. This is a new philosophy of taxation, and one that is not likely to find much acceptance in an age in which philanthropy is not practised merely for the fun of the thing. Apart from this, however, the article is one that motorists should study, the historical information contained therein being particularly interesting.

◆ ◆ ◆

Mr. Max Pemberton on a 16-20-h.p. Brooke Car.

◆ ◆ ◆

Motor-Car Insurance.

MR. FREDERICK THORESBY, the general manager of the Car and General Insurance Corporation, Limited, has written a useful pamphlet on the insurance of motor-cars, in which he points out that the cost of insuring vehicles depends almost entirely upon the amount which an insurance company has to pay to or on behalf of its assured. There are four great directions in which an improvement in this respect can be effected, viz., removing the prejudice felt against motorists by abating the dust nuisance, reducing the risk of side-slip to a minimum, giving prompt notice of any likely claim that may arise, and regarding the policy as a deed of partnership between the insurance company and the assured. Mr. Thoresby's explanations of the various points that may arise in connection with insurance matters are extremely lucid and pointed.

◆ ◆ ◆

Horses as a Source of Danger.

SOME time ago we noticed the remarks of a coroner in Kent, who expressed his view that the automobile was not nearly the murderous machine that some would be inclined to regard it. Now comes similar testimony from the Halifax coroner, Mr. E. H. Hill, who, at an inquest in that borough arising out of a trap fatality, stated that there was a good deal of correspondence in the newspapers about motor-cars. Whilst, however, he had not yet had a case of death from a motor-car, this was the sixth or seventh accident from a horse-driven vehicle that he had investigated. This is a fact which cannot too frequently be urged. The horse-drawn vehicle is by no means free from danger, for here we have an animal of uncertain temper, likely to shy at any unfamiliar object which may come within its range of vision. On the other hand, the automobile is propelled by something of a mechanical nature conformable to certain laws and only requiring a steady, careful driver to secure absolute reliability of control.

◆ ◆ ◆

Where Roads are Narrow.

MOTORISTS can do something to secure better roads for next season's touring if they will continue to make, throughout the winter, urgent representations to the various local authorities. A resident of Sevenoaks has just drawn our attention to the narrowness of the main road from the bottom of Farnborough Hill through the village of Green-Street-Green onwards to Sevenoaks, and to the great danger to life arising therefrom. An enormous motor traffic has arisen along this road, and in fine weather as many as 400 outward-bound motors and five times as many bicycles have been counted on a single day. The roadway is only some twenty feet in width, whereas it should be at least forty feet to secure any measure of safety. It is impossible for motor-cars running at high speed in opposite directions to pass without the most imminent risk to the lives and limbs of their occupants on so narrow a roadway. Steps should certainly be taken to widen the road, at any rate in the most dangerous portions of it, for example, from Polhill to Green-Street-Green. Residents in other parts of the country where roads are narrow should be prompt to similarly indicate points of danger to motorists.

◆ ◆ ◆

Scottish Opposition.

IN connection with the renewed activity in Scotland against the motor-car, two or three incidents have lately been brought to our notice which seem to indicate a distinctly antagonistic attitude on the part of Scottish authorities. Broughty Ferry is taking a lead with the object of securing for burgh authorities the power to regulate the speed of motor-cars while driving through burgh streets. On learning that they were without power in the matter, and that the power rested entirely with the Scottish Secretary, the Town Council resolved to bring the question under the notice of the Member of Parliament for the county, with the view of impressing upon him the necessity of making some arrangement by which they could legally enforce an adequate rate of speed. Captain Sinclair, M.P., has consequently been interviewed, the Town Council being represented by Provost Gray and Councillors Lindsay, Scott, and Mackay.

◆ ◆ ◆

Possibility of Further Legislation.

CAPTAIN SINCLAIR indicated that personally his opinion was that burgh authorities should have full control in such a matter, and it was desirable that a reduced rate of speed should be enforced in burghs. After conversation it was agreed that the best method of having the subject raised would be by calling attention to the question at the Convention of Royal Burghs in April. A definite proposal might then be formulated, and Captain Sinclair pointed out, by way of suggestion, that a return showing the number and nature of accidents that had occurred would be of considerable importance, and perhaps of value in leading to the realisation of their wishes. Reference was also made to the confusion that would be caused in the event of different rates of speed being fixed in different burghs, and it was thought desirable that a standard should be agreed upon. Captain Sinclair gave no pledge to support any measure that might be brought forward without being fully aware of its provisions, but promised if a Bill on the reasonable lines indicated by the deputation were prepared and submitted that it would have his cordial support. Does this mean that a Scottish movement to restrict even the small advantages of the Motor Car Act is about to be initiated? In such an event the Scottish Club will have to be reckoned with, a fact of no small encouragement to motorists.

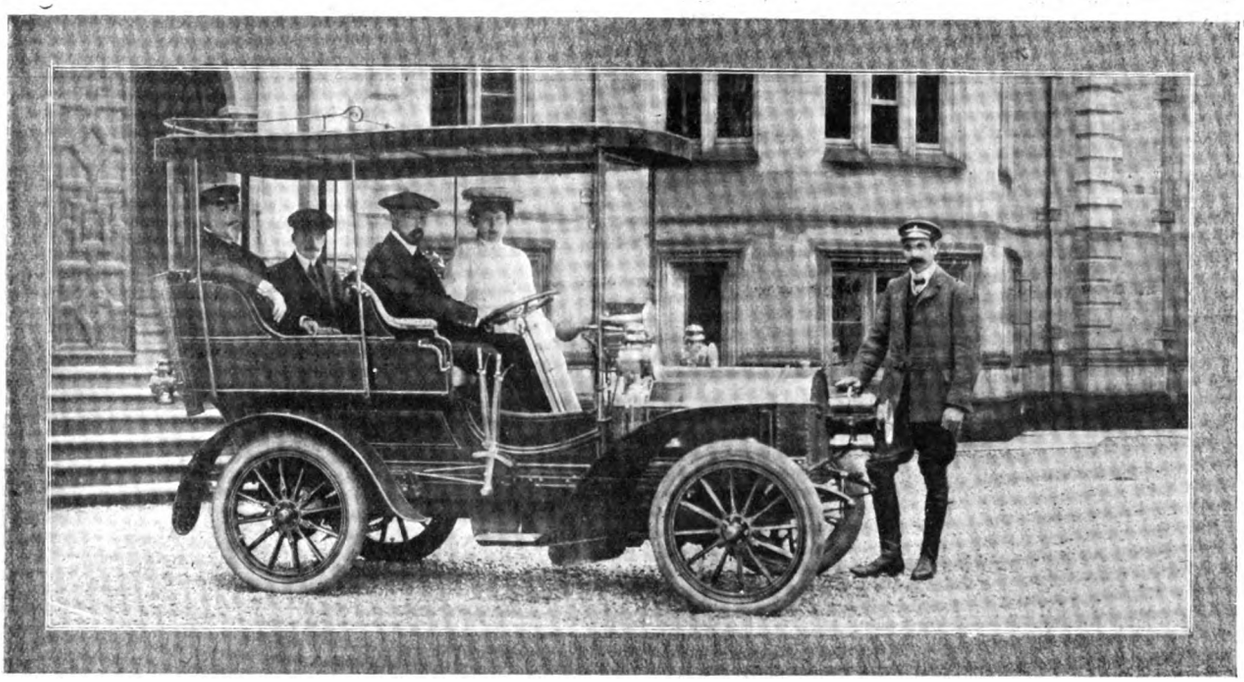
In India.

THE article by Mr. F. J. E. Spring in another page should be seriously considered by automobile engineers. Mr. Spring is the chairman of the Madras Harbour Trust, and asks whether English makers will not do their utmost to secure a carburettor working with paraffin in a thoroughly satisfactory way. Much attention has already been bestowed on this problem; more will have to be given if the great eastern markets are to be held by our manufacturers.



◆ ◆ ◆

In Twenty Years.

IN proposing the toast of the Motor Industry at the annual dinner of the Society of Motor Traders at the Hotel Cecil, London, on Tuesday, the Hon. Scott Montagu assumed the mantle of a prophet, and gave the horse another twenty burdensome years on the roads of the country. When two decades have passed he expects to see all the traffic that is now drawn by horses in the hands of automobilists, and the horse finding pleasant exercise in the hunting field, and for the delight of man—

Kent apparently satisfied.

IN two southern counties the question of new regulations with regard to motor-cars has lately been discussed by their respective County Councils. At the Kent County Council, the Hon. and Rev. E. V. Bligh moved, "That it be an instruction to the Bridges and Roads Committee to consider and report to the Council whether any regulations can advantageously be made for the better protection of infants and children upon highways near schools and wayside houses, and generally for the greater safety of human life in streets or on roads of a populous and semi-urban character" The motion was discussed

The Grand Duke Michael of Russia and the Countess Torby on their 14-h.p. Dennis Car.

[Photo by] [Harry F. Phillips, Leek.

rather than in toiling wearily with heavy loads. Such an advance means that a whole crop of interests will have to be encountered, all the trades allied to matters affecting the horse recognising that they will have to find fresh avenues of employment. In view, therefore, of the growing opposition that is coming, motorists must be careful to do nothing to prejudice their case in the eyes of the public. Such was the strain running through most of the speeches at the celebration of the existence of a Society which, with the Automobile Mutual Protection Association, and other organisations, is naturally interested in the development of the motor-car industry.

◆ ◆ ◆

Another Trophy.

NEXT summer will probably see the first touring competition for the Charles J. Glidden Touring Trophy (a 2,000 dol. silver one), which has been offered by Mr. C. J. Glidden for a tour of not less than 1,000 miles, the deed of gift of which was accepted at the meeting of the board of governors of the American Automobile Association. By the Glidden deed, the tour must be held in the United States for three years, beginning in 1905. The contest must be not less than 1,000 miles and not less than 500 miles a week. All rules governing the contest shall be fixed by a committee of seven, consisting of the president of the American Automobile Association, who shall be the chairman, the donor, and the Presidents of the Automobile Club of America, of Great Britain and Ireland, of France, of Germany, and the President of an Automobile Club in Canada, to be recognised by the American Automobile Association, or representatives selected by them.

◆ ◆ ◆

Signposts in Hampshire.

THE Hampshire County Council has decided to erect warning boards where dangerous places are likely to cause accidents to motorists, and in submitting such a suggestion the chairman of the committee which made itself responsible for the idea said they had received £350 for motor car licences, and he had no doubt the amount would be doubled ere long. So that it would appear that these county councillors rightly recognise the valuable source of revenue that motorists have become to the local authorities. There must be some sort of reciprocity, even if it only amounts to warning motorists where they stand a chance of breaking their necks. During the last nine

and defeated—a very satisfactory conclusion. This is a matter in which teachers and others who come into constant contact with children can do much good by emphasizing the necessity for the roads being left to vehicular traffic as far as possible and not to be used as public playgrounds. If children would realise that fact the risks of danger would be considerably lessened not only so far as motor cars are concerned but general traffic as well.

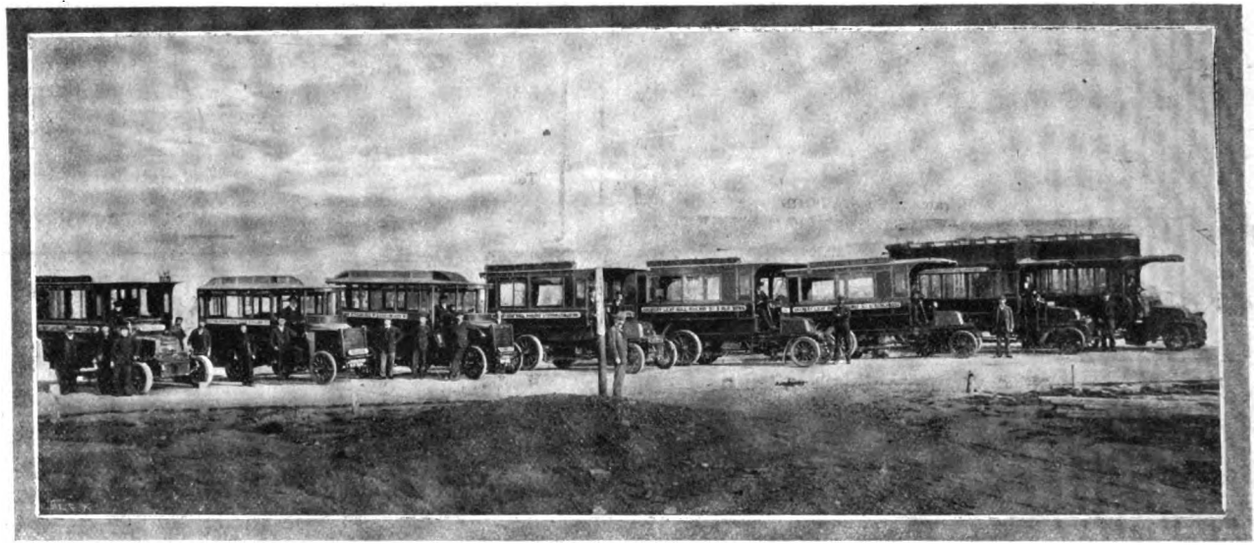
◆ ◆ ◆

Digitized by Google

months there have also been eighty-three prosecutions in Hampshire, convictions being obtained by the police in sixty-six cases.

◆ ◆ ◆

Horseman v Motorist.



OFTEN have motorists been threatened with personal violence by infuriated drivers of ordinary vehicles, and cases in Scotland and at Guildford have been the subject of magisterial investigation. Scores of others would have been equally the object of inquiry, but difficulty of securing the offender and obtaining reliable independent testimony has generally stood in the way of prosecutions. At Epsom, however, Mr. Montague Jones, of Croydon, has been able to administer a salutary warning to a gentleman of Hook who slashed a whip about the occupants of a car and hurled various epithets at the motoring party. In the police-court Mr. G. Bird, the defendant, was fined the maximum penalty of £5, and some useful advice given with regard to the advisability of keeping his temper in future. But apparently £5 is the maximum penalty in such a case—a very small amount compared with the fines which may be inflicted on motorists; even those who do not constitute themselves a nuisance and annoyance to other people.

Dewar, M.P. This new trophy will be put up for the international record mile race, and teams representing the different countries will compete for it. Heats will be run by countries, the winners of the heats coming together in the final. Besides presenting this trophy, Sir Thomas has promised to be present at the tournament and to act as associate referee with Mr. A. R. Pardington, of the American Automobile Association racing board, and Mr. S. A. Miles, of the National Association of Automobile Manfacturers. The programme will include twenty-five events, and it has been decided that all entries will be by invitation only.

◆ ◆ ◆

In Central Africa.

IN his report on the trade and general condition of the British Central Africa Protectorate, H.M. Commissioner and Consul-General at Zomba (Sir A. Sharpe, K.C.M.G., C.B.) writes:—"On our main roads there is, I think, little doubt that motor-cars and motor-cycles will be used to a considerable extent before long. During the eight dry months of the year there is nothing to prevent light motor vehicles from travelling the whole distance between Chiromo in the south and Lake Nyassa in the north. An enterprising cyclist last year travelled by motor-bicycle from Matabeleland to Fort Jameson in North-Eastern Rhodesia, most of his journey being over native paths. Bicycles are largely used in British Central Africa; and when baggage can be sent ahead, provide one of the best means of locomotion over a great part of the Protectorate." Hardly a week passes when we do not hear of the interest with which the automobile industry is now regarded in Africa—north, south, east, west, and central.

The Fleet of Municipal Public Service Vehicles at Eastbourne.

AUTOMOBILISM IN INDIA.

By F. J. E. Spring, C.I.E.

TO the English maker of cars India is a very far-away place. Doubtless; but in a half-hearted kind of way he tries to get a footing in the Indian market. But the impression his spasmodic effort leaves on the mind of the average Indian motorist is that the English car-maker is too busy supplying the needs of the home country, and too insularly ignorant in regard to Indian conditions, to make a business-like bid for the Indian trade. The consequence is that French and American cars are cutting him out; and, just as the French have already pretty well captured the car trade in the Federated Malay States, where the De Dion-Bouton reigns supreme, so they and the Oldsmobile and Locomobile people will get a real footing in India if English makers do not soon realise the position. It must be recognised that the British merchant at the chief cities does not very much mind what agency he takes up, English or foreign, so long as he gets his commission, and that the world of Indian purchasers is very much in the hands of the local agent.

What we users of cars in India have chiefly to complain of is that the makers of internal combustion engines will insist on forcing on us an engine with a carburettor suited only to the use of petrol. Now India is a biggish place, just about the size of all Europe including the British Isles, with Russia cut off. It is a country of rich men of the native land-owning class, and of fairly well-off English officials, who, as a class, are sportsmen, and would like to use motor-cars, as well as their stables full of horses, if only the makers would take the trouble to learn the local conditions, and supply what is required. What is wanted will be understood from the following:—

The temperature inside an iron-covered goods wagon during several months of the year may run as high, for some hours of each day, throughout great tracts of India as large as France and Germany, as 150° F. Similarly, in the towns, or in private houses, where petrol is likely to be stored, the temperature may run up, for like periods, to anything between 105° and 125°. Now, these are not very nice temperatures for petrol, and the consequence is that the Government, who practically own the 27,000 miles of Indian railways, and who, moreover, are responsible for the public safety in general, whether on the railways or elsewhere, find it necessary to place such onerous restrictions on the carriage of petrol that, except in a few large towns, the motor-car owner is practically unable to replenish his tank. Throughout India there are probably hundreds of officials, with administrative areas the size of an average English county, who would be only too glad to take to motoring for their everyday business but for this trouble about petrol.

At this moment a conference of all the railway managers of India is sitting in conclave, and one of the subjects under consideration is the possibility of permitting consignments of ten gallons of petrol to be despatched by passenger trains. At present the motorist can only carry two gallons at a time, and he must be himself a traveller in the same train. In other words, as a convenience to motorists travelling by train, they are allowed to be accompanied by a two-gallon tin of petrol. If they want any further supply it must be sent ahead of them by goods train, and in this country of magnificent distances that may mean that it must be arranged for weeks ahead. Now there is not the smallest use in the stay-at-home British maker of cars thinking to himself, "This is all wrong, it ought to be altered." Doubtless it ought, but it will not be altered to suit his convenience. Meanwhile he is losing his trade to Americans and others, who, instead of saying "The conditions of a country of 300 millions of people must be altered because my drummer has not put me up to the tip to meet these conditions," say, "How can I adapt myself to the conditions of the country"?

I have explained what these conditions are as regards petrol. There is no trouble, except the cost of it, two to three shillings a gallon, in certain great cities; but throughout the rest of this vast country there simply is not any petrol, and there is not going to be any, whatever the British car-maker may think. Then he will doubtless ask, "What is there to take its place?" There is paraffin oil to take its place—kerosene we call it—in unlimited quantities. There is probably not a petty hamlet of half-a-dozen huts along the roads of India, throughout the length and breadth of the land, where kerosene cannot be bought. Not high-flashing oil that is only burnt in rich people's houses, but low-flashing Russian, or Burma, or Borneo oil, say 120° flash point, most of it imported in bulk and run all over India in bulk oil cars, to be stored in tanks near the railway stations for sale to the villagers either in bulk or re-canned; much of it also imported in cases. Anyhow, there it is, in practically unlimited quantities, and of universal consumption, distributed evenly and cheaply all over the country.

Motoring on a South African Veldt. *Automobil Welt.*]

But the English car maker *will* insist on putting carburettors on his car, chiefly of the float type, which do not permit of kerosene being used. We owners of cars are curious to know *why* he does this. Is it his insularity? or is it cussedness? or is it the intensely British idea, "Take my goods or leave them"? For the last month an American Oldsmobile has been running about Madras, some twenty to thirty mile daily, on common kerosene (paraffin) oil. The carburettor, not a float one, serves equally well for petrol and for kerosene when once warmed up. Therefore, the owner starts his car for about 100 yards on petrol and then changes over to kerosene. While petrol here—in a seaport where it is comparatively cheap—costs 3s., kerosene costs only 6d. per gallon. Therefore if, as appears to be the case, both do the same mileage per gallon, the saving on 6,000 miles in a year, at thirty-six miles to a gallon, will be about £20 in a year, or enough to provide the owner of the Oldsmobile with a new set of tyres annually.

But the saving in cost is a trifle compared with the car's ability to take its owner practically everywhere, throughout the length and breadth of India.

CONTINENTAL NOTES.

A Marine Motoring Congress.

It is announced that a Congress on Marine Motoring is to be held during the course of the Salon in Paris next month. The congress, which will probably be under the patronage of the French Admiralty, is being organised by the Association Générale Automobile, and already the arrangements for it are well advanced. One of the principal objects of the conference will be to attempt to arrange the differences between the various societies of encouragement which have arisen as a result of the great development of marine motoring as a sport and pastime.

◆ ◆ ◆

Public Services in Austria.

A public service of motor-cars was recently established between Tetschen and Bodenbach. The results have proved so satisfactory that a proposal to organise a similar service between Leipa and Reichenberg is under consideration.

◆ ◆ ◆

Nailsion Roads.

At its meeting last week the committee of the Automobile Club de France decided to offer a reward of £20 to any person giving information that will lead to the discovery of the individuals who maliciously spread nails on the Dourdan road during the progress of the international motor-cycle race in September last.

◆ ◆ ◆

A Group of German Military Motor-Car Drivers.

◆ ◆ ◆

The Renard Motor Road Train.

Some trials with the Renard motor road train, which attracted so much attention at the 1903 Salon in Paris, were carried out at the military depot at Schoeneberg, near Berlin, last week, in the presence of several leading Prussian military officials.

◆ ◆ ◆

A Motor Racing Track for Berlin.

According to the *Berliner Tageblatt*, arrangements are in hand for the establishment of a large motor racing track at Ruhleben, between Charlottenburg and Spandau.

◆ ◆ ◆

A French Motor Union.

As a result of the persecution of motorists by the police which has recently taken place in many parts of France, the *Auto* announces that it is taking steps to form a "Ligue des Chauffeurs," somewhat on the lines of the Motor Union in Great Britain.

◆ ◆ ◆

The Delhi-Bombay Reliability Trial.

Considerable interest is being shown by French motor-car builders in the forthcoming reliability trial in India. The Richard-Brazier Co. have sent out a car for the competition, and the De Dion-Bouton have despatched one of their 12-h.p. vehicles. It is probable also that the Darracq, Clement-Bayard, and De Dietrich companies will be represented in the contest.

◆ ◆ ◆

A Flying-Machine Exhibition.

The Aero Club of France has applied to the authorities for the use of the huge Galerie des Machines in Paris, in February next, to enable it to hold an exhibition of flying machines. The building, which is one of the largest in the French capital, formed part of the great Exhibition of 1900.

◆ ◆ ◆

Automobile Regulations in Holland.

It is stated that the Dutch Parliament has agreed to a Bill which entirely removes the speed limit in Holland, and permits motorists to drive at any rate, with the reservation, however, that the responsibility of so doing lies entirely with the driver of the car.

◆ ◆ ◆

Another Long Tour.

Quite an epidemic of long tours appears to have broken out in Paris. Cormier is away on one on a 15-h.p. De Dion car; Baron is touring France on a Bailleul motor-bicycle; and, as recorded last week, Osmont is submitting one of the new F.N. four-cylinder motor-bicycles to an extended trial. It is now the turn of the Oldsmobile, one of which, with M. Maurice Fournier, brother of Henri of that ilk, at the wheel, set out on Saturday last on a 4,000 kilometre tour of Europe. The route is:—Bordeaux, Marseilles, Genoa, Rome, Venice, Budapest, Vienna, Dresden, Berlin, Hamburg, Amsterdam, and Brussels. It is expected that the trip will be completed in twenty days.

◆ ◆ ◆

The Automobile Industry in Belgium.

The Cockerill Company, of Seraing, the great Belgian iron and steel concern, has taken up the construction of steam motor-wagons, several of which have already been sent to the Congo. A department has also been added for the building of motor-boats. The one lately completed is 30ft. long, and is fitted with a 35-h.p. Germain petrol motor.

◆ ◆ ◆

Another Heavy Vehicle Competition.

The Automobile Club of Marseilles proposes to organise a heavy vehicle competition next year. The trial will be carried out on somewhat novel lines, each vehicle entered being put into practical service with a firm of carriers for at least a fortnight.

◆ ◆ ◆

The Liedekerke Cup.

The race for the Liedekerke Cup, organised by the Belgian Automobile Club, for tourist vehicles, classed according to their cylinder capacity, will be run off at the end of April or the beginning of May over a 104 kilometre course, starting from and returning to Dinant.

◆ ◆ ◆

New Cars for 1905.

Three of the largest French engineering concerns will make their *début* in the motor world at the forthcoming Salon in Paris—Niclausse, Delaunay-Belleville, and the Westinghouse Company, of Havre. The last-named concern has lately turned out its first petrol car—one of 28-h.p. For the coming season Messrs. Chenard and Walcker are introducing a 12-h.p. and an 18-h.p. car, each with four-cylinder engines. Messrs. Vinot and Deguingand will also confine their attention to four-cylinder cars, these being of 10-h.p., 14-h.p., and 20-h.p. respectively.

◆ ◆ ◆

The Gordon Bennett Race.

It is reported that no less than five firms which did not compete for a place in the French team for the 1904 Gordon Bennett race will take part in the eliminating contest for next year's team, among these being Renault, Berliet, and Charron, Girardot and Voigt. It is also rumoured that the Mercedes car which Baron de Caters will drive for Germany will be of no less than 140-h.p.

Digitized by Google

THE ROVER 8-h.p. LIGHT CAR.

THE details of the car designed by Mr. E. Lewis and put on the market by the Rover Cycle Co., Ltd., are of such an original and novel character that a description of the vehicle will, no doubt, be of interest.

It will be seen, on referring to Fig. 1, that the *chassis* is a departure from usual practice, and that in the ordinary sense of the word there is no frame, the engine crank case, the gear box and back axle being so coupled up in one continuous aluminium case as to serve the purpose of both frame and mechanism receptacle, forming one continuous girder, and at the same time allowing of flexibility of movement between the front and back axles, which accommodate themselves to the varying surfaces of the road.

This girder and the back axle are coupled up as one whole, while the front axle is provided with a transverse spring suspended at each end by links from the castings forming the steering brackets. In the centre of the spring is clipped a bracket forming a seating for a link bracket on the front of the crank case of the engine, both being held together with one bolt, thus forming a kind of swivel joint, while to keep the front axle in line with the back axle two flexible-jointed stays are connected to clips on the front axle and the girder part.

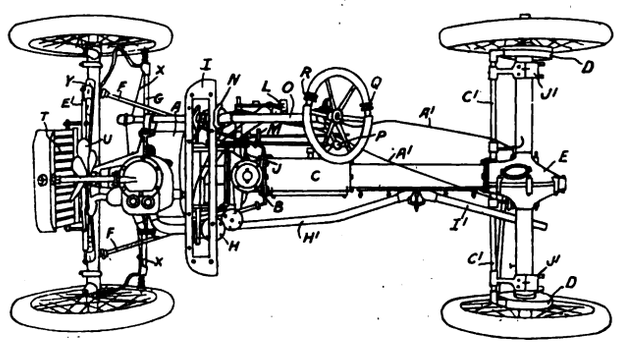

Fig. 1.—Plan of Chassis of Rover Car.

A Engine crankcase.
A 1 Steel Cables for Foot Brake.
B Clutch Case with Inspection Lid.
C Gear Case.
C 1 Rear Brakeshafts.
D Rear Brake Bands.
E Bevel Gear Case and Rear Axle Case in two half castings.
E 1 Swivel Bar for front part of body.
F Compression Rods for front axle.
G Cross Connecting Rod for steering levers.
H Carburettor.
H 1 Exhaust Pipe from engine to forward part of silencer.
I Aluminium Bracket to make up dash and support various parts.
I 1 Exhaust Pipe from rear part of silencer to the atmosphere.
J Foot Lever to operate cams on the engine half-time shaft.
J 1 Brackets to carry the rear body springs and brake bracket.
L Foot Lever for rear brakes.
M Clutch Pedal.
N Quadrant for change speed gear.
O Steering Column.
P Gear Changing Lever.
Q R Throttle and Ignition Control Discs.
T Radiator.
U Fan.
X Wire Steering Connections.
Y Cross Spring for front part of chassis.

The dashboard, which is separate from the body, is made up in two parts, the lower one consisting of a cast aluminium skeleton framework, having deep curved corners and lined outside forward with sheet aluminium, the part facing the seats forming recesses in which are placed the carburettor, the coil and the accumulators. The two-seated body is made up in a special way, the sides being each a cast aluminium skeleton frame secured at their bottoms to ash side members, and having panels of wood filled in at the sides, while the seats secure the frames at the top, thus forming the body, to which the rear dumb irons and springs are attached, and which in turn are clipped on to special brackets on the rear axle. As no part of the machinery is connected to the body except through the front spring, little or no engine vibration is felt. The motor is of the single-cylinder vertical type, having a bore and stroke of 4½ in. by 5-in. respectively. The cylinder is amply water-jacketed, as also are the valves, the top of the jacket above the combustion chamber being provided with a removable aluminium cover to allow the jacket to be examined and cleaned when required. The valves are both mechanically operated from the half-time shaft by cams of special taper formation, and a second pair of cams are also provided, the whole capable of being moved to and fro along the time shaft and operated by a foot lever. When this lever is in its normal position, the valves are performing their work, but by gradually depressing the lever the engine can be slowed down to a very low rate of speed, owing to the decreasing lift of the valves by the taper-faced cams, until at a certain point the cams are thrown out of operation, and the second set of cams is brought into play, converting the engine into an air compressor, the air being taken in through the exhaust valve, compressed, and then released as the piston reaches the top of its stroke, this air compression taking place at every revolution of the crank shaft, the inlet valve meanwhile remaining closed. The result is a very powerful check on the speed, but without any jar, enabling the driver to steady the car downhill or in traffic with the utmost ease. In addition to the cam control of the valves, there is also provided a throttle control to the carburettor, and a control of the ignition by means of Bowden wires operated by knurled fibre discs built in with the rim of the steering wheel, at opposite points, and by twisting or rotating these discs the wires are either drawn up or slackened as required. The crank shaft is of the solid block type cut from a solid steel forging, and has fastened to the outsides of its webs two internal flywheels, which are secured thereto by machined guides, by which the fixing bolts are relieved from all driving strains. The crank shaft—as also the half-time shaft—runs on special ball bearings. The water circulation is by a pump, the rotating body of which resembles a double-bladed propeller, and is driven direct off the half-time shaft of the engine. The radiator is placed in the front opening of the bonnet, and has a top and bottom tank, which are connected together by gilled copper tubes against which the air impinges. There is in addition a belt-driven fan placed behind the radiator to produce a draught of air through it. The usual form of electrical ignition is adopted, the accumulators and coil being contained in a box in front of the driver.

(To be continued.)

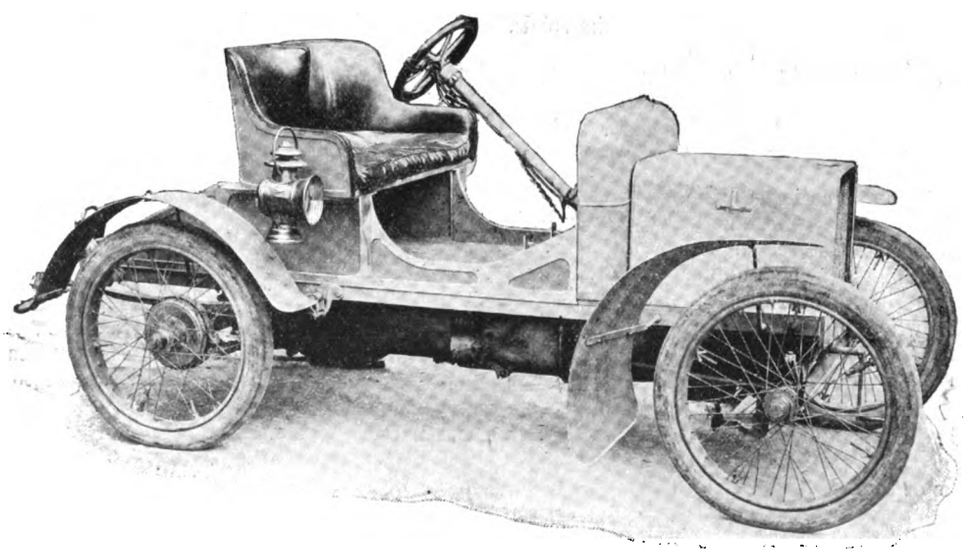

Fig. 2.—General view of Rover Light Car.

IN Poland-street, W., the Lacre Motor-Car Company, Limited, have vast premises, to which reference was made some months ago when first occupied. They are now thoroughly equipped and organised for a business which grows practically every week, and is becoming a very comprehensive one. In this large building of five floors repairs of a general character are carried out, and a large amount of body-building is going on. In addition to being the London agents for the Wolseley and Lanchester cars, the company does a general garage business, and has opened a motor clothing show-room, which should further extend its favour among motorists.

MOTOR CYCLING NEWS.

THE motor-cycle section of the Austrian Automobile Club proposes to hold a reliability competition for two-seated motor-cycles early next year. A trial of non-skidding devices for motor-bicycles is also to be held.

FIVE firms are reported to have responded to the invitation of the motor-cycle section of the Austrian Automobile Club to enter machines for the 1905 International motor-cycle cup race. As each firm will enter three machines, there will be altogether fifteen in the eliminating contest which will have to be held to select the Austrian team.

IN the recent motor-cycle race from Pretoria to Johannesburg a new time record was established by Mr. A. Murkett, who rode a 2¾-h.p. Vindec Special fitted with ordinary Palmer motor-cycle tyres. Mr. Murkett won the silver challenge cup and beat the previous record by 16 min.

TAKING advantage of the many provincial motorists at present in town for the Stanley Show, the Motor-Cycling Club organised an invitation run to Slough and district on Sunday last. Notwithstanding the somewhat greasy state of the roads, a fair number turned out both on cars and cycles, as will be seen from the accompanying illustration. Lunch was taken at the Royal Hotel, Slough, and short spins indulged in to Windsor, Eton, and other places of interest in the neighbourhood.

The meet of motorists at Slough organised by the Motor Cycling Club.

Photo by] [*E. W. Ashworth.*

IT has been reported at a meeting of the Surrey County Council at Kingston-on-Thames that since the 1st of January this year 826 motor-cars have been registered in the county, and that 2,483 drivers have been licensed. The number of motor-cycles registered was 804, the number of manufacturers registered was 22, and the changes of ownership registered 16. The receipts from these sources were £1,733 5s., which, added to the fines imposed on motorists in that county, should make a goodly total.

MESSRS. HUDSON AND KEARNS' Blotting Pad Diaries are familiar objects on office desks, and, being strongly made and filled with blotting paper of better quality than usually appears in such annual reminders of the flight of time, are likely to retain a permanent place on the office requisition list. The pads are made in several sizes with different features, including calendars, writing paper, date remembrancers, memo. tablets, etc.—all well adapted to the requirements of busy men.

THE CONSTRUCTION OF SILENCERS.

SILENCERS consisting of concentric cylindrical chambers are still used a great deal on motor-cars, the usual arrangement being to lead the hot gases into the central chamber at one end and allowing them to pass through fine perforations in the walls from one chamber to another, and finally to escape into the atmosphere. Usually the chambers increase in size from the inner to the outer one, the theory being that as the gases pass from one chamber to the next they have a larger space to occupy, consequently expand and lose pressure. It is well known, however, that this type of silencer is not particularly effective, unless the perforations are very fine and small in number, so as to introduce a great deal of resistance to the escape of the gases. A more logical arrangement of the concentric-chamber silencer is, remarks the "Horseless Age," to lead the hot gases from the engine into the outer chamber first, and let them escape from the central chamber. The outer chamber is naturally the larger one, and the gases should be allowed to expand to the greatest possible volume before encountering any obstruction. Of course, the passage of gas must be obstructed to a certain extent, if noise is to be effectually reduced, but the obstructions should be placed as near the point of discharge to the atmosphere as possible, and far removed from the inlet from the engine. Another even more important advantage of passing the gases through the silencer from the outer to the inner chamber is that the cooling effect is thereby much improved. The only method of effecting a noiseless discharge of the exhaust gases, besides throttling the exhaust passage, is to deprive the gases of their heat, and the latter method is by far the preferable one, as the pressure of the exhaust can in this way be reduced without causing any back pressure on the engine. When the gases are led directly into the outer chamber almost the entire exterior surface of the silencer is available for radiating purposes, and much heat is abstracted from the gases before they leave this chamber. In this connection it will readily be seen that lining or covering the silencer wall with asbestos or other heat-insulating material is inadvisable, unless the silencer is so located that a person is liable to burn his fingers on it while making adjustments on the motor. Another factor that deserves attention in designing silencers is the possibility of the small perforations becoming clogged with lamp-black or carbon dust. With a concentric chamber silencer in which the gases pass from the outer to the inner chamber, the perforations may be made so large that clogging is practically impossible.

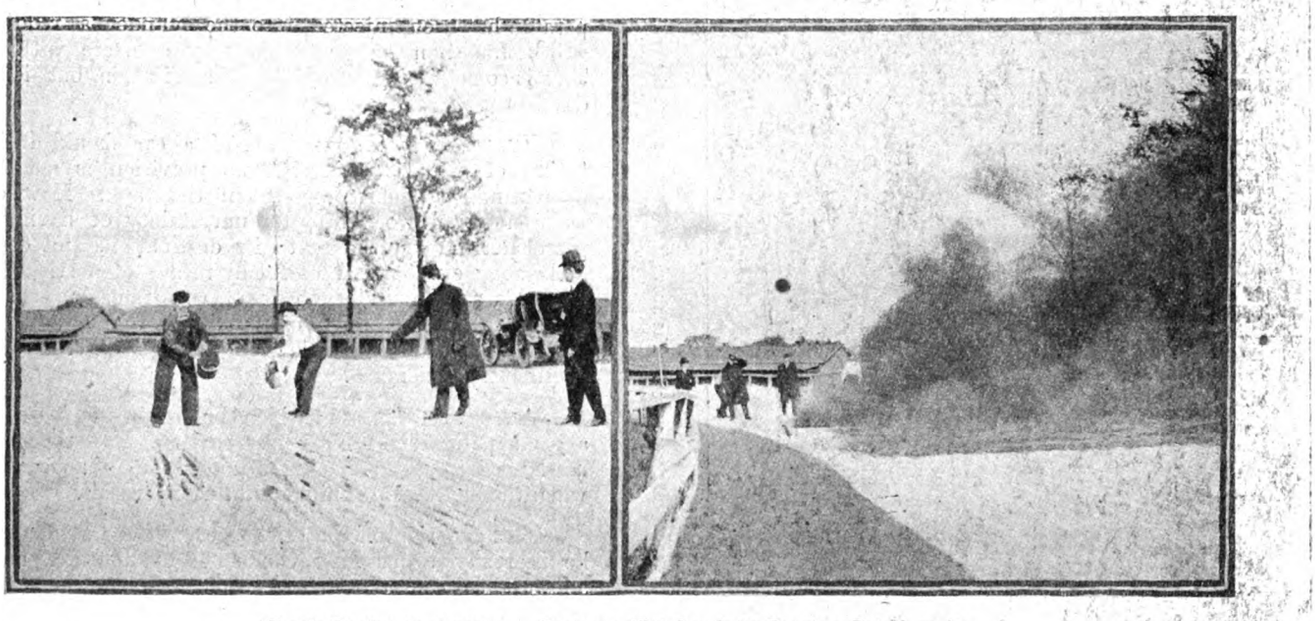
THE IMPORTANCE OF ALIGNMENT.



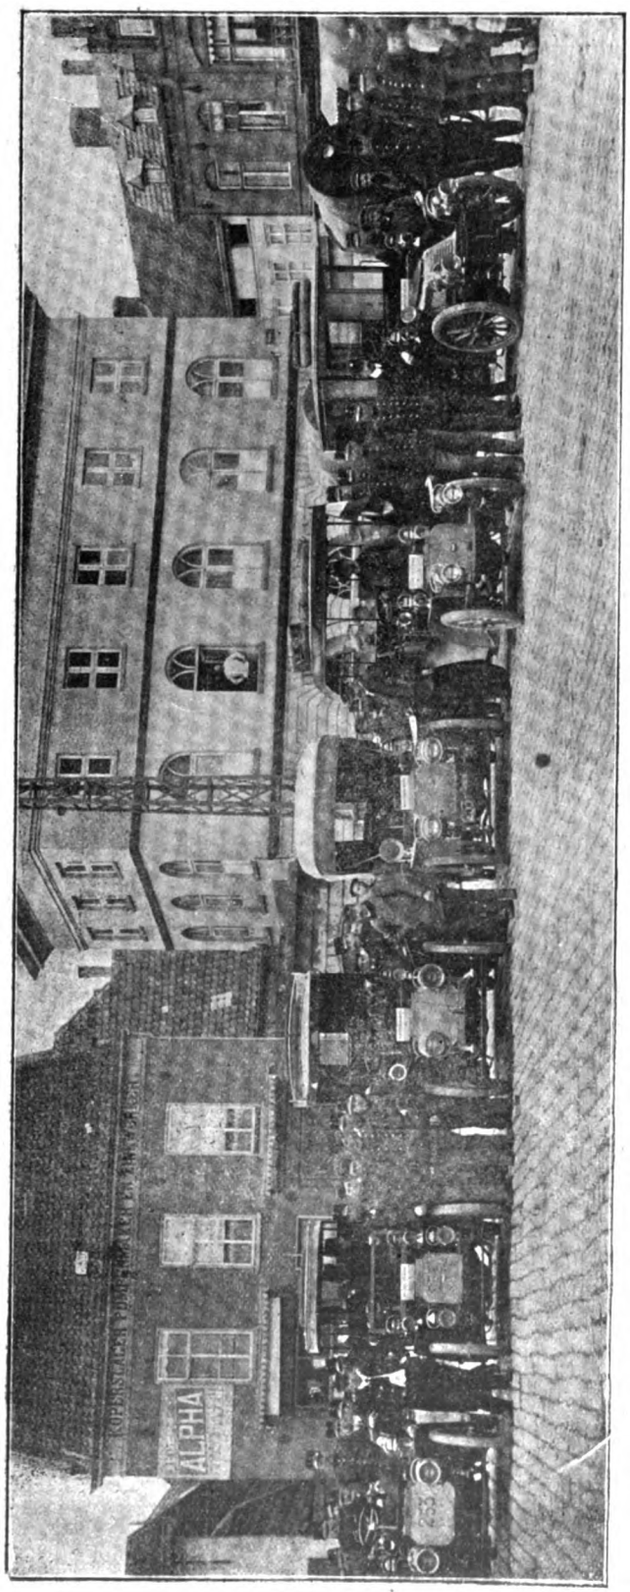
STRIPPED of all the technical language it is covered with, briefly the engine of a motor-car is the power maker, the gear is the distributor, and the hind wheels are the means of giving effect to the power generated by the motor. In the course of the transfer of this power some portion is lost through mechanical causes, which is best understood by the term frictional resistance. It should therefore be the aim of all mechanical design to reduce to the lowest possible amount this loss of power, and so to get a final output approximate to the initial one. The results shown are termed the mechanical efficiency of the machine. Judged from this standpoint, it is to be feared that the motor-car falls far short of the ideal. This, in a sense, explains what is difficult to the comprehension of the ordinary man—why a car to do even moderate work at a fair speed requires such a large horse power. To approximate or proportion the amount of loss between the several parts that convey the motor power would be too difficult, and of a variable quantity, differing with the types of transmission, as, say, between a simple chain-driven gear and a bevel gear drive, or a fixed axle and a live or rotating one.

By the term "alignment" is understood the setting out, or levelling, of the component parts of the car whereby all possible causes for undue friction are removed, and the power is distributed in as direct a way as is mechanically possible. In engineers' shops the practice is invariably to work from a centre line. In the case of engines, this runs fore and aft the cylinders; in machine work it is drawn on the casting, and then centre-punched to retain its presence, and any material to be removed is carefully divided by means of the centre line used as a gauge. The importance of this is so marked that the smoothness in running when the whole engine is assembled is to be measured by the carefulness with which this lining out has been done. When one considers that a deviation of but one-sixteenth of an inch per foot on a total length of, say, six feet will mean an error of upwards of a quarter of an inch, some idea, remarks a writer in the "Automobile Magazine," may be gathered of the important bearing this point has on mechanical construction.

Applying this idea to motor-car construction, we know that not only is there a thrust on the propelling parts in one direct line, but it is in a transverse direction also. That is to say, at the point on the gear where the direct action of the motor ceases the power is further transmitted by the transverse line, or, in other words, to the road axle, which may be said to run at right angles to the centre line of the drive. Therefore, an error of one-quarter of an inch in a length of six feet will make a very considerable difference in an alignment or disposition of the driving wheels or axles. Its effects will, no doubt, appear only a little at first sight on the pitch line of the teeth, say, of a bevel gear, but if looked at a few months after use the results will begin to be more marked. It will be somewhat the same where chain transmission is used, only not quite so evident, as the elasticity of chain will take up some of the ill effects, but all the same, the the sprocket teeth will show a corner-wise wear, and so continue until the chain has stretched sufficiently to give the required amount of play.

Makers no doubt think, and perhaps with some reason, that the cardan shaft, with its flexible, or give-and-take, knuckle joints, should correct any of these errors. Within limits it no doubt will, but it is to be feared, judging by appearances, that some of the cars in use are put together with far too much dependence on the possibilities of this flexible shaft. Otherwise how can one explain the building of a *chassis* where the engine and gear box appeared to be set square to the frame, but with the propeller shaft tilted to an angle of quite 45 degrees from the horizontal plane. The amount of power such an arrangement will absorb would no doubt be interesting to test. With such well-constructed gear boxes and motors as are now the rule, extra labour involved in accurately setting them into position on the *chassis* should not be grudged.

This labour might be still further lessened if the practice of building engine and transmission gear on a self-contained base was more largely followed. It would not impair the flexibility of the structure, but would rather prove a means of bracing together the frame, and tend to prevent the whole getting out of alignment when in use. With a sensible wheel base, semi-elliptic springs, not too rigidly held either in fixed scrolls or equally useless shackles, but having a free means of expansion under stress, and fitted with pneumatic tyres of suitable size for the weight to be carried, distortion of the frame should not be possible, even if the frame itself was made more rigid than at present. But one thing is quite certain: unless all the moving parts, engine, gear, and axles, are mechanically constructed at the outset, and equally well set out on the *chassis*, no car so built will prove other than a failure and a disappointment.



Track Racing in America. Drying a Wet Track by Burning Petrol on it. [*Motor Age.*

MESSRS. PETO AND RADFORD, LIMITED, have purchased the business of Messrs. Sutherland and Marcuson, makers of the "Umpire" accumulators, and intend to carry on the business at 61, Chandos-street, Strand, W., where a stock of their own electric ignition accessories will also be kept, as a convenience to the trade in the West End and vicinity.

In the recent Dutch Military Manœuvres a number of Peugeot cars were used. The above illustration shows the vehicles lined up in the Market Square at Eindhoven.

SOME USEFUL NOTES.

AFTER a car has been in continual use for some time, it is not a bad plan to thoroughly overhaul the cooling system, wash out the water tank and the jackets, and thoroughly cleanse the pipes and coils by means of a hose. It is astonishing what a lot of dirt accumulates after a season of continual use.

ALWAYS carry a lamp showing a good red light on the back of the car, on the right side facing in the direction of forward motion. This red light may prevent another driver from running a car into yours from behind. When stopping on the road at night for repairs, or other causes, move the car as much as possible to the left side of the road, and see that the rear lamp shows clear and bright.

SOMETIMES it happens that the piston-rings of a petrol motor work round until the slits in them are opposite one another. When this occurs there is sudden loss of compression. The remedy consists in injecting a few drops of paraffin oil into the cylinder while the engine is running. One or more of the rings will work round after a time and compression will be restored.

WHEN an engine has been running for a short time after paraffin has been injected into the cylinder a reddish deposit will be found on the plug which may interfere with the firing. This is sometimes ascribed to over-lubrication, but is in reality due to the paraffin.

EVERY intending purchaser of a car should insist on the fitting of a petrol gauge, if no provision is made for easily estimating the quantity present in the tank. How often have we seen drivers worried by the uncertainty of having sufficient petrol left to carry the car to its destination, and compelled to make some crude measurement by means of a stick thrust into the tank, at the imminent risk of contaminating the spirit, or driven to the necessity of making a rough and frequently inaccurate calculation based on mileage covered and average consumption of engine.

ALTHOUGH a plug in which the packing is loose may yield a good spark when the car is standing at rest, the current may be short-circuited in the plug under the influence of vibration when the engine is running, and misfires result.

THE experienced motorist does not start his motor until he is ready to actually commence his journey, nor does he allow it to run idle except when stopping but a very few minutes. Some makers consider that running idle is harder on the motor than running under load; but, be this as it may, it cannot do the mechanism any good, and shortens the life of the bearings. Above all, the motor should not be allowed to race, or run at an abnormally high speed without load, as overheating will soon result, in addition to the severe racking.

TO those who have recently joined the ranks of motorists the advice may be given that it is well to train the ear to be on the alert for any variation from the usual sounds made by the motor and transmission mechanism. Every sound indicates something—either that the source from which it proceeds is doing its work under normal conditions, or that something is wrong. A motor rarely stops without giving warning, and an unusual noise should be heeded at once. It may indicate an incipient evil that can be readily cured in a few moments, but which, if neglected, may develop and spread and run into time and money. It is generally the motorist who knows his car intimately and knows the meaning of every sound and every vibration who gets through a season with but few stoppages and a small repair bill.

IF a Michelin valve leaks in spite of the tight screwing-up of the dustcap, remove the central wire of the valve and apply a little grease to its conical rubber extremity. In most cases this will establish a permanent cure.

HERE AND THERE.

A MOTOR-OMNIBUS service has just been started between Utrecht and Harmelen, Holland.

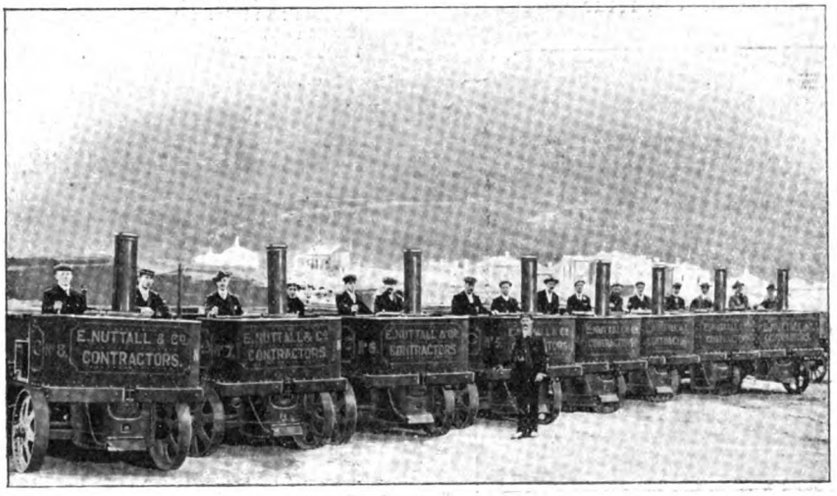
THE Express Cycle and Motor Works have an extensive motor garage in the Stockport Road, Manchester.

A GRAND prize, taking the form of a banner, has been awarded to the White steam car at the St. Louis Exhibition.

A SERVICE of motor-'buses between Horncastle and Spilsby has been suggested by a correspondent familiar with the district.

THE Duryea Power Company has received a bronze medal for its exhibit of Duryea Power carriages at the St. Louis Exhibition.

THE balance-sheet of Messrs. A. Darracq and Company, Limited, shows a net profit of £112,213 for the past year. An extension of the works at Suresnes has been decided upon.



AT Nottingham, Messrs. A. R. Atkey and Company are erecting a new motor garage in Trent Street, and Messrs. C. Binks and Company have a similar establishment in Goldsmith Street.

A MOTOR CAR is about to be purchased by the Chicago Public Library for delivery purposes. Some tests were recently made, and it was found that an automobile did the work of two horse-drawn vehicles in half the time occupied by the latter.

MESSRS. GLOVER BROS., LIMITED, van builders, Cleveland Street, London, W., are introducing a new petrol lorry designed to carry loads up to three tons.

THE LONDON MOTOR GARAGE COMPANY, LIMITED, inform us that they keep a stock of the Beau non-skidding bands described in a recent issue of the *Journal*.

MR. ALBERT E. NEWTON, who was compelled, owing to pressure of business, to resign the hon. secretaryship of the Reading Automobile Club, has taken over the management of the Automobile Lubricants Department of the Vacuum Oil Company, Limited.

A Group of eight "Colonial" Steam Tip Wagons recently supplied by the Lancashire Steam Motor Company, Ltd., to Messrs. E. Nuttall and Co., Contractors, Cape Town.

MOTORISTS have been using the cycle track on the Esplanade at Dundee, and reference to the matter was made by Mr. David Mathers at a meeting of the Works Committee of Dundee Town Council. The members were all of opinion that such could not be allowed in the future, as the practice was objectionable and unsafe. The subject was remitted to a sub committee for their consideration.

THE White Steam Car Company have sent us a copy of No. 7 of their bulletin, which contains an interesting illustrated account of the part played by White steam cars in the recently concluded manœuvres of the United States Army in Virginia, and the New York-St. Louis automobile tour, organised by the American Automobile Association, which took place in the months of July and August last.

MR. MAX PEMBERTON, the well-known author, has ordered a 16-20-h.p. Brooke car. The illustration on another page shows him at the wheel of one of these vehicles with testing body. The other Saturday afternoon this particular car was driven from the works of Messrs. Brooke at Lowestoft, never having been run before, to Cambridge and back, a distance of nearly ninety miles, without a single adjustment or alteration of any kind whatever and was handed over directly to the coach-builder.

SIR A. CONAN DOYLE is among the latest additions to the ranks of motor-cyclists.

THE motor-'bus service from Knott End to Pilling, Lancashire, has been discontinued for the winter season.

THE Marquis of Anglesey's Pullman motor-car has been bought by Mr. Ramsden, of Middleton Tower, Norfolk.

THE Collier Tyre Company held an inaugural luncheon at their new premises, 127 to 130, Long Acre, W.C., on Wednesday.

A NEW fire engine fitted with a 30-h.p. four-cylinder petrol motor has been supplied to the Finchley Urban District Council Fire Brigade.

MESSRS. A. and C. PAYNE, of the Queen's Motor Works, Queen's Road, Peckham, S.E., are letting cars on hire and have every facility for the repair of vehicles.

CAPTAIN DEASY and Mr. E. G. Williams are continuing the even tenour of their way on the Martini car now engaged on its 4,000 mile run. So far the vehicle has behaved so uniformly well that there are no incidents to record.

MESSRS. DELAMOTTE AND FOSTER, of Birkbeck Bank Chambers, London, W.C., have been appointed representatives in Great Britain and Ireland of the Société des Usines Prunel. They are making a speciality of motor-car *chassis* ranging from 9-h.p. to 24-30-h.p., these being fitted with either Prunel or other standard engines.

THE automobile school of the West Side Y.M.C.A., New York, was officially opened on the 9th inst. The class numbers 136 students, some of whom are owners of cars.

DR. ORMANBY, of Messrs. Crossfield and Son, Warrington, has given evidence this week before the committee appointed to inquire into the use of duty-free alcohol for industrial purposes.

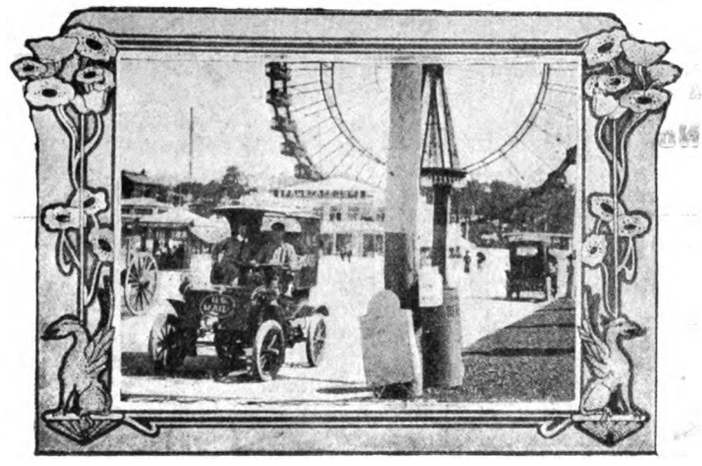
MUCH excitement prevailed at the Empire City track, New York, on the 8th inst., when Kulick, on a 20-h.p. Ford car, covered five miles in 4 min. 48 2 5 sec., beating Bernin, on a 60-h.p. Renault, and Sartori, on a 90-h.p. Fiat.

AMONG new motor services contemplated by the Great Western Railway Company for next season is one from Newquay to Truro station, and from Truro station to Malpas.

MESSRS. A. DARRACQ AND CO., LIMITED, are sending out to India, for the reliability run from Delhi to Bombay, two Darracq cars of 15 and 30 h.p. Mr. E. J. Robertson-Grant has sailed from Liverpool with a 12-h.p. Argyll car, which he will drive in the Indian races.

IN order to meet the requirements of increasing trade, Messrs. Hodson and Co., Limited, have removed into more commodious premises at 20, Lytton Street, Everton Road, Liverpool, where they have added a department for motor-cars. Facilities have been obtained for executing any kind of repairs, and also for cleaning and storing cars, as well as supplying petrol, etc.

THE Automobile Mutual Protection have instructed Mr. Shrapnell Smith, F.C.S., M.R. San Inst., M. Soc. Chem. Ind., to represent them before the Committee appointed by the Chancellor of the Exchequer to enquire into the use of duty-free alcohol for industrial purposes. Mr. Shrapnell Smith advocated the use of alcohol in an address to the Lincolnshire Automobile Club more than two years ago, and his training as a chemical engineer should stand him in good stead in giving helpful evidence before the Committee.



Digitized by Google

THE two Oldsmobiles which recently made such a creditable tour of the country were fitted with the Fisk detachable tyres. Despite the severe weather and the bad stretches of road which were met, only two punctures occurred, these being on each of the hind tyres on the big car.

FROM the Lancashire Steam Motor Company, Limited, Leyland, comes a copy of their new catalogue of steam-wagons, which includes full page illustrations of the different types of vehicles turned out. Particulars are also given as to the cost of upkeep of the wagons and also of the company's "composite" and "colonial" road wheels.

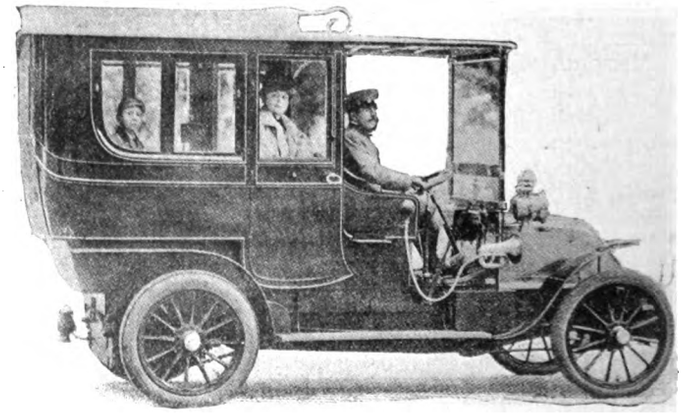
MR. STANLEY W. ANDREWS, the patentee of the "Stanley" silencer, has just returned from Belgium after having appointed M. C. Meuffels, of 59, Rue des Vennes, Liege, the sole manufacturing agent for that country. The improved form of silencer known as the "Stanley Perfect" is, we understand, to be placed on the market at an early date.

A 6-H.P. motor-car is making a record for itself in the postal service at the St. Louis Exhibition as compared with the horse service. One automobile and one horse are employed to gather and distribute letters at the Exhibition. With the former six daily collections are made through the Plateau of States and the part of the grounds which includes all the exhibit palaces. In the morning, at eight o'clock, the motor-car takes carriers to the several points where they begin distribution. Four men are carried on the first trip and three on the second. This occupies half an hour. At 8.30 the car, returning from its

second trip, stops for the first collection at the Inside Inn. The automobile conveys 800 letters to this place at each delivery five times a day. Each motor-car collection through the grounds requires from fifty minutes to an hour, there being fifty boxes on the route.

THE Advance Motor Starter Company, Limited, has been registered, with a capital of £1,500, to acquire the business carried on at 185, Princess-street, Manchester, as the Advance Motor Starter Company, and to adopt an agreement between Messrs. U. Horsfall and J. Crowther of the first part, Mr. A. G. Brown of the second part, and this company of the third part.

DIARIES and calendars from Messrs. T. de la Rue and Co., Limited, remind us of the ending of the year and the need for thinking of portable diaries and the like for 1905. This firm has introduced a useful series of upright date cases, engagement cases, and the like, while their well bound and nicely arranged diaries are models of condensation and neatness. Their "handy" series is a charming assortment of booklets for ladies' use.



MESSRS. COXETER AND SONS, LIMITED, Abingdon-on-Thames, have sent us a photograph of a useful little accessory they have lately introduced. It consists of a small box intended to be mounted on motor dash-boards or the fronts of canopies The box is made of mahogany, dovetailed and polished, with pull-out bottom drawers and hinged-top lid, suitable for maps, gloves, small tools in the top box, and cigarettes, papers, tobacco and matches in the bottom drawer. The dimensions of the box are:—Depth 7 in., width, back to front, 3½ in., and length 12 in.

AN order for a 22-h.p. Crossley motor-brougham has just been placed with Messrs. Jarrott and Letts, Limited, by Lady Alwyne Compton. The carriage work is being built by Messrs. Rothschild and Co., of London, and will be of a most luxurious description.

The above illustration depicts a 12-h.p. Duryea Dog-cart Phaeton lately sent out to Selangor, Straits Settlements. The car is fitted with double fuel tank and Cremorne carburettor arranged to run on either petrol or kerosene at will. The front wheels are shod with Collier pneumatics, and the back with De Nevers solids.

AT a recent meeting of the Manchester Literary and Philosophical Society, Dr. W. A. Bone read a paper on "The Mode of Combustion of Hydrocarbons." In it he gave an account of researches carried out by himself, in conjunction with Messrs. R. V. Wheeler and W. E. Stockings, at Owens College, on the slow combustion of hydrocarbons below their ignition points. The older theories that in a defective oxygen supply either the hydrogen or the carbon is preferentially burned are shown to be based on misrepresentations of the facts, and must be abandoned. The authors' results led them to conclude that when a hydrocarbon is burned in well-defined stages, oxygen initially enters the hydrocarbon and is distributed between the carbon and hydrogen, giving rise to unstable hydroxylated molecules, which, sooner or later, according to the rapidity of the process, undergo thermal decompositions into simple products. It is therefore necessary carefully to distinguish between the purely chemical and the thermochemical changes which occur during combustion.

Madame Rejane, the well-known French actress, in her 15-h.p. C.G.V. Limousine, which is superbly fitted up as a saloon, and can be converted into a sleeping compartment.

THE Isle of Wight Express Motor Syndicate, Limited, has been registered with a capital of £10,000 to provide an express motor-omnibus and parcel service in the Isle of Wight. The first directors are Sir A. Onslow, Mr. A. G. Millward, Lieut-Colonel Hamilton, Mr. A. Angrove, and Mr. C. C. Macklin. The registered offices are at Market Street, Ryde.

THE STANLEY SHOW.

—◆—

During the week the Stanley show has been in progress at the Agricultural Hall, London, the attendance of the trade and agents again testifying to the popularity of that familiar place for such displays. The feature of the show is undoubtedly the large number of tri-cars, some of which are sufficiently similar in design to the Bollée of eight or nine years ago to warrant the suggestion that they are really a "revival," rather than an innovation. The illustration on page 804 is reproduced from "Industries and Iron"—the immediate predecessor of the *Motor-Car Journal*, which thus sustained its continuity with the "Mechanics' Magazine" of the early years of last century—of 1896.

Pressure of space prevents the completion of our report this week, and we have been compelled to hold over reference to several novelties to our next issue.

The Siddeley Autocar Company display three different types of cars. First we find a *chassis* and complete vehicle of the popular 6-h.p. Siddeley two-seater, which has already been illustrated in the *Journal*. The engine is of the single-cylinder horizontal type, 4½ in. bore, by 5 in. stroke. Three speeds and a reverse are provided, the transmission throughout being by means of chains. Fig. 1 illustrates a handsome 12-h.p. landaulet with Mulliner body. The engine is of the vertical type, comprising two cylinders, 4½ in. diameter by 4½ in. stroke; the inlets and exhaust valves are mechanically operated, the former being provided with a variable lift device by which the speed can be regulated. Four speeds and a reverse are provided, the transmission being by side chains. The finish both of the *chassis* and the body is of an excellent character, and although only a double-cylinder, the car is unusually quiet in operation. A side-entrance double phaeton on a 12-h.p. *chassis* is also to be seen, as well as one of 18-h.p., the latter being similar to the 12-h.p., except that the engine has four cylinders. In order that motorists may inspect the quality of the workmanship, specimens of the engines, gear boxes, etc., fitted to the Siddeley cars are included in the exhibit.

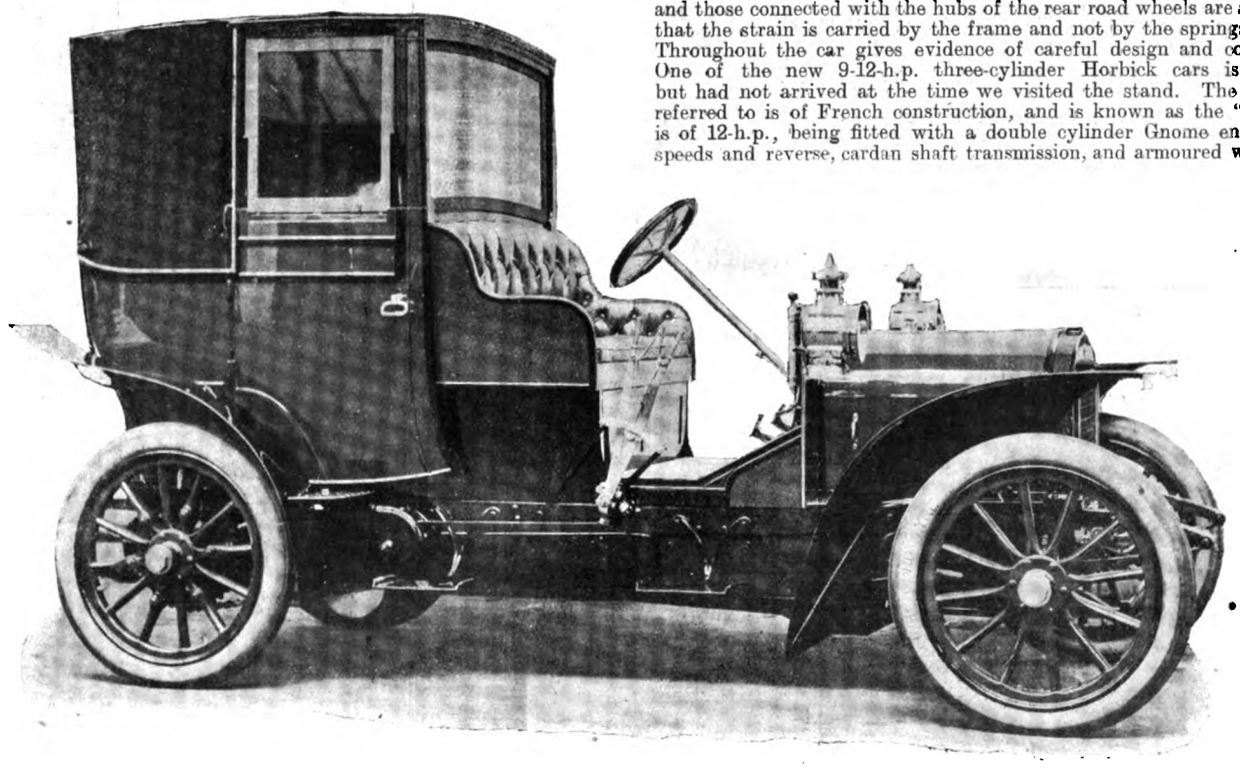

Fig. 1.—The Siddeley 12-h.p. Landaulet.

The East London Rubber Co. have on view a new two-seated motor-car known as the Kerry. This is on standard lines, having a tubular frame, and 8-h.p. double-cylinder engine with mechanically-operated inlet valves. The water circulation is maintained by a friction-driven pump and a radiator with draught-inducing fan. Three speeds and a reverse are provided, the drive from the gear-box being by means of a cardan shaft and bevel gear on to a live axle. The car appears to be of sound construction, ample accommodation being provided for two passengers and a large amount of luggage.

The Crypto Car and Cycle Co., in addition to a neat motor-bicycle fitted with a 4-h.p. Antoine engine, have on view a complete 8-h.p. *chassis*, representing one of a series they are supplying to carriage builders and others, who may fit their own bodies thereto. The frame is of wood and steel construction, while the engine, set forward as usual, is an 8-h.p. De Dion. Three speeds and a reverse with a direct drive on top speed are provided, the power being conveyed to a rear live axle by a cardan shaft and bevel gear. The brakes are all of the metal-to-metal expanding type. On the same stand is to be seen a big display of motor-car components, a new sparking plug with steatite insulating material, the Parsons non-skid device, and a range of Crypto accumulator charging dynamos.

The Regal Motor Car and Launch Co., Limited, exhibit several Regal cars, including a two-seater with 6½-h.p. De Dion engine; a 12-14-h.p. tonneau,, with Aster motor, a 16-20-h.p. landaulet, with Brouhot engine, and a 24-h.p. tonneau with Mutel motor. All the cars are of the live axle type, being driven through a cardan shaft and bevel gear.

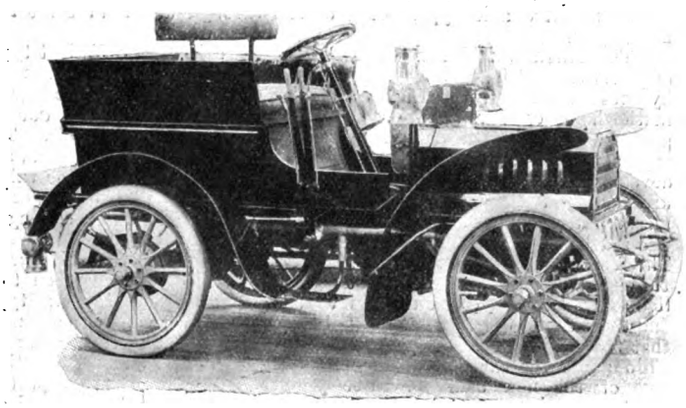
The Britannia Motor Garage, Limited, exhibit two distinct types of petrol cars. The first we examined was one of the Horbick cars made by Messrs. Horsfall and Bickham, for whom they are now the agents in the home counties. The vehicle is of 15-20-h.p., and has a double-phaeton side entrance body mounted on a pressed steel frame. The engine comprises four cylinders, 90 mm. diameter by 105 mm. stroke, and develops 21 b.h.p. at a speed of 1,200 revolutions per minute. The valves are all on one side of the engine, both the inlets and exhausts being mechanically operated off a single cam shaft. The water cooling is effected by a friction-driven pump and a honeycomb radiator and fan. Three speeds and a reverse are controlled by one lever, the drive being through a leather-faced internal cone clutch and cardan shaft on to a live axle. The brakes are of the internal expanding metal-to-metal type, and those connected with the hubs of the rear road wheels are so arranged that the strain is carried by the frame and not by the springs, as usual. Throughout the car gives evidence of careful design and construction. One of the new 9-12-h.p. three-cylinder Horbick cars is expected, but had not arrived at the time we visited the stand. The second car referred to is of French construction, and is known as the "J. P." It is of 12-h.p., being fitted with a double cylinder Gnome engine, three speeds and reverse, cardan shaft transmission, and armoured wood frame. The valves of the motor are mechanically actuated, and the mixture is furnished by an automatic carburettor. The wheel base is 8 ft. 6 in., enabling a roomy side entrance double phaeton body to be fitted. On this stand the Thor Motor Car Co. exhibit one of their 6-8-h.p. two-seated cars, of which a description was given in the *Journal* of October 15th. A leading characteristic of this vehicle is the method of suspension, which enables solid tyres to be used in place of pneumatics.

Messrs. Watson and Oliver, Ashford, Middlesex, display an interesting tri-car, known as the Greyhound. It is fitted with a 3½-h.p. engine, with Oppermann three-speed gear and clutch, chain drive, and a specially-designed frame, with particularly comfortable seating for both passenger and driver. They also show the Greyhound tri-car fitted with 3-h.p. Fafnir engine and Bowden two-speed hub, bucket seat for driver, comfortable footboard, special boxes for tools, etc. An ingenious three-wheel runabout for a single passenger is displayed by Messrs. Jackson and Kinnings, of Southport. It is known as the Ribble, and is built on the lines of a car. The motive power is supplied by a 8-h.p. M.M.C. engine with mechanically-actuated inlet valves; it is water-cooled on the thermo-siphon system by means of a combined tank and framed radiator set in the front of the frame. Two speeds are provided, the power being transmitted by a chain to a countershaft on which is mounted a two-speed gear, each being provided with its own chain connecting it with the rear road wheel. Steering is controlled by an inclined hand wheel, on which the control levers are mounted. Both

Digitized by Google

foot and hand-operated band brakes are provided. The makers claim that under favourable conditions this machine is capable of attaining a speed of 50 miles an hour. A somewhat similar machine, but arranged for two passengers, is also shown. This has a 4½-h.p. motor, with a radiator arranged under the footboard of the front seat. Steering is controlled by a wheel, and the transmission is by chains, two speeds being provided.

Fig. 2 depicts the attractive little Jackson dog-cart exhibited by Messrs. JACKSON and COMPANY, which has been improved in many of the details for the 1905 season. The motor is a 6½-h.p. single-cylinder De Dion. The power is transmitted to the rear wheels through a clutch,



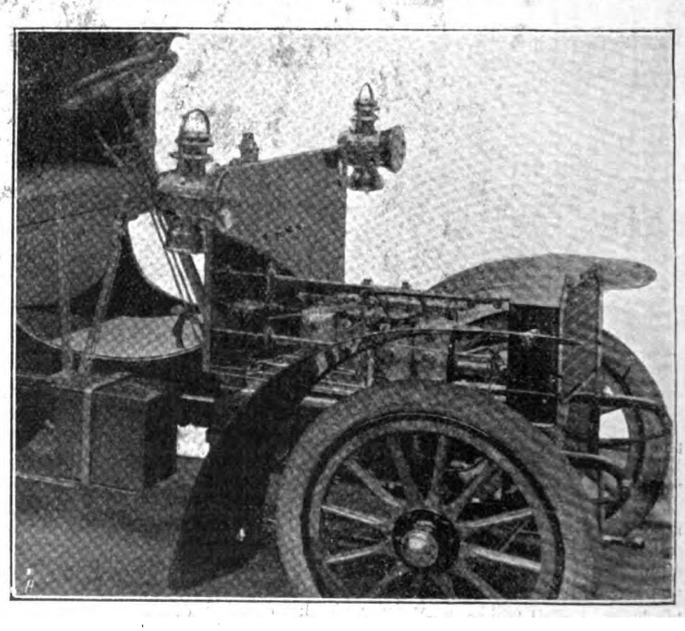


Fig. 2.—The Jackson Dogcart.

gear-box, giving two speeds and one reverse, with direct drive on top speed, by a cardan shaft and bevel gear to the rear live axle. The frame is of tubular construction strengthened by a superimposed auxiliary armoured wooden frame. The water-circulating pump is driven by friction off the fly-wheel. Pneumatic or De Nevers solid tyres are fitted to the artillery type road wheels, which run on ball bearings. A feature of the car is the ease with which the whole body can be detached from the frame, enabling all parts of the transmission to be easily reached when adjustments are necessary. The car, which is exceedingly moderate in price, is arranged to carry four persons, or the back seat may be folded up to form a touring car with two persons, with ample accommodation for luggage.

The exhibit of Messrs. J. A. PRESTWICH AND CO., of Tottenham, is attracting notice by reason of the somewhat novel tri-car shown. It is known as the Dual car, the two seats being placed side by side. The engine is of the air-cooled type, of 4½-h.p., with the inlet and exhaust valves on the top of the cylinder head and mechanically-actuated by a single rod; it is placed at the extreme front of the machine, and a special clutch is fitted on the engine shaft. The latter consists of a number of circular discs made in two sizes, the smaller having square holes, and fitted on a square shaft; the larger discs have round holes, which clear the square; they are, however, provided with notches on their edges, into which engage ribbed projections on the clutch casing. The discs are pressed together by a pedal-operated spring which causes the plate to grip and lock the clutch. The transmission from the latter is by means of a long shaft and a roller-worm drive, for which a high efficiency is claimed. On the hub of the rear wheel is mounted a small wheel, carrying a number of radial pins, on which revolve conical rollers. These rollers engage with a hardened steel worm, which is cut in such a manner that they bear on the worm all the time they are in gear. Wheel steering is provided, the control levers being mounted on the wheel. A hand lever actuates a band brake on the rear wheel, while a foot lever operates two front wheel brakes. A well-designed tri-car is shown by the MARS MOTOR AND CYCLE CO., LIMITED, Finchley. This is fitted with a 4-h.p. White and Poppe motor, with water circulation by a belt-driven pump. The front wheels are covered by large steel wings with leather flaps on the inside to protect the rider from mud. The front is fitted with a coach-built body, and the back rider has a coach-built bucket seat. The transmission is by chains through a neat form of friction clutch and two-speed gear.

The chief object of interest at the stand of Messrs. A. DARRACQ AND CO., LIMITED, is the new model of 8-h.p. car which is being introduced for the 1905 season. The one on view is fitted as a four-seated car, with tonneau body, but it is also supplied as a two-seater. The vehicle has a pressed steel frame, in the forward part of which is set an 8-h.p. single-cylinder engine 112 mm. bore by 120 mm. stroke. The inlet valve is mechanically operated, and is provided with a device in conjunction with the governor whereby its lift, and consequently the speed of the engine, can be regulated. The water circulation is maintained by a pump driven off the half-speed shaft. The power is transmitted through the clutch to the change speed gear-box, which is adapted to give three forward speeds and a reverse controlled by, as usual in Darracq practice, a lever on the steering column. On the top speed the drive is direct through the cardan shaft and bevel gear to the live axle. The brakes are of the metal-to-metal type. There are a number of detailed improvements in the car, among which may be mentioned the fitting of side panels to the front mudguards, which prevent the splashing of mud on to the front wheels. The exhibit also includes a 30-h.p. four-cylinder *chassis*, and examples of the 12-h.p. and 15-h.p. cars, among the latter being a handsome landaulet. The vehicles are on similar lines to the 1904 models, but comprise a number of changes in detail. Among these are the adoption of forged steel axles of H section. The steering column is now sloped considerably more, and magneto ignition can be fitted at the option of the purchaser, either alone or as a secondary ignition. The brakes are of the very latest design, being internal expanding, metal-to-metal, and holding equally backwards and forwards. A new type of governor has been adopted, working on an eccentric controlled by hand and foot, and an improved form of pump is being used which makes it impossible for the water to leak, and at the same time is much more efficient than previous patterns.

The centre of attraction at the stand of Messrs. HUMBER, LIMITED, Beeston and Coventry, is the new 8-10-h.p. three-seated car, introduced to meet the demand for a four-cylinder vehicle at a popular price. The frame is, as usual in Humber practice, of tubular construction As will be seen from Fig. 3 the four cylinders are cast separately; they are 3 in. diameter by 3 in. stroke. The normal speed is 1,200 revolutions per minute, but at 1,500 revolutions the engine has been tested to develope 10·3-h.p. The inlet valves are located over the exhaust valves and are readily accessible. To take out an inlet valve it is only necessary to remove one nut and swing round the inlet pipe. The water circulation is maintained by a chain-driven pump and a combined tank and radiator with draught-inducing fan. The ignition is by coil and accumulators, the contact-maker being arranged at the side of the motor. The ignition wires are short and neatly arranged, a flexible connection being obtained between the ends of the wires and the sparking plugs by the use of short pieces of link chain. A governor is provided, this acting on a throttle on the inlet; an accelerator pedal is also fitted, as also a hand-operated throttle lever acting on the carburettor. The clutch is of the leather-faced cone type, of aluminium, arranged to give a gradual engagement. Three speeds and a reverse are provided, with direct drive on the top speed, the transmission being by a cardan shaft on to a live axle. The steering-wheel is adjustable as to height, while the hand-brake lever is of the pull-up type. The car complete weighs about 11 cwt. and has a long wheel base—6 ft. 8 in. The body is comfortably upholstered, and side-doors are fitted to the front seat. Altogether the new model is an interesting production, likely to meet with a large adoption at the hands of motorists. We understand that one of these 8-10-h.p. cars, fitted with a van body, is at present being experimentally tried by the G.P.O. authorities in London. On this stand are also to be seen examples of the Humber 6½-h.p. single-cylinder two-seated car, a 7½-h.p.

g. 3.—View of Engine of Humber 8-10-h.p. Four-Cylinder Car.

double-cylinder vehicle, with hood and front glass, similar to the one which competed in the Small Car Trials, and a 10-12-h.p. twin-cylinder car with side-entrance double phaeton body. In the tri-car section the Humber Company introduce a novelty in the "Olympia," in which the two riders sit one behind the other. The engine, of 5-h.p., is located under the rear seat, which is so fitted that it can be readily removed. The water circulation is maintained by a pump and radiator. A clutch and two speeds are provided, the transmission being by chains. Steering is controlled by an inclined hand wheel, and both foot and hand brakes are provided. Special attention has been devoted to the support of the seats, which are mounted on springs to reduce vibration to a minimum

Digitized by Google

the vehicle having both a comfortable and speedy appearance. A tri-car fitted with a 4½-h.p. water-cooled engine is also exhibited.

Interest in the exhibit of the STAR ENGINEERING Co. is largely centred in the new 10-h.p. four-cylinder Star car, which was only completed in time for the Show, the body work even now being not quite finished. The car is largely on Mercedes lines, the frame being of pressed steel. The four cylinders are cast in two pairs, the cylinder dimensions being 3 in. bore by 4 in. stroke. The inlet valves are located in the cylinder head, and are mechanically actuated off a cam shaft which also works the exhaust valves. The cam shaft is enclosed, but is so arranged that it can be withdrawn by removing four nuts. The water circulation is maintained by a gear-driven pump and a honeycomb radiator. No fan is used, the fly-wheel instead having its arms so formed as to act as a fan to draw a current of air through the cooler. The ignition is by means of a gear-driven magneto; the governor, which is mounted on the ignition tappet shaft, is adapted to act on the inlet. The power is transmitted through a leather-faced internal cone clutch to a gear box giving three speeds and a reverse and a direct drive on the top speed to the countershaft, from which the power is transmitted to the road wheels by side chains. The hub brakes are of the metal-to-metal expanding type, controlled by a pull-up hand lever; a push pedal actuates a metal contracting brake on the cross shaft. The control levers are mounted on top of the steering wheel, as in all modern large cars, while other features of note are the fitting of ball bearings in the gear-box, the countershaft brackets, and to the road wheels. The latter are 810 mm. diameter, shod with 90 mm. pneumatics. The car is built low, with long springs, and is equipped with a neat tonneau body. Altogether the Star Co. are to be congratulated on the production of the popular Talbot cars, which for the coming season are being offered at considerably lower prices than have hitherto ruled. A noticeable feature of the new models is the abolition of the automatic governor, the speed of the engine being controlled by a pedal-operated throttle and a device working in conjunction with the clutch pedal whereby when the clutch is withdrawn the speed of the motor is also cut down. We first inspected the new 10-12-h.p. car; this has a pressed steel frame and a double-cylinder engine, 106 mm. bore by 120 mm. stroke, developing its power at a speed of 1,000 revolutions per minute. The valves are all mechanically-actuated and interchangeable. The water circulation is maintained by a pump gear driven off the half-speed shaft, and a honeycomb radiator with fan. For the ignition a new type of high tension magneto working with ordinary sparking plugs is being employed. In conjunction with it is an ingenious yet simple contact maker, having a single contact blade. The ignition is controlled by a small lever on the inclined steering wheel. The power is transmitted through a leather-faced cone clutch to a gear-box, giving three speeds and a reverse, with direct drive on the top speed. A cardan shaft and bevel gear connects the gear-box with the rear live axle. The brakes are of the internal expanding type, and entirely protected from dust and mud. A comfortable form of body for four passengers is provided, the rear tonneau being detachable. The 12-16-h.p. car has a four-cylinder engine, the cylinders being separate and each 85 mm. bore by 120 mm. stroke. The general arrangement is similar to the 10-12-h.p. vehicle, but four speeds are provided, and the *chassis* is of such a length as to allow of a very roomy side entrance double phaeton body to be fitted, with ample luggage space at the rear. A new model is to be seen in the 35-50-h.p. car, the engine having four cylinders, 120 mm. bore by 140 mm. stroke.

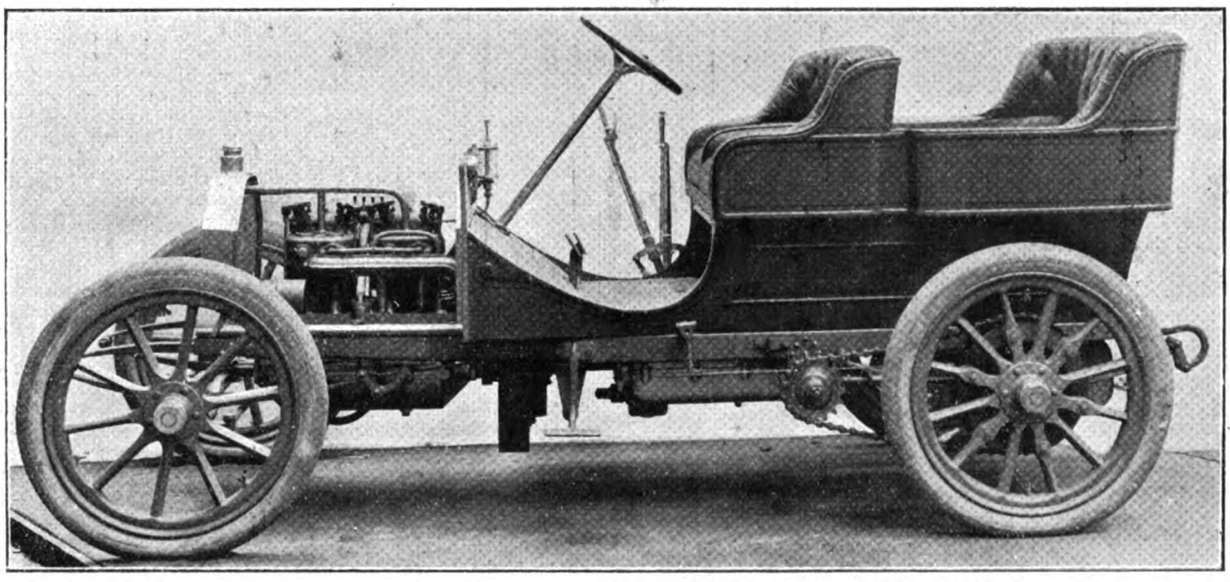

Fig. 4.—The Star 10-h.p. Four-Cylinder Car with Bonnet removed to Show Engine.

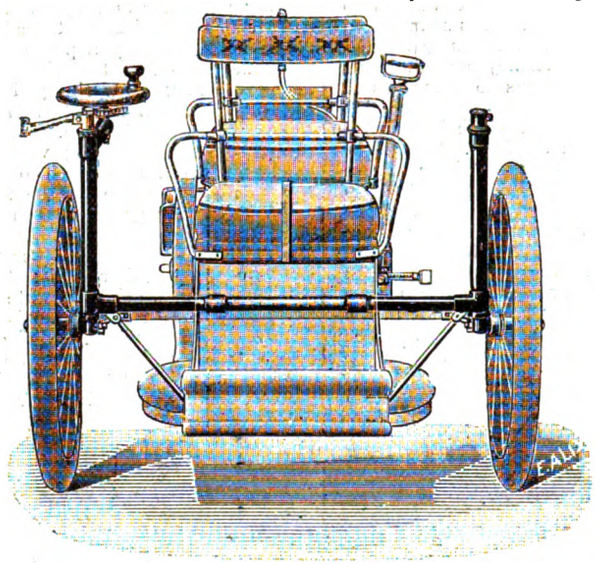
of the vehicle. Several examples of the popular 7-h.p. double-cylinder Star car are to be seen, including a *chassis*, enabling the various details to be inspected. The cylinders are 3½ in. diameter by 4½ in. stroke. Three speeds and a reverse are provided, the transmission being by means of side chains. In addition to one of the standard two-seated cars, painted red and upholstered in leather, are to be seen a three-seated car, painted cream, and fitted with a Cape cart hood, and a Victoria, painted blue, and provided with hood and front glass, this being eminently suitable for the use of doctors.

At the stand of Messrs. BROWN BROS., LIMITED, is to be seen an example of the latest type of Brown 8-10-h.p. car. This has a frame of wood and steel, in the fore part of which is set a twin cylinder engine, 90 mm. bore by 110 mm. stroke, and running at a normal speed of 1,000 revolutions per minute. The inlet valves are mechanically actuated off the same shaft as the exhaust valves; they are provided with a variable lift device, so connected with the clutch pedal that as the clutch is withdrawn the speed of the engine is cut down. The various control levers are mounted on the inclined steering wheel. Three speeds and a reverse are provided, the drive on the top speed being direct on to the live axle. The latter is enclosed in a casing, on which the rear road wheels are mounted, the power being conveyed to the latter through jaw clutches on the ends of the axle. The brakes are of the metal-to-metal type. A two-seated body, with ample luggage space, is provided, rendering the car eminently suitable for touring purposes. Great attention appears to have been devoted to the details, especially to the bearings and the lubrication of the same.

Messrs. CLEMENT TALBOT, LIMITED, have on view several new types Four speeds and a reverse are provided by a gear of the sliding pinion type, the transmission in this case being by means of side chains. For the man of moderate means an 8-9-h.p. car, with detachable tonneau body, has been introduced. This has a pressed steel frame, and a double-cylinder engine 85 mm. bore by 100 mm. stroke. The ignition is by high-tension magneto as on the larger cars, and the water-cooling and controlling arrangements are on similar lines. This is a very attractive model, and should become a popular type in the 1905 season. Finally, we may refer to an example of the 7-8-h.p. double-cylinder tonneau car with accumulator ignition, which has proved so successful during the past season.

A well-finished tri-car is included in the exhibit of the CENTAUR CYCLE Co., LIMITED. It is fitted with a 5-h.p. water-cooled engine. The water circulation is maintained by a chain-driven pump and a radiator under the front seat. The transmission of power is by a single chain to the driving wheel. Chain transmission is adopted, the machine having a two-speed gear and clutch contained in an extension of the crank case, both controlled by one lever.

Messrs. BAYLISS, THOMAS AND Co., LIMITED, is another concern exhibiting a tri-car on the lines of a small car, being fitted with wheel steering and coach-built front and rear seats. It is fitted with a 4½-h.p. engine, water-cooled by means of a gear-driven pump and a radiator. A friction clutch and two-speed gear are provided, the transmission being by means of chains. The change speed and ignition levers are both operated from the steering column, while the Longuemare carburettor is controlled from the steering wheel. Large metal-to-metal band brakes act on the hubs of the front by means of a pedal, while the back wheel



Digitized by Google

brake is actuated by a hand lever. The footboard is "trapped" to allow of easy access to the gear-box and for the adjustment of the chains. The driver is accommodated with an aluminium bucket seat, supported on elliptical springs, while the forecarriage is mounted on C springs.

Messrs. BRADBURY AND CO., LIMITED, Oldham, exhibit a novelty in the shape of a tri-car, the fore part of which is fitted with a governess body, thus protecting the passenger from the wind. The engine is a 4½-h.p. single-cylinder, water-cooled, with mechanical valves. The contact maker is of the wipe type, and a Longuemare carburettor of large size is used. The machine is chain-driven, and is fitted with a free engine clutch operated by a foot lever. A spring lever operated by the left heel catches the foot lever when depressed, and keeps the clutch released. A two-speed gear-box of the De Dion type is fitted to the machine, the gear wheels running in an oil bath. The body is mounted on C springs, and the frame is carried in the front on elliptical steel springs. Two powerful hand brakes are fitted to the front wheels, and a Bowden to the back wheel. Large foot plates are fitted, so that the driver is not cramped in any one position. For steering a handle-bar is used, although wheel steering can be supplied if desired.

CHASE MOTORS, LIMITED, have on view a tri-car, with 4½-h.p. twin-cylinder air-cooled motor. It is chain-driven, and is provided with a three-speed gear, the the pinions of which are always in reach. The STAR CYCLE CO., LIMITED, in addition to a range of motor-bicycles, display a tri-car fitted with a 4½-h.p. water-cooled motor, wheel steering, chain drive, two speeds and free engine.

The stand of the BAT MOTOR MANUFACTURING CO., LIMITED, is attracting much attention, the cause being the display of the new Bat-Kar, which is a tri-car on entirely new lines. The forecarriage is coach-built, and is fitted with sides and doors, practically forming a small tonneau body for two persons. The engine is a 6½-h.p. two-cylinder Fafnir, driving through a clutch and chain on to a gear-box, giving three speeds. From the latter a single chain drives the rear road wheel. The latter is supported on special springs in such a manner as to ensure stability in rounding corners. Ample brake power is provided, while the steering is actuated by an inclined wheel on which some of the control levers are mounted.

The Bollee of 1896. The Progenitor of the Tri-car of 1904.

THE ROVER CYCLE CO., LIMITED, Coventry, make their *debut* as exhibitors of motor-cars, having on view a *chassis* and complete car of the Rover 8-h.p. vehicle, built to the designs of Mr. E. W. Lewis. As we commence a full description of this vehicle on another page, it need only be mentioned that it comprises a number of interesting features which have already met with the approval of a number of motorists. In the motor-cycle department the chief exhibit of interest is the Rover two speed motor tandem, a view of which is given in Fig. 5 The motive power is supplied by a 4-h.p. engine water cooled on the thermo-siphon system, a combined water tank and radiator being mounted in front of the steering column. From the engine the power is conveyed through a friction clutch to a small gear box giving two speeds, and thence by a second chain to the rear road wheel. The machine is steered by means of an inclined wheel as in a car, while both foot and hand controlled brakes are provided. Specimens are also shown of the Rover 3½-h.p. air-cooled belt-driven motor tandem, of the 3-h.p. chain and belt driven motor-bicycles, and of a new specially light machine; the latter is fitted in a 2½-h.p. air cooled engine, and has belt transmission. The frame of the machine is of a new design, with the idea of combining lightness with strength: the complete motor-bicycle weighs 100 lbs. It is almost unnecessary to add that the machines are all of high grade construction, special attention having been devoted to the details.

A big display is made of the Princeps motor-cycles, made by Messrs. J. E. HUTTON, LIMITED, these ranging from 2¾-h.p. single cylinder to 5-h.p. double-cylinder, with both chain and belt transmission. There are a number of interesting points in these machines. The engine runs smoothly even at slow speeds, owing to the large diameter of the fly-wheels. The piston-pin is hollow, and secured in the piston by a special method. The carburettor is a new design, the air adjustment being automatic. Another feature is the needle-valve adjustment to regulate the size of the spray, which can be adjusted from the outside without removing any part and while the engine is running. The inlet valves are also fitted with an arrangement whereby the tension of the springs can be adjusted. A number of 3½-h.p. motor-bicycles are to be seen at the stand of Messrs. A. MABON AND CO., Clerkenwell, a feature of which is the provision of a light enclosed fan for assisting the cooling of air-cooled motors.

The chief feature of interest in the motor-cycle exhibit of Messrs. HUMBER, LIMITED, is the new light machine, which turns the scale at only 72 lbs. It is fitted with a 1¾-h.p. air-cooled engine and chain drive, the cylinder dimensions being 2½-in. by 3 in. Duplex front forks are used, and, although exceedingly light, the machine appears to have been designed to have the necessary strength in the requisite parts. The Standard Humber 2-h.p. and 3-h.p. motor-bicycles are also shown. These have been improved in various details, and the weight slightly cut down. Both types are chain-driven, and on one a free-engine clutch is fitted.

For the 1905 season, the WERNER MOTORS, LIMITED, are making three sizes of motor-bicycles, viz., 2½-h.p., 3-h.p., and 3½-h.p., in which a reversion to the ordinary suction valve is noted. Among the changes that have been effected is a new method of inlet valve control, the inlet valve being opened instead of the exhaust, and the throttle simultaneously closed to avoid a back-fire. The carburettor is now placed outside the tank, and increased petrol capacity is provided. The 3½-h.p. machine is an entirely new departure. The engine has two cylinders, 55 mm. diameter by 76 mm. stroke, fitted parallel with the crank bracket. The belt system of transmission is retained. The new Werner models have an attractive appearance, the tank work being enamelled French grey with crimson lining, and the wheels and belt rim a buff colour, which does not show up dust or mud.

Although the RILEY CYCLE CO., LIMITED, show two or three tri-cars of 4½-h.p., interest at their stand is chiefly centred on the new twin-cylinder three-wheel machines for two persons. It is provided with a 6-h.p. V-shaped engine the cylinder being 80 mm. by 80 mm., the inlet valves being mechanically operated by a single cam. The motor is water-cooled, the circulation being effected by means of a pump driven by gearing direct from the engine-shaft. A Longuemare carburettor furnishes the mixture and a make-and-break contact works in connection with two accumulators, coil, and a two-way switch. The transmission is through a chain drive, two speeds and a free engine being provided, all of which are actuated by a single side lever. A metal-to-leather friction clutch is controlled by a pedal. The comfort of the passengers has been well considered, the driver being provided with a luxuriously upholstered spring seat, attached to a body carried by the frame, and which by the removal of two wing-nuts swings back on the rear axle, so giving access to the engine and gear. Three powerful band brakes are provided, the

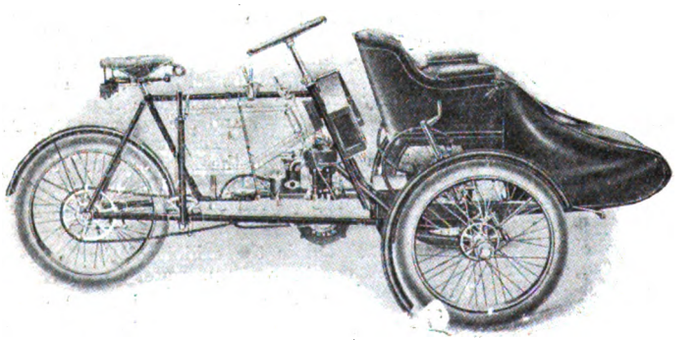


Fig. 5.—The Rover 4-h.p.-Tri-car.

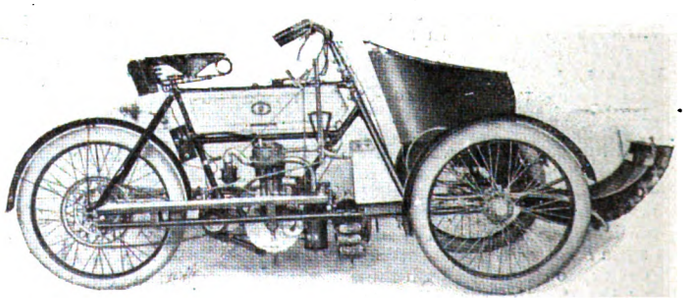

Fig. 6.—The Riley 4½-h.p. Tri-car.

Digitized by Google

front pair being manipulated by a pedal and the rear one by a side lever. Steering is by an inclined hand-wheel, on which the control levers are mounted. Altogether the new machine strikes us favourably as being both speedy and reliable.

In addition to their standard motor-bicycles, fitted with a 3¼-h.p. engine in an inclined position, Messrs. Bayliss, Thomas and Co., Limited, have now brought out a 3-h.p. Excelsior belt-driven machine, weighing 130 lbs., with the engine in a vertical position. A two-way switch is attached to the top of the frame and works in connection with two accumulators, which, with a trembler coil, are carried in a neatly-designed tank under the saddle.

The Raleigh Cycle Co., Limited, Nottingham, in addition to examples of their 3-h.p. motor-bicycles, exhibit one of their latest two-seated Raleighettes. This has a trussed girder frame, the tanks being so arranged that a lady can drive. The power is supplied by a 3½-h.p. water-cooled engine governed on the exhaust, and driving through a clutch and chains on to a two-speed gear. The machine is fitted with powerful brakes to all three wheels.

The exhibit of Mr. George A. Barnes, of Lewisham, includes a 4-h.p. motor-bicycle, a 4-h.p. single-seated three-wheel "runabout," and a 5-h.p. water-cooled two-seated fore-car; the latter is chain-driven, and is provided with two speeds. At this stand Mr. R. W. Curtis, of Holbeach, exhibits Cooke's patent cycle seat, which made its appearance at the Motor-car Exhibition in April last, and was illustrated in these columns at the time. The seat has been somewhat improved, and can be supplied with various forms of seat pillars for attachment to different types of machines.

The Quadrant motor-bicycles are shown in two sizes—2-h.p. and 3-h.p. The machines are belt-driven, and are noticeable on account of the spring front forks provided, which considerably reduces the vibration. The Quadrant Cycle Company, Limited, also have on view one of their new "Carettes." This is supplied as a two-seated machine; the front seat is, however, so made that it can be readily converted into a single-seated runabout, this latter form being illustrated in Fig. 7.

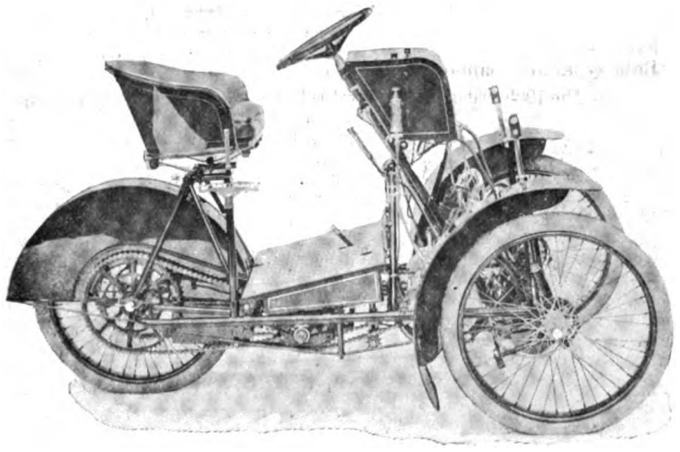

Fig. 7.—The Quadrant 5½-h.p. "Carette" without Front Seat.

The motive power is supplied by two entirely separate air-cooled engines giving together 5½-h.p., and driving by chains on to a countershaft, which in turn is connected by chains to the rear road wheel. The machine is open at the back, with spring-supported bucket seat and wheel steering, so that it can be driven by a lady, both driver and passenger being isolated from vibration and entirely shielded from mud splashings.

The new Rexette exhibited by the Rex Motor Manufacturing Co., Limited, is the latest development of the tri-car, having, however, more the appearance of a three-wheel car than a motor-cycle, and, judging from the interest which is being shown in the machine, it will apparently be a very popular type in the 1905 season. A feature is the "live" tubular frame, this being suspended by long springs on the road wheels. The motive power is supplied by a 5-h.p. water-cooled engine set a little behind the centre of the frame. The water circulation is on the thermo-siphon system, no pump being used. Two speeds are provided, and, as will be seen from the sectional illustration given in Fig. 8, the engine crank case and gear box are combined in one casting. A and C are two pinions keyed to the engine shaft T, and in constant mesh with the two gear wheels B and D on the countershaft S. On the inside of B and D are fixed jaw clutches F and H, separated by sliding jaw clutches E, J, G, which engage with either the high speed pinion D or low speed pinion B, as required. The clutch M and N is fitted at the extremity of the change speed or countershaft S. On this clutch a chain wheel K, is fixed, which imparts motion through a strong roller chain to the chain wheel on the rear road wheel. The engine is started by a handle which is always in position. Ignition is by accumulators and trembler coil. The rear band brake is 9 in. in diameter, with a 1¼ in. face, and is put into action by a side lever with notched quadrant. One pedal actuates the two front band brakes, and a second one controls the clutch. The seats, both for driver and passenger, are of larger proportions; the petrol and lubricating oil are carried beneath the front seat. Ample mudguard accommodation is provided, and the method of covering in the rear portion gives the car a striking appearance while adding greatly to the rider's comfort. One of the Rex Simplex 12-h.p.

double-cylinder tonneau cars with cardan shaft transmission is also to be seen at this stand.

The Enfield Cycle Co., Limited, which are at work on a chain-driven machine, confine their exhibit to a display of well-finished belt-driven machines fitted with a 2¼-h.p. engine having mechanically-

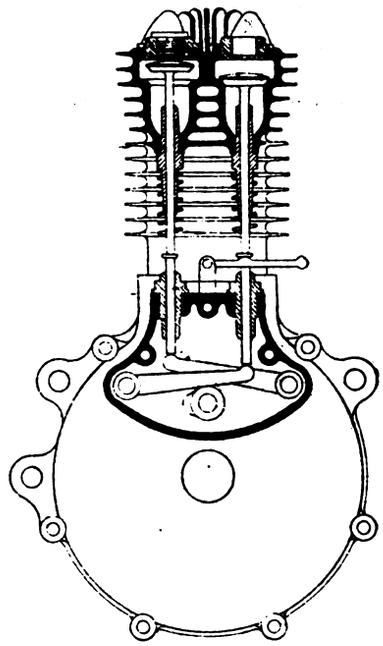

Fig. 9.—Section of Enfield 2¼-h.p. Motor-Cycle Engine.

operated inlet valves. The cylinder is 70 mm. bore by 72 mm. stroke. A sectional view of the motor is given in Fig. 9, in which the method of actuating the mechanically-operated valves by means of rocking levers working on cams is clearly shown. The mixture is furnished by a Brown and Barlow carburettor.

Digitized by Google

Messrs. Alldays and Onions, Limited, Birmingham, exhibit specimens of their 2½-h.p. and 3½-h.p. motor-bicycles in which the engine is fitted vertically on a special cradle, the power being transmitted by a V-belt to a light pulley attached to the rear wheel. A novel two-seated motor-sociable, in which the riders are seated side by side, is shown by Mr. John L. Thomas, of Barnet. This is fitted with a 3½-h.p. air-cooled engine located right in front, and transmitting its power to the rear road wheel by a flat belt. The steering is controlled by a wheel, while both foot and hand brakes are provided. The Eclipse Motor and Cycle Co., Birmingham, exhibit a number of motor-bicycles, including one fitted with a 5-h.p. double-cylinder engine, the cylinders being arranged in the form of a V. Here may also be seen the XL All puncture stops and spring terminal clips, illustrated in recent issues of the *Journal*.

One of the novelties in the motor-cycle section is to be seen at the stand of the Barry Motor Co., where is exhibited a motor-bicycle fitted with a 4-h.p. rotary petrol motor weighing only 15 lbs. In the absence of drawings it is somewhat difficult to describe the engine, which comprises two small cylinders, 2 in. diameter by 2 in. stroke, set opposite to one another in such a way that the connecting rods work on to a fixed central crank shaft. The explosive charge is not taken direct into the combustion chambers, but first of all is led into a pressure cylinder at right angles to the working cylinders, which it reaches under pressure. The silencer is arranged opposite to the pressure chamber in such a way that the whole—the two cylinders, the pressure chamber, and silencer—rotate at a speed of about 1,500 revolutions per minute. Suitable arrangements are made for the admission of the gas, ignition, lubrication, etc., while the high speed at which it rotates is stated to be sufficient to keep the engine thoroughly cool. The arrangement is certainly ingenious, but we are somewhat doubtful as to whether it can be successfully adapted to motor-cycle propulsion. The International Electrical Engineering Co. display the C.I.E. motor-bicycle, which is made in two sizes, 3 and 4-h.p. The vertically-set engines have mechanically-operated inlet valves and magneto ignition, and transmit their power by V belting.

Two sizes of the well-known Griffon motor-bicycles are shown by the Griffon Motors, Limited—2¾-h.p. and 3½-h.p. In both the belt system of driving is adopted. Among the details we noticed that an improved form of carburettor is fitted, in which an auxiliary air inlet is opened or closed automatically according to the position of the throttle lever. Examples of the Zedel motor-cycle engines are also to be seen, including the 2¾-h.p. and the 3½-h.p. single-cylinder, and a new V-shaped double-cylinder motor of 5½-h.p. The engine has cooling ribs to the head and upper part of the cylinder only. The lower part has a number of holes pierced in it, these being covered by a movable collar in which holes are also drilled, so that when the collar is turned so as to bring the holes opposite to one another, the engine can exhaust directly into the air.

One of the great novelties in the motor-cycle section of the Show is the new F.N. 3½-h.p. four-cylinder motor-bicycle exhibited by Messrs. W. R. McTaggart, Limited, and of which the first illustration in this country was given in the *Journal* last week. A general view of the machine is given in Fig. 11, while details of the transmission are shown in Fig. 10. The motor is formed of four air-cooled cylinders, 45 mm. diameter

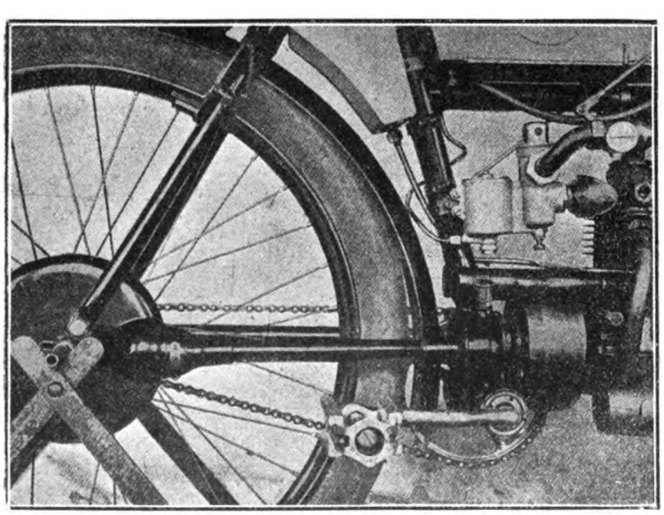

Fig. 10.—The Transmission Gear of the F.N. Four-Cylinder Motor Bicycle.

by 57 mm. stroke, fitted with automatic inlet valves and high-tension magneto ignition. The driving arrangement comprises two bevel gears, one of which is driven by the motor, and the other fixed on the rear wheel hub, both being connected together by a transmission shaft. The whole gear is protected by a dust proof case filled with grease to insure sufficient lubrication of the various parts. To avoid the shocks, due to the explosion in the motor being transmitted to the bevel gears, an elastic coupling contained within the fly wheels is interposed between them. The frame is built 22 in. high, and has a long wheel base, and a spring front fork is employed to absorb road vibration as much as possible. Two powerful brakes are fitted, while, for easy starting, an exhaust valve-lifter is provided.

Phœnix Motors, Limited, has always strongly favoured a reasonably light type of machine, and exhibit a 2-h.p. belt-driven machine, fitted with two-speed gear, weighing only 120 lbs. Another new machine is one of 2¾-h.p., with two-speed gear and chain drive, and fitted with magneto ignition, also chain-driven, while a 2¾-h.p. tricycle on similar lines is also shown. Special attention has been devoted to the details, the driving chains, for instance, being provided with light guards, which

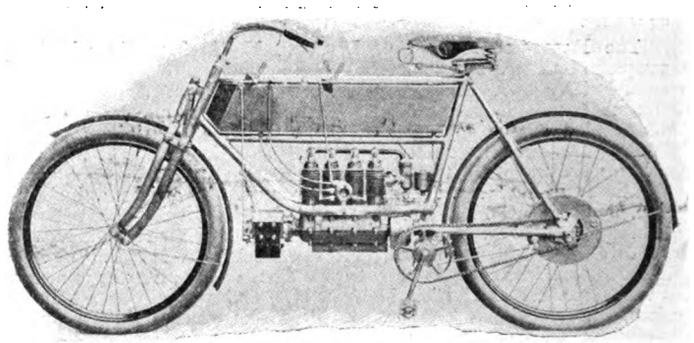

Fig. 11.—The F.N. Four-Cylinder Motor Bicycle.

protects them from mud and dirt. A working model of the Phœnix two-speed gear is also to be seen. This consists of a train of epicyclic gearing combined with a special form of clutch, actuated by a wire cable. Altogether, the 1905 models should fully uphold the high reputation the Phœnix machines enjoy in the motor-cycling world.

A tri-car with a detachable canopy and front storm screen forms the most novel exhibit on the stand of Phœnix Motors, Limited. The machine is known as a Trimo, and, so far as the general arrangement is concerned, the changes are to be found mainly in the details. No pedals are fitted, and this permits of wide footboards being provided, these being hinged to give access to the engine, a 3½-h.p. fan-cooled Phœnix, specially made by the Minerva Co., with mechanical valves and magneto ignition. The carburettor is the new Phœnix automatic—a very efficient and economical device. The drive is by Reno!d, ⅝ in. pitch, roller chain from a clutch on the engine to a countershaft, and thence by chain to the two-speed gear on the rear axle, the chains being well protected by covers. The silencer, which is of large dimensions, is provided with a cut-out operated by a small foot lever. Ample brake power is provided, pedals controlling two band brakes acting on the drums of the front wheels, and a fibre-covered circular solid steel rod working on a grooved drum on the rear wheel. The whole of the mechanism is protected from dust and dirt by a leather apron hung from the frame. The rear seat is of a large pan shape, such as is used on agricultural machines; it is mounted on flexible springs, while the front seat is also spring suspended, thus rendering the machine practically free from vibration.

The well-known Brown motor-bicycle is shown by Messrs. Brown Bros., Limited, in two sizes—3½-h.p. and 2¾-h.p.—both engines having mechanically-operated inlet valves. The machines are belt-driven, and we noticed that one is provided with the B.S.A. spring frame, to reduce vibration, and another with magneto ignition. Two sizes of the Bat motor-bicycles are to be seen at the stand of the Bat Motor Manufacturing Co., Limited—2¾-h.p. and 3½-h.p.—these being fitted with either rigid or spring frames. Arrangements have now been made whereby these machines can be fitted with high-tension magneto ignition, and, in the case of spring-frame machines, with pedals. A 3½-h.p. two-seated forecarriage is also displayed, this machine being interesting on account of the wind-scoops and fan provided to assist in the cooling of the engine.

A three-wheel two-seated car on novel lines, and known as the Wolf, is exhibited by the Wearwell Cycle and Motor Carriage Co. It is fitted with a 6-h.p. water-cooled Fafnir engine, placed longitudinally in the frame. The latter is built of steel tubing, well stayed, and is carried on the front wheels by two elliptical springs. Steering is controlled by an inclined wheel, and all the controlling levers are brought well within reach of the driver. The power is transmitted from the engine through a clutch to a gear-box which gives two speeds, the pinions of which are always in mesh. From the gear-box the power is transmitted by a longitudinal shaft and bevel gear to the rear road wheel. The water circulation is maintained by a pump driven off the half-speed shaft and a radiator. The body is coach-built, with aluminium panelling, while the bucket seat for the driver is provided with springs. The wheel base is 5 ft. 2 in., and the track 3 ft. 7 in.

A tri-car on exceedingly novel lines is shown by the Sharp Air Spring Co., Limited, Hammersmith. Not only is the frame of special construction, but each of the three road wheels is carried in forks provided with what is known as an "air spring," this consisting of a cylinder to which the upper part of the frame is connected, and a plunger attached to the lower portion. Air is pumped into the cylinder, so forming a cushion which takes up all vibration due to the engine

Digitized by Google

or bumpy roads. The motive power is supplied by a 4-h.p. V-shaped double-cylinder engine, transmitting its power to the rear road wheel. There are a number of other features in this machine which cannot be dealt with in the brief space at disposal in a show report, these including a differential fly-wheel, the special claim for which is that it absorbs the shocks of the explosions even at very slow speeds. The fly-wheel is made in two parts, with a hollow interior, having a series of radial springs and a set of gear wheels which act in such a way as to gear down the fluctuations of the impulses. The steering is also of what is known as the castor type. The machine, which has been built to the designs of Professor Sharp, is exceedingly light, weighing complete only 180 lbs.

Some excellent specimens of petrol motors both for use on motor-cars and launches are displayed in the Gallery by Messrs. DEAN AND BURDEN BROS., LIMITED, of Salisbury. They range from a 3-h.p. single cylinder to a 20-h.p. four-cylinder. Dealing with the latter, it has four separate cylinders 90 mm. bore by 115 stroke. The inlet valves are of the suction type, and are readily accessible. The cam shaft is entirely enclosed, the cams being solid with the shaft. The water circulating pump is driven direct by the engine; a governor is fitted, this being adapted to act on the admission. Large hand holes are provided in the aluminium crank case. The engines throughout appear to be of sound construction, a special quality of red anti-friction metal being used for the bearings. The 3-h.p. launch motor is provided with a speed reduction gear in the crank case, the propeller shaft being coupled, not to the engine shaft, but to a short one running at a third of the speed of the latter.

Quite a new design in motor-cycle engines is to be seen at the stand of Messrs. A. W. WALL, LIMITED, Guildford. It forms part of the new "Roc" machine, and its characteristic feature lies in the fact that there is no cam shaft in the usual sense of the term. The machine is driven by a chain from the engine to the countershaft, and thence by a belt to the rear road wheel. The countershaft runs at half the speed of the engine, and advantage is taken of this to fit to it the cams operating the inlet and exhaust valves, the stems of which, as will be seen from Fig. 13 are arranged at an angle. The valve and explosion chamber can, as a result, be readily opened out for inspection. The ignition is by the Eisemann high-tension magneto, which is also driven by the half-speed countershaft.

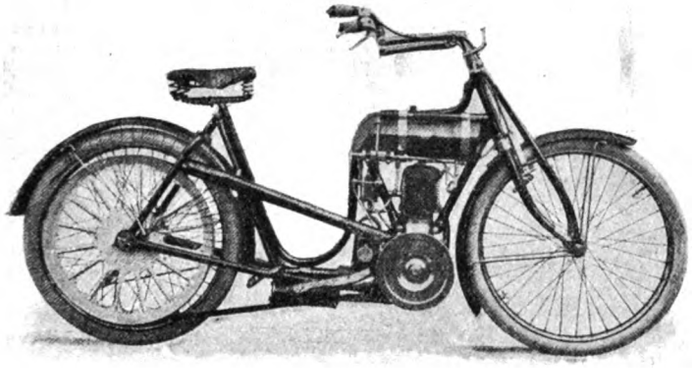

Fig. 12.—The "Roc" Lady's Motor Bicycle.

The engine, which is of 4-h.p., has a cylinder 85 mm. bore by 85 mm stroke and is provided with two large outside flywheels. The cylinder and top portion of the crank case, which is divided horizontally, are in one piece, whilst the lower half of the crank case forms an integral part of the frame. A special form of fibre clutch is fitted in connection with the rear wheel, so that the engine can be started before the rider mounts the machine. Altogether the "Roc" is to be counted amongst the most interesting motor-bicycles in the show. Fig. 12 depicts the lady's motor-bicycle, which is also to be seen at this stand. This is a 3-h.p. machine with belt drive and magneto ignition.

Quite a new departure in induction coil construction is to be seen at the stand of Messrs. COHEN BROS., West Kensington, W. These coils are so arranged that any one bobbin (or cylinder) can be removed without taking off the coil from the car or disturbing any connection. Each bobbin is enclosed in a separate ebonite case, thus ensuring complete freedom from damp, and so thoroughly insulating the same. Should the coil, or, in the case of a multi-cylinder coil, any one of the coils fail to work properly, it can be pulled out of position without loosening any of the connections, and if a spare coil is carried this can be substituted. The new coil is made for one, two, three, or four-cylinder engines, and is fitted with a single trembler. The latter is mounted on an ebonite base, and is so fixed to the coil that it can be easily detached and instantly replaced by a spare one should it get out of adjustment. The condensers are made separate from the coils, and are arranged together in the centre of the coil-box. Those who have suffered from induction coil troubles in connection with the ignition of their motors should make a point of inspecting Messrs. Cohen Bros.' new arrangement. The exhibit also includes a display of ignition accessories and a range of specially-strong accumulators.

A number of interesting novelties to motorists are shown by Messrs. FLEMING AND CO., of Paris, including the Simplicity and Eclair nail catchers for tyres, which were recently illustrated in the *Journal*, and "Pneu Cure." The latter is a new preparation for repairing cuts in outer covers of pneumatic tyres, and if the specimens of repaired tyres on view are any criterion, it should prove a useful adjunct to all tyre-repairing outfits.

A motor-bicycle stand or jack, known as the Vim, is shown by Messrs. THOMAS SLACK AND CO., LIMITED. This is put in action as a stand by pushing a lever forward, thus also raising the back wheel. Rapidity of movement is a feature of the appliance, which folds up automatically

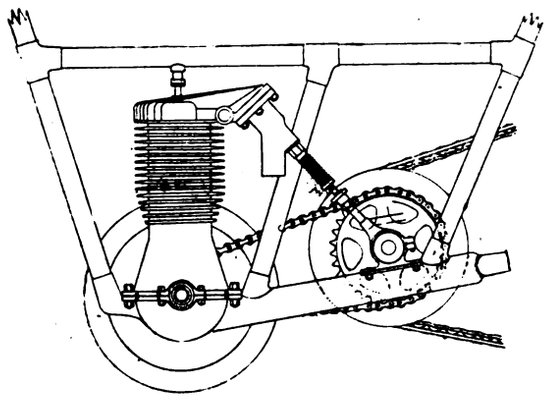

Fig. 13.—The new "Roc" Motor-Cycle Engine.

when collapsed, being held rigid by springs so that the machine can be started without dismounting.

The Grose non-skidding and puncture-proof bands are exhibited by Messrs. GROSE, LIMITED. The features of these well-known bands are the intermediate leather, which prevents the rivets from injuring the rubber cover, the leather cover vulcanised on the ordinary tyre, which is taken down over the beaded face, and a leather tread with steel studs, the whole going to form a band which prevents punctures and skidding, and does not interfere with the resilience of the tyre.

Mr. E. J. HARDY, of Coventry, has a representative display of motor parts and accessories, including the Guenet coils, the Lithanode accumulators, Stevens' engines, and other well-known specialities. Some of his own manufactures are also on view, including well-made steering gears. A good voltmeter on this stand is the Glorius, fitted with a two-way switch and interrupter, which can be operated at the same time.

On the stand of the SOUTH BRITISH TRADING CO., LIMITED, is the Vindex Special motor-cycle for 1905. The regular model has a 2¾-h.p. engine, a larger size being of 3½-h.p. The frame is built lower than formerly, and a novel feature is introduced which allows the rear wheel to be removed from frame without detaching the stand. The oil tank and pump are fitted in the front of frame, and all that is required to put oil into engine crank case is simply to raise and lower the pump plunger. On the same stand the Fisk motor tyres, which have been previously described in these columns, are also attracting considerable attention.

MINERVA MOTORS, LIMITED, are making three sizes of motor-bicycle for the 1905 season—2-h.p., 2¾-h.p., and 3½-h.p.—the engines being in each case equipped with mechanically-operated inlet valves and fitted in a vertical position. The belt system of transmission is still retained, while some of the machines are provided with Eisemann high tension magneto ignition. The method of driving the magneto is somewhat novel; it is illustrated in Fig. 14, from which it will be seen that the machine is

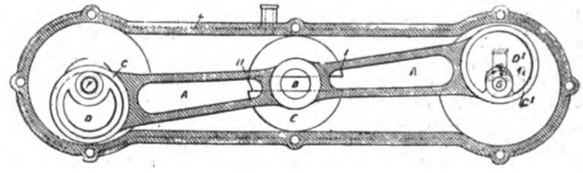

Fig. 14.—The "Minerva" Magneto Driving Gear.

supported by a bracket fitted to the front of the motor. Two eccentrics are employed, D and D 1. D is attached directly to the half-speed shaft of the motor, and D 1 to the spindle of the magneto. The two eccentrics are coupled together by means of eccentric straps A and A 1. The whole is enclosed in an aluminium case L, which ensures perfect lubrication. The case in the centre carries a guide E, for the rod connecting the two eccentrics, the guide oscillating slightly when the device is working, the two eccentrics revolving in opposite directions. A two-speed gear, already illustrated in the *Journal*, is fitted to some of the 2¾-h.p. machines, while another new departure is the provision of a spring front fork to reduce vibration.

Digitized by Google

As usual, Messrs. ALFRED DUNHILL, LIMITED, have a varied display of "everything but the motor." In clothing is a very representative range of well-designed garments, including coats and rugs specially intended to withstand the cold winds of the winter season. Ladies' garments are quite a special feature of the display, some of Mr. Lovegrove's

Fig. 15.—Dunhill's Front Glass Screen as fitted to a Panhard Car.

well-known designs having now been added to the selection. Hoods and veils are also included in that department. But the great novelty consists in the development in acetylene work which has been made possible by the firm's acquisition of the sole rights to make dissolved acetylene in a suitable form for lighting automobiles. A container is provided giving a supply of gas sufficient for a headlight for forty hours, either continuously or intermittently. This, fully charged, weighs only 23 lb., and all that has to be done to secure a light is to turn the tap and light the gas. By placing the tap immediately in front of the driver the light may be lowered to any degree as desired. By allowing the gas to be turned down when the full light is not required a great saving is secured and the new development will be regarded with interest by motorists. We illustrate Messrs. Dunhill's glass shield for use in all weathers. As will be seen, the upper portion is hinged, and when not wanted in that position may be folded down, the lower portion still affording an efficient screen and apron guard. The method of fixing is well designed to secure rigidity; at the same time it can be easily removed or attached. The "Kennard" valise, the Elliott motormeter, petrol gauges, sparking plugs, and accessories of every kind complete a very representative display of general interest.

PEARSON'S special 5-volt accumulators are to be seen in the Arcade, these securing a powerful spark and exact ignition. A great advantage is that these accumulators may be carried as spare cells, and when required, the electrolyte, supplied in bottles, is poured in and a full voltage and capacity obtained at once.

Castings for small petrol motors form a prominent feature of the display of the MOTOR CASTINGS CO., LIMITED, which also exhibits a Blake 6-h.p. twin-cylinder engine for a motor-launch, and a 4-h.p. engine arranged to work with paraffin, complete with propeller and reversing gear. An ingenious yet simple free engine pulley for use on motor-cycles is to be seen at the stand of Messrs. OSBORNE BROS., Lincoln. No springs are employed in the device, the grip being obtained by steel balls; it enables the engine to be started by hand and to be disconnected at will from the driving gear when riding in traffic. It is also being supplied combined with a two-speed gear.

A steering wheel made in aluminium is one of the automobile attractions on the stand of Mr. R. W. COAN, whose specialities in that metal are familiar enough to all engaged in motor-car work. The idea of the new steering wheel, the rim of which is hollow, is to allow the hands to be warmed while operating the wheel. By means of a flexible tube the water from the engine head is circulated through a hollow spoke and thence round the wheel, it being claimed that no more than half a minute is occupied in securing sufficient heat for the purpose.

The OTTO-BENNETT MOTOR CO. show the well-known "Otto" band, a detachable, non-skidding leather band which has already won distinction in the motoring world. Unlike many such devices, the Otto band does not present an unsightly appearance, while the security of the attachment fastens it to the tyre as tenaciously as if it were solid with it. With it in use the fear of skidding is absent, while the risk of punctures is overcome. The chrome leather of which it consists is cut out at the inner and outer faces of the band, which is surmounted by a narrow tread, on which are fixed tempered steel rivets. By means of a flexible wire it is easily detached or attached to the tyre, thus providing a means to economy which is being regarded with increasing favour by motorists. The "Sée" unpuncturable bands are also on the stand, and their neat, strong, and durable qualities will be appreciated by those who do not object to a permanently fixed band. This band is made of toughened leather fitted with a strip on the tread carrying steel studs in interspersed rows. The Stepney detachable wheel and the Avon tri-mobile, a three-wheeled motor-vehicle of great efficiency, the features of which have already been described in the *Journal*, are other specialities of the Otto-Bennett Motor Co., which has also taken up the agency for the Force carburettor illustrated and described in our issue of May 23rd, 1903. This is designed to give a correctly-proportioned mixture, and obviates the presence of the levers and connections usually necessary.

The display of lamps is fairly comprehensive. The 20TH CENTURY MANUFACTURING CO. have a good show of headlights, sidelights, and tail-lights, and take advantage of the occasion to circulate a catalogue of considerable practical value to all motorists, the directions for use and the drawings of the various parts of lamps being useful information for the amateur.

A very interesting display of the Fafnir petrol engine for motor-cycles and cars made by the Aix-la-Chapelle Steel Works is to be seen at the stand of Messrs. STRAUS and COMPANY, London, E.C., the British agents. The motors range from 3-h.p. to 24-h.p. The air-cooled motor-cycle engine is a new model with mechanically-operated inlet valve arranged in the cylinder head, with adjustable tappet rods. The speed of the engine is regulated by varying the lift of the inlet valve, this being accomplished by means of a wedge piece which may be inserted between the cam and the side rod operating the valve. A device for lifting the exhaust valve is also provided to facilitate starting. The engine is of 3-h.p., having a cylinder 75 mm diameter by 88 mm. stroke; it is supplied either for accumulator and coil or magneto ignition; in the latter the magneto is driven by an enclosed train of three spur wheels mounted on the side of the crank case. Fig 16 illustrates the Fafnir 6-h.p. double-cylinder

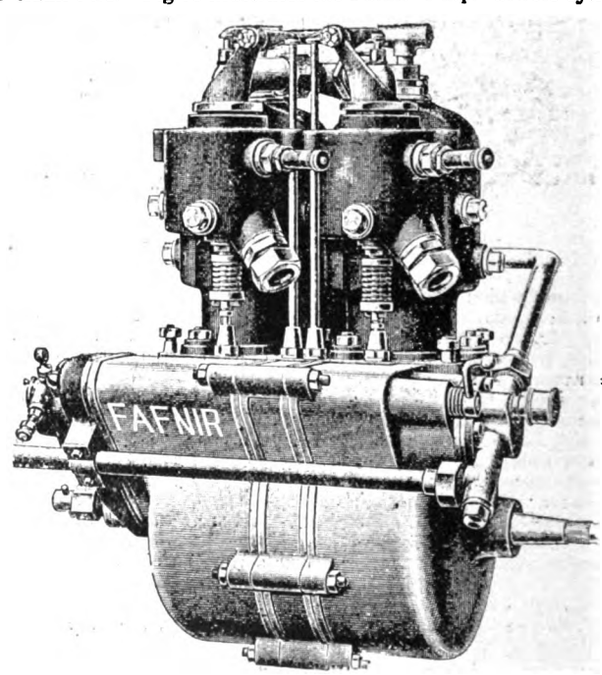

Fig. 16.—The Fafnir 6-h.p. Double-cylinder Engine.

engine for light cars; this is, as regards the inlet valves and cylinder dimensions, on similar lines to the motor just described, an interesting feature being that the pump is combined with the engine. It is driven off the crank shaft and is seen at the right of the illustration. Other engines on view comprise examples of the 10-h.p., 16-h.p. and 24-h.p. four-cylinder type, while reference should be made to the Fafnir change-speed gears, differential shafts and other motor components.

(To be concluded.)

CORRESPONDENCE.

ELECTRICAL v. WATCH TIMING.

To the Editor of *The Motor-Car Journal.*

Sir,—Considering the free use Mr. Crawley made of my name on a recent Thursday at the A.C.G.B.I., I am surprised that he did not take the trouble to advise me of the meeting—it would have been an act of courtesy had he invited all the timekeepers. I received a most courteous note from Colonel Holden at noon on the same day, unfortunately too late for me to arrange to get up from Birmingham. In the first place, may I ask what became of the paper, as only an ill-advised argument against the present system of timekeeping appears. Mr. Crawley says that supposing "a watch registers 2 1-5th sec., this merely means that the button was pressed somewhere between 2 1-10th and 2 3-10th sec."; such a case is impossible with the split seconds chronographs used by Mr. F. Straight and myself. If our watches register 2 1-5 sec. that time has elapsed.

In mentioning the equal running of the watches he argues from the same standpoint, which is erroneous. It is unfair to assume that one watch gained on the other when they both registered the same fifth exactly. These watches have now been used on nineteen occasions in club events, totalling 163¾ hours, and every time when stopped at the close of the day's events they have registered the same fifth exactly—there is no *if* about it.

Mons. Tampier, the French timekeeper, is credited with knowing something about timekeeping, and I take it as a great compliment that he was so convinced of the accurate running of my three chronographs in the Irish Gordon Bennett race that he purchased the only other similar chronograph on sale last year, and he actually started and timed this year's Gordon Bennett race with it.

Watches have been made and tested to time to 1-300th sec., but the speed at which they have to run soon wears them out, and 1-5 sec. has been found to be the smallest interval to which a watch can be cut to give accurate results for any length of time.

If some method of timing finer than 1-5 sec. is required, let it be got by all means, but there is no need to try and discredit instruments which are at the moment the best and most reliable in existence, and, whether the distance be one mile or 1,000, will record the time accurately to 1-5 sec. It should not be forgotten that the owners may be required to time events for which the electric apparatus is altogether unsuitable.

May I mention, in proof that I have no axe to grind, that I am not interested in the manufacture or sale of watches, and have never accepted from the club a fee or cent towards my out-of-pocket expenses?

In conclusion, I should like to make a suggestion *re* the electric timing apparatus, viz., that Kew-tested clockwork be used to bring it into line with the Kew-tested chronographs employed by the club timekeepers.—Yours truly,

T. H. Woollen.

A SCOTTISH RELIABILITY TRIAL.

To the Editor of *The Motor-Car Journal.*

Sir,—My committee have been considering the desirability of announcing a Glasgow to London Reliability Trial similar to those so successfully conducted by them in each of the last three years.

While they are assured that this would again meet with a gratifying amount of support, there is a general feeling that such a trial is not now sufficiently severe or conclusive, and that the interests of the automobile trade would be better served, and an even greater public interest excited, were the test more exacting and comprehensive.

They have accordingly resolved, should their proposal meet with encouragement from manufacturers and agents, to organise a reliability trial occupying say three days, in Scotland, embracing in its itinerary the principal cities and towns and some of the most mountainous roads and passes in the Scottish Highlands, and including not less than three hill-climbing tests of lengths and severity unequalled in any reliability trial or hill tests yet held anywhere.

My committee are of opinion that a trial of this nature would command wide-spread public notice and would test the capabilities of touring cars to an extent not yet attempted.

My committee would esteem it a favour to have the opinions of any of your readers interested in the matter, and to know whether, subject to their approval of the conditions of entry later, they would be prepared to make any entries.—Yours truly,

Robert J. Smith,
Hon. Sec. Scottish Club (Western Section).

BRITISH v. FOREIGN CARS.

To the Editor of *The Motor-Car Journal.*

Sir,—I consider the English firms can account for the increased importation of foreign cars by the greatly increased popularity of the motor, which has come along so rapidly as to open a market in England that could not possibly be filled by the home factories; but I do not think any reflection can be saddled on the British manufacturers, who, judging from the recent correspondence, seem to have made phenomenal progress. Mr. Jarrott points out the immense growth of French firms, with which he is more intimately acquainted, and, with a true Englishman's feelings, wishes to encourage English firms to follow, offering his support when he can obtain his requirements in England, and in reply I ask him to wait a very little while, probably next year, and he will realise his desire.

Under the English manufacturers' surface of nonchalance there is activity little dreamt of. Going back two years, I am pleased to say our 1901 business was doubled in 1902; 1903 trebled 1902; and although we have gone away this year from the usual slavish imitation of the foreigner, by adopting a principle of worm gear unheard of in connection with motor-cars on the continent, yet I have every confidence that when my company's balance-sheet appears for 1904 it will be quite as satisfactory as hitherto.

This general increase must account for an enormous reduction in foreign importation, and I believe if Mr. Jarrott renews the subject at the end of 1905, he will be pleased with the position of the English makers, realise them as powerful competitors, and decide to sell well-finished English cars in preference to foreign.—Yours truly,

Raymond Dennis.

THE LANCHESTER CAR.

To the Editor of *The Motor-Car Journal.*

Sir,—I shall be glad if any readers of the *Journal* can give me information about the "Lanchester" car. I have read their descriptive book and watched cars running, but should like to know from a disinterested owner, preferably one who has also owned or driven the usual type of car; with wheel steering, water cooling, high tension ignition, etc., the following:—

1. Is tiller steering as fitted by Lanchester preferable to the wheel? 2. Is air cooling on these cars a success? 3. Is range of speed variation on any particular gear as great with the Lanchester fixed ignition as with the usual variable point of ignition? 4. Do the governor levers give as great a range of control as the throttle lever on ordinary cars and can one or both cylinders be cut quite out? also what happens if one lever is set to cut out the governor oftener than the other lever? 5. Are control levers and speed levers between the front seats as convenient both for daylight and night driving as when arranged on column of a wheel and at off side of car? 6. Is Lanchester *less* or *more* trouble to keep in good running order, adjust, &c.? 7. Is the arrangement of change speed, clutch, &c., hand operated as Lanchester as safe in emergency as the usual clutch and brake pedal and lever at side of car? 8. How does the Lanchester compare for hill climbing, speed and comfort with ordinary type same power?

Mr. Luff-Smith on a 96-h.p. Wolseley, fitted with Touring Body.
Photo by [*Mr. A. E. Newton.*

If any one will give above and any other information he can *re* these cars, he will, I am sure, receive not only my own but also the thanks of many other would-be motorists who are interested, but cannot, like myself, get disinterested advice.—Yours truly,

Enquirer.

MOTOR BOATING.

To the Editor of *The Motor-Car Journal.*

Sir,—Your description of the run of the Mercedes IV. from Dover to Putney, while it forms yet one more achievement for the motor-boat and demonstrates its great possibilities under varying conditions, is, I think, rather inclined to lay too much stress upon the dangers and perils attending such a cruise.

I think that one may fairly consider that recent events have removed the small motor-driven craft from the experimental and hazardous stage, and that the public need no longer look upon these attempts as attended with perils, except under the most unfavourable

Digitized by Google

conditions. In support of this may be cited the recent performances of the Napier Minor, a boat which my syndicate had the pleasure of constructing under my supervision.

Although the boat has made several trips from Dover and Brightlingsea to Southampton without stopping, taking the weather as it came, I have never heard Mr. Evans, her helmsman, on these occasions, or anyone on board, say anything that would lead one to believe that a trip, say from Brightlingsea to Southampton, was anything more than an ordinary pegaway run. I have heard of the boat leaving Dover Harbour at a time when the cross-channel boats were having a very bad time of it. The foregoing goes to demonstrate that a properly designed and constructed motor-boat, fitted with a good engine, forms one of the safest and most comfortable craft one can have.—Yours truly,

S. E. SAUNDERS.

FOLDING BICYCLE WANTED.

To the Editor of *The Motor-Car Journal*.

SIR,—I have been considering that it would be a very handy thing to be able to carry a bicycle on my motor-car. Now I remember reading some time ago of folding bicycles which were recommended for military use. The ordinary bicycle is, of course, too long and awkward to put on a car.

One point of value in the ability to conveniently carry a bike would be, when one came across rough roads or newly metalled ones, one might finish the journey on selected parts of the road or on the footpath. Can any of your readers give me names and addresses of makers of such bikes?

J. TEARE.

A NOISY ENGINE.

To the Editor of *The Motor-Car Journal*.

SIR,—The following notes may possibly be a reply to "H. W. P.'s" letter in the *Journal* of the 12th inst., being cases of noise in cars that came under the writer's notice:—1. Due to slightly worn, too soft gear, that ran fairly quiet when engine was driving, but made a fearful noise when second shaft wheel was driving first down hill with clutch out. 2. In an old car which had little brake pads to slow down clutch cone when withdrawn—these caused noise from mal-adjustment. 3. Too much end-play in first motion shaft; when clutch was withdrawn shaft was pressed endways, and, as there was little clearance between gears, one of them fouled a projection in gear-case.—Yours truly,

R. W. BUTTEMER.

ENGINE TROUBLES.

To the Editor of *The Motor-Car Journal*.

SIR,—A friend of mine had considerable trouble lately with a 12-16-h.p. four-cylinder Peugeot. Only two cylinders would work anything like well, and as soon as the throttle was fully opened, the engine would set up a noise just as if there were water in the cylinders. These were, however, tested hydraulically and found all right. The engine was taken down and examined thoroughly; timing, ignition, compression, etc., were all right. We were at our wits' end, when it was suggested to examine the exhaust pipes and silencer. These were simply choked through over-lubrication, and thus the cause of all the trouble. I had often warned my friend, but, as he never had had any trouble from the magneto ignition, he did not care. Perhaps you will kindly publish this letter, as it might assist fellow motorists.—Yours truly,

P. ROELOFS.

OVERHEATING TROUBLES.

To the Editor of *The Motor-Car Journal*.

SIR,—Referring to the letter of Mr. A. E. Coleman on the above in the *Journal* of the 12th inst., I have had some eighteen months' experience of a 10-h.p. single-cylinder Rex car, and may possibly be able to help. I should not advise him to alter the water pipes (½ in. bore), as I have found these quite large enough for the purpose. He will probably find that the trouble is due to the guide being a little too tight for the stem of the exhaust valve; this would have the effect of holding the valve up a little during the explosion and so allowing the exhaust gases to burn the stem of the valve. The remedy for this is obvious.

The pump may possibly need attention, as the cog-wheel type of pump requires careful adjustment to get the best results. I should also advise the fixing of a small screw-down grease lubricator in some convenient position on the pump; this makes a surprising improvement in the running of the pump.—Yours truly,

ARTHUR S. M. BEST.

To the Editor of *The Motor-Car Journal*.

SIR,—One of your correspondents, Mr. A. E. Coleman, inquires for information regarding his Rex car. As an owner a 10-h.p car of the same make, my experience may be useful to him. My only trouble from overheating has been through the water-pipes, and occasionally by the radiators becoming blocked up. I strongly advise your correspondent not to alter the contact-breaker or pump, but to thoroughly clean out his circulation pipes.—Yours truly,

P. TURPEY.

COST OF RUNNING.

To the Editor of *The Motor-Car Journal*.

SIR,—As you have expressed a wish that motorists would state the cost of driving their cars, I venture to send you details relating to my 10-12½-h.p. car. The expenses cover the period from 17th November, 1903, to 21st November, 1904, and the car has been driven 2,870 miles:—

	£	s.	d.
Insurance	10	0	0
Registration and licences	2	5	0
Clothing	0	16	0
Rent	13	15	0
Repairs and overhauling	23	15	1
Accessories	5	16	11
Oil, petrol, and carriage of same	11	0	5
Man cleaning car	3	1	0
Batteries and charging	2	10	10
Tyres, solution, tubes, repairing bursts	15	4	6
Sundries	2	4	6

I should like the opinion of your readers as to whether £10 for insurance is worth it. I pay £15 per annum for rent and 2s. 6d. per week to a man for cleaning the car. Repairs include cost of new piston rod, due to stupidity of local repairers, who screwed the old rod so tightly that it seized.

Accessories include a Salsbury tail lamp, to take the place of one which was "thrown in" with the car when I purchased it, and which was therefore useless. The battery also turned out a failure and another one had to be purchased.

My rear wheels are protected by Samson non-skidding bands, but, notwithstanding, I had a burst a short time ago. I think, however, they save the tyres a good deal and are worth the extra expense. I also had a burst in August last caused by a canvas patch which was badly solutioned on inside the cover. A wrinkle in it gradually chafed the tube until it burst and destroyed the cover. The local repairer again!

Without allowing anything for depreciation I think you will find this works out at over 7½d. a mile.—Yours truly,

S. C. G.

MOTOR-CAR REPAIRS.

To the Editor of *The Motor-Car Journal*.

SIR,—Motor-car repairing establishments are opening up in every city of the land, but competent automobile repairers are still scarce. Various tradesmen whose experience is entirely foreign to motor engineering have recently blossomed out into full-fledged motor-car experts, and are leaving unmistakable marks of their incompetence upon the vehicles entrusted to their care. It is not uncommon for an automobile which merely required some slight adjustment or replacement of parts to receive at the hands of these men a thorough "overhauling," with the result that serious and complete derangement follows, and the owner is put to much trouble and expense to have his car set to rights again. No man is competent to make a specialty of repairing motor-cars unless he is familiar with their construction as well as their operation. I would advise my fellow motorists to endeavour to select some mechanic of reputation in their town who will become interested in their car and be able to make such repairs to it as may be needed. If there is a newly-opened repair shop in the vicinity, an automobilist would be well advised to assure himself of the competence of the repairer before he entrusts his car to him. The little adjustments he should learn to make for himself, and, above all, he should remember that "an ounce of prevention is worth a pound of cure."—Yours truly,

L. P. DARBY.

A USEFUL HINT.

To the Editor of *The Motor-Car Journal*.

SIR,—The following little incident may be of interest to some of the readers of the *Journal*. Whilst out on my car the other day I had the bad luck to get a puncture. I removed the tyre, and was about to mend it, when I found I had no solution in the repair outfit. Being about five miles from the nearest village, I was in despair until I suddenly remembered that petrol was a rubber solvent. Finding a piece of electrical binding rubber, I put it in a tin box, poured some petrol on it, which readily dissolved it. This making some very fair solution, I mended the tyre, which is still holding up well.—Yours truly,

J. C. FAIRCLOUGH.

THE HITCHON-WELLER GEAR.—Xenophon writes:—Would any reader of the *Journal* who has tried the Hitchon-Weller gear give his experiences and opinion of the same?

PANHARD IGNITION.—R. H. H. writes that he would be glad of any hints with regard to the adjustment of the ignition of the latest type Panhard cars from users of these vehicles.

[Owing to the pressure on our space this week a number of interesting letters have had to be held over.—ED. *M.-C. J.*]

CLUBS AND ASSOCIATIONS.

THE LADIES' CLUB.

AT the last meeting of the committee of the Ladies' Automobile Club of Great Britain and Ireland the following ladies were elected to membership :—Lady Greenall, the Lady Margaret Compton, Mrs. Almeric Paget, and the Viscountess Southwell.

The committee have arranged with Mr. R. Sedgwick Currie (consulting engineer to the L.A.C.), to give a course of lessons, to members of the club, on the internal combustion engine as applied to self-propelled vehicles. The first of these will be given at the club on Tuesday, the 22nd November, at 3 p.m. In all, there will be six lectures, the following being a general outline of same :—Lesson I. : Principle of internal combustion engine. Different types of engines (1, 2, 3, and 4 cylinders). General outline of all working parts. Lesson II. : Full description of all working parts and their uses. Lesson III. : Working of engine and governing gears, carburettors. Lesson IV. : Gears, brakes, transmission (belt, chain, live axle), differentials. Lesson V. : Clutches, water circulation, pumps (oil and water), silencers. Lesson VI. : Ignition (tube, coil, and magneto), commutators, tremblers.

Lieutenant Windham, R.N., will deliver a lecture on some of his motoring experiences, to members of the club and their friends, on Wednesday, December 7th, at 3.30 p.m.

SHEFFIELD.

UNDER the auspices of the Sheffield Automobile Club, Mr. S. F. Edge has been lecturing on motor-car racing in the cutlery centre. Alderman W. E. Clegg was in the chair, and among those who were present were Mr. Harvey Foster, Dr. Thorne, Messrs. A. S. Fawcett, J. W. Fawcett, J. H. Pickford, James Barber, F. Mellowes, C. A. Clarke, J. R. Wade, and others. In concluding his address, Mr. Edge spoke of the great influx of trade which followed the victory in the Gordon Bennett contest. At one time it was impossible to get springs in England which would stand the tremendously rapid movement, but they could now obtain them in Sheffield second to none in quality. They had only to prove to the world that the best springs were made in Sheffield, and it would mean hundreds of thousands of pounds for springs alone to that city. The same thing applied to tyres, and wood for the wheels, both of which they could now get in England as well as on the Continent. The amount of capital locked up in horses was enormous, and mechanical traction must therefore be adopted gradually. He then presented the cups given to the Sheffield Automobile Club by Mr. Harvey Foster to the winners in the hill-climbing competitions held at Padley Wood some time ago. The cup for cars was won by Mr. Frank Churchill, with his 14-h.p. Hallamshire, whilst the motor-cycle competition fell to Mr. F. Oates, with his 2¾-h.p. De Dion tricycle. Subsequent to this a series of bioscope pictures were thrown on the screen, illustrating the Gordon Bennett race in Germany last summer, motor-boat racing, motoring in the clouds, and other interesting scenes. At the close a vote of thanks to Mr. Edge was heartily carried on the motion of Ald. Clegg, seconded by Mr. J. H. Pickford, and a similar courtesy was extended to the chairman on the motion of Mr. F. B. Cawood, seconded by Mr. A. S. Fawcett. About 600 members and friends of the Sheffield Club were present.

HULL.

THE Hull Club is developing the social side, and automobilists have enjoyed a social event at the Imperial Hotel, Hull. An incident of the proceedings was the presentation of badges to the winners of the non-stop run to York on September 29th. These awards were decorated with the City arms in enamel, with a sparking plug and a steering wheel worked into the design. The winners were Mr. J. H. Nicholson, on a 2¾-h.p. Humber; Mr. J. F. Freeman, 3½-h.p. Rex; Mr. A. E. Hagestadt, 2¾-h.p. Riley; Mr. G. H. Parker, 2¾-h.p. De Dion; and T. C. Philipson, 2-h.p. Minerva. Mr. G. H. Strong presented the badges.

Colonel Broadly, Mr. W. Glossop, and Dr. Coates, members of the club, wrote regretting their absence. Mr. G. M. Heald is the secretary of the club, success to which was proposed by Mr. W. C. Dawson. The next meeting of the club will take place on the 1st prox.

A BINDING AGREEMENT.

AT the Brompton County Court, on Friday last week, before Mr. Stuart Sankey, Messrs. William Cole and Sons, motor-car builders, etc., High-street, Kensington, W., sought to recover £29 1s. from the Motor Car Emporium, Limited, Addison-road, W., the claim being in respect of work done and goods supplied.

Plaintiffs' counsel stated that in March last Mr. Frentzel gave an order for the plaintiffs to paint and varnish and upholster certain motor-cars. The price was agreed at the time, and as to this there was now no dispute. The work was properly done, but when application was made for payment the defendants commenced to raise objections as to the quality of the work. Evidence for plaintiffs and defendants having been given, his Honour considered that the defendants must be bound by the agreement. One or two small items, amounting to £1 18s. 6d., were struck out of the account, and judgment was given for the plaintiffs for the balance—£27 2s. 6d., with costs.

MILITARY MOTORS IN THE MANŒUVRES.*

MY paper necessarily centres round the work of the Motor Volunteer Corps, and very complete elaborate training had taken place previous to the manœuvres with the object of keeping the members of the corps tuned up to their duties. During the whole of this year tuning up has been taking place, and there has scarcely been a day during the year when no member of the corps had been requisitioned for duty. The announcement of the manœuvres was made in the month of June, and one might almost say that as far as the Motor Volunteer Corps was concerned their work in connection with these manœuvres began on the instant, for the various staff officers and others immediately began to requisition cars to carry them round about the proposed military area, which was to be in Essex. The actual manœuvres took place on September 14th, and, as far as the Motor Volunteer Corps are concerned, there were in all thirty-one cars and twenty-five cyclists, the various makes of cars which took part being as follows :—20-h.p. Peugeot, 18-h.p. Mercedes (two), 45-h.p. Mercedes, 28-h.p. Daimler, 14-h.p. Daimler, 24-h.p. Darracq, 30-h.p. Wolseley, 18-h.p. Wolseley, 10-h.p. Wolseley, 15-h.p. Darracq, 15-h.p. Panhard, 16-h.p. Napier, 18-h.p. Wilson Pilcher, 7-h.p. Star, 12-h.p. Richard, 12-h.p. Minerva, 10-h.p. De Dion, 9-h.p. De Dion, 10-h.p. White steam car, 12-h.p. New Orleans (two), 12-h.p. Wilson Pilcher, 20-h.p. Clement, 10-h.p. Clement, 10-h.p. Rolls-Royce, 10-h.p. Humber, 10-h.p. Thornycroft, 10-h.p. Argyll, 8-h.p. Brush, and 12-h.p. Mors.

This year a new departure took place, inasmuch as it was decided that the corps should go under canvas. For this purpose the old parade ground in the Meanee Barracks, Colchester, was secured. Every accommodation was found in the camp for ninety people, including motor

The Headquarters of the South Wales and Monmouthshire Club.

(*See page 771, last issue.*)

men and servants. On the night preceding the manœuvres the camp was a scene of very great animation as the cars and motor-cycles began to arrive. All that was known in camp at that time of the manœuvres was that General French and the invading forces had left Southampton some days previously, and were about to attempt a landing somewhere on the east coast. Consequently a great buzz of excitement rose throughout the camp at a late hour on that night, when nearly the whole of the cars and cycles were ordered to be somewhere in the vicinity of Clacton-on-Sea at 6 o'clock the following morning.

At Clacton-on Sea, where I was quartered, to try to take charge of General Sir Neville Lyttleton, the Director of the Manœuvres, I paraded for duty some three days before the 14th to await the arrival of Sir Neville. The actual landing place of General French's force had been kept a profound secret from the public. I was instructed to telephone to my head-quarters at Colchester to have a certain number of cars at Clacton-on-Sea at six o'clock in the morning, when it was expected that General French would land. The actual extent of the landing area was some seven miles, and the motor-cars were of extreme use in allowing the Staff officers to drive from one part to the other in order to study and supervise the various landing operations.

The morning arrived, so also did the cars from Colchester at six o'clock, after a very cold journey, having been ordered to parade at the camp at Colchester at about four o'clock. As a matter of fact, it was quite nine o'clock before the first transports with their accompanying cruiser came into view. About this time a smart car arrived driven by

* From a paper read by Mr. J. F. Ochs at the A.C.G.B.I. Thursday, November 17th, 1904.

Digitized by Google

Mr. Oliver Stanton, who had been deputed to drive General French, the Commander-in-Chief of the Invading Forces, throughout the manœuvres. He had accompanied the General as far as Southampton from Aldershot, and, instead of the car being taken on board the flagship, he had brought it round over land to Clacton, there to await his disembarkation. There was a general exodus of cars about mid-day back to Colchester.

Instructions were posted up every night in the ante-chamber detailing members to their various duties on the following day, and it was observed that for the next day's work the cars, instead of being sent to the coast, were to parade at various points either at Colchester or further inland. Few members seemed aware of the fact that during the night they had been massacred, since at 5 o'clock that morning Colchester had fallen into the hands of the enemy, nor did the painful operation seem to have spoiled their appetites for breakfast. I myself had remained at Clacton till ten o'clock the previous evening, and there was also a car waiting there driven by a much-esteemed member of this club, even more distinguished in the Irish Club, Captain Davies Goff. His car had the honour of carrying throughout the manœuvres H.R.H. the Duke of Connaught, the umpire in chief, and his staff.

After describing some of the detail duties of the Motor Volunteer Corps Mr. Ochs continued :—Breakdowns were few and far between ; but, to give an example of the organisation of the corps, I may tell you that I myself had a burst tyre close to a camp I had been taking my officers to. I managed to struggle on to the camp, and whilst a Pow Wow was taking place there, to my great satisfaction I saw in the distance Lord Russell, who had come on instructions received to relieve me, and to carry off my officers in triumph. I had, meanwhile, used the military telephone for communication with our camp at Colchester, to send me a new cover. Hardly had Lord Russell left with my freight than a car came dashing into the camp with the required spare cover.

About two weeks ago I was attending a discussion here as to inconsiderate driving, more especially in regard to fast cars on the road, and I was much struck by what appeared to be the opinion of members, that it was the fast cars that caused all the prejudice in this country. Now, during the manœuvres, although there were some forty or fifty cars generally rushing about in the manœuvre area, some at great speed, apparently no inconvenience was caused to the cavalry horses, nor to the great many people who were out every day. But it was a very curious fact that there was a little car belonging to an enterprising newspaper which was a fussy, noisy little car, and it caused the greatest inconvenience, and frightened, to my knowledge, several horses. I only illustrate this to show that the real inconvenience caused to other people is not necessarily caused because the car is a fast one.

As to the cars outside the corps, I am much indebted to Major Lloyd, the Secretary of the Mechanical Transport Department of H.M. War Office. He tells me that the heavy lorries were of extreme use in the manœuvres in bringing up supplies—in fact, in every way in which the lorries could be usefully employed. I am informed that at the present moment four heavy oil cars are on order for the Government and being built in this country. There is no doubt that if we do not yet compare favourably in the manufacture of touring and racing cars with our foreign neighbours, as far as heavy mechanical transport goes we are well ahead, but that must not be a reason for manufacturers of this country to mark time ; on the contrary, they will have to do all they can to compete with foreign made heavy transports. I believe I am not betraying a confidence when I tell you that in this respect some heavy lorries of foreign make were recently matched against two heavy lorries of recognised English make, and that the former in this particular case proved far more successful. Besides the heavy cars there were a great many of the dapper karki-coloured military cars seen running all over the place. It was a general experience of the members of the corps that, if anything, the officers assumed a rather too over-cautious attitude as to whether a car would go over a road or not. I personally think that a little excursion into a stubble field is not at all uninteresting. The old bugbear annoyance of being burdened with taking officers' luggage no longer exists ; express instructions have been issued to military officers that the cars are the private property of the drivers and must not be used without their consent for taking luggage.

All the members looked exceedingly smart and were careful of their uniforms, though one especially neat-looking gentleman spoilt the effect by wearing his leggings the wrong way round. I have said very little here about motor-cyclists, because I do not think there is anything that I can say about them that is new except that this year there were twelve used as combatants on either side. There is no official report so far, so one must conclude that the motor-car has become during the past year more and more an essential part of our military establishment. The same applies to France and Germany. When I was in Homburg this year I was eagerly questioned as to the position and status of the Motor Volunteer Corps ; since then I hear that a corps has actually been started. As to the future, it is either very easy or very difficult to prognosticate ; as far as I can see there is nothing to prevent the motor being used for the transporting of staff officers to the fighting line, provided there are roads. In this respect I was discussing with a staff officer the question of motors being used in actual warfare for staff officers—it being generally supposed that motors would only be good for manœuvres and staff rides—and he replied that surely transportation of officers from one quarter of the battlefield to another was employing cars in actual warfare. It is manifest that for ambulance work and telegraph service it is a model vehicle. Regarding the actual annoyance caused to troops on the march by motor-cars, of which we heard a great deal last year, I ventured at the time to rather believe that these reports were somewhat exaggerated. I think it will be gratifying to the corps in general, and to myself in particular, and I am sure to the members of this club, if I read you the following extract from a letter I have received from Sir Frederick Stopford and Colonel May on the subject :—"As it will be remembered, last year Lord Roberts honoured the corps by inspecting it at Marlborough after the work was finished, and this year the corps was if possible still more greatly honoured by being inspected at the conclusion of the manœuvres by H.R.H. the Duke of Connaught, and after the inspection, in complimenting Colonel Mayhew, he expressed his great satisfaction with the work that had been carried out by the cars."

A RUNNING-DOWN CASE.

At Liskeard County Court, Francis Bennett, of Pill, St. Stephen's-by-Saltash, claimed £50 of the Great Western Railway Company for injuries sustained through the negligent driving of a motor-omnibus by defendants' servants. Among the witnesses was Fredk. Tilford, the driver of the car, who said prior to June he had driven a motor mail-van in Liverpool for two years. The car in question could not travel more than twelve miles an hour, and he was driving about six miles an hour when the accident happened. The moment he saw plaintiff on horseback he blew his horn. He saw no signal made by plaintiff; if he had he should have instantly stopped. He allowed plaintiff sufficient room for a wagon to pass. The horse was walking quietly near the hedge on the other side as the car approached and was passing, when suddenly he felt the car bump. He at once stopped, and went back. J. Wright, leading motor-car driver for the Great Western Railway Company's service between Saltash and Callington, said the hedges on each side of the road were 17 feet 6 inches apart. The prints in the road made by the tyres of this car at the time were 9 feet from the hedge against which the accident had happened. The tracks of another car equipped with a different sort of tyre showed that in that case the car had kept to the middle of the road. B. Hawley, in charge of the G.W.R.Co.'s motor-car traffic in Devon and Cornwall, gave evidence as to the various speeds of the motor-car in question.

The jury found for plaintiff: £20 for injury to the horse, £3 for keep and attendance of the animal, £2 5s. for veterinary's fee, £1 for loss of use of the horse, and £1 for loss of time ; total £27 5s.

POLICE TRAP.

The Fairmile at Cobham has been again the scene of trapping motorists.

There is in active operation a police trap in the New Cross Road, London, S.E. It is mostly in respect to rear lights, and the police hold up all cars whose lights do not comply with the strict letter of the law. It is in operation mostly on Sunday evenings, and is located from New Cross Gate to the L.B. and S.C.R. station up the hill. This trap, being on the main outlet from London to the South-East corner of England, is naturally much used by motorists, and it behoves them to look after their lamps.

On the Great North Road at Finchley a trap is generally set for motorists going that way.

CASES AGAINST MOTORISTS.

Place.	Summoned for	Fine.
Bournemouth.....	Driving dangerously	£5, etc.
Welwyn	Furious driving	£10.
Ripley	(1) Dangerous speed; (2) driving recklessly ; (3) no rear light	(1) £2, etc.; (2) withdrawn : (3) 10s., etc.
Bristol	Driving dangerously	Dismissed.
Highgate.....	Beyond legal limit	40s., etc.
Kingston	Dangerous driving	£2.
Derby	No rear light	20s., etc.
Cupar	No rear light	2s. 6d., etc.

TO CORRESPONDENTS.

All communications intended for insertion in this Journal or relating to Editorial matters should be addressed to The Editorial Department, Motor-Car Journal, *39 and 40, Shoe Lane, London, E.C., and must be written on one side of the paper only. Letters must in all cases be accompanied by the name and address of the writer, as no notice will be taken of anonymous communications.*

The Editors cannot undertake to return MSS. or drawings, although every effort will be made to do so in the case of rejected communications. Where such are regarded as of value, correspondents are requested to retain copies.

THE

Motor-Car Journal.

VOL. VI.] LONDON, SATURDAY, DECEMBER 3, 1904. [No. 300.

Published Weekly by CORDINGLEY & CO., 39 & 40, Shoe Lane, London, E.C.

COMMENTS.

AS will be seen from the report on another page, Mr. W. H. Maudslay, of Coventry, has been elected chairman of the Mechanical Transport Committee of the Automobile Mutual Protection Association, whose membership is now close upon two hundred of the leading firms in the automobile industry, a fact which shows how rapidly the business has grown within a recent period. It is hoped that the regulations of the Local Government Board will be issued without further delay, so that the trade may know what they may do, and what they may not do. This is a section of the industry where Great Britain undoubtedly leads, and it is to be hoped that the Government department will not delay further progress by long postponement of the anxiously awaited regulations.

◆ ◆ ◆

Signing Licences.

THE steady growth in the popularity of motoring has not been a source of unmixed pleasure to the clerks of registering authorities, among whom is Mr. G. L. Gomme, the clerk to the London County Council. The duty of signing every licence issued in London under the Motor Car Act at present devolves on him, and some idea of the onerous nature of this task may be gathered from the fact that though the Act only came into operation at the beginning of the present year, nearly twelve thousand licences have been issued already. Many of the licences, moreover, will soon have to be renewed, and as it is important that there should be no delay in signing them the Highways Committee has decided to recommend that Mr. James Bird, the chief clerk of the department of the clerk of the Council, be authorised to sign the licences on behalf of the Council when necessary.

◆ ◆ ◆

Slower Speeds.

MISS BRADDON, the eminent novelist, who, from her retreat in the New Forest, is able to obtain some idea of the speed of the motor-car, has been writing her reminiscences. She comes to the conclusion that this is the age of locomotion, and that the chief desire of mankind is to get "from one place to another as quickly as modern science can achieve." Then follows a rapid picture of the City man of the present day who seems to spend his time in rushing from place to place, spoiling digestion and much else in the process, returning at length, "black with dust," to tell friends about the glories of an automobile expedition. But we would remind Miss Braddon that motorists do not wittingly go into danger, as her suggestion would seem to imply, and that only last week, in his exhaustive paper at the Automobile Club, Mr. Worby Beaumont urged the material advantages of a more moderate speed than makers of motor-cars have hitherto aimed at. As he pointed out, slower speeds than now practised would conduce to longevity of the car as well as to the comfort of the passengers.

Light Cars.

THE paper which Mr. Worby Beaumont contributed to the A.C.G.B.I. at last week's meeting was a careful record of the progress of the light car from the early days of Daimler, Levassor, Benz, De Dion and Bouton, and a careful examination of the principles of construction adopted in the modern vehicles participating in the light car trials It would be very interesting, and certainly instructive, if the designers and drivers of the various vehicles taking part in that event could be brought to the Club to discuss Mr. Beaumont's criticisms—from their respective points of view. In this way a really useful interchange of opinions would take place, which should have a good effect on the cars of the future.

◆ ◆ ◆

The Water Question.

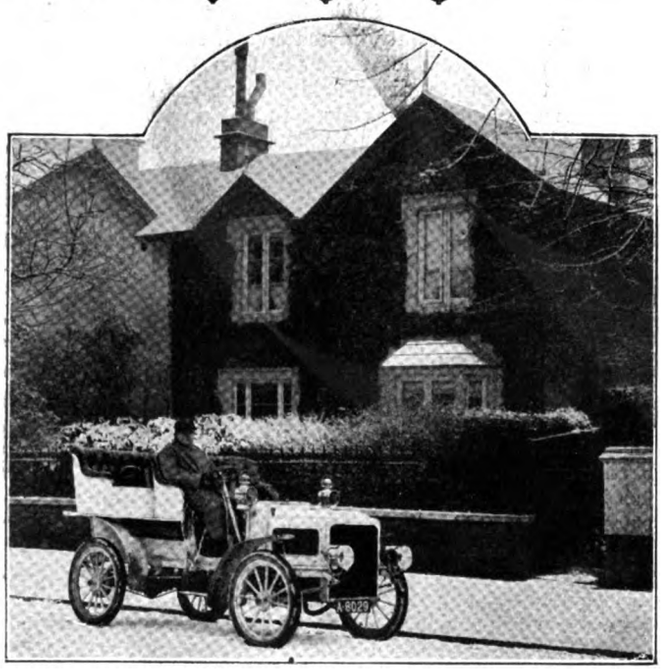
IN our correspondence columns a London motorist calls attention to a piece of extortion which we hope will receive more than passing comment. It appears that in addition to the rate for the ordinary domestic water supply, he has been charged a guinea because he happens to keep a motor-car on the premises. The water company, or, we suppose, the Water Board, acknowledges that the charge for those who keep a carriage in this particular district is 8s. per annum, 8s. being also charged for each horse. Why then should 5s. above the rate for a horse and carriage be charged to a man who owns a small motor-vehicle? There is no more washing required with the body of a motor-car than with the ordinary brougham, whilst, because the car may be of six or seven horse-power, it does not follow that its water consumption is likely to be above that of a one horse-power animal. This is one of those new problems that have arisen in connection with the development of automobilism, and, like the question of heavy motor vehicles taking water from public troughs, should have consideration from the authorities who are working with a view of helping motorists in their difficulties.

◆ ◆ ◆

Motor-Boat Club.

IT was bound to come. The rapid voyage of the motor-boat into favour with British sportsmen made the formation of a British Motor-Boat Club absolutely necessary if development is to be as rapid as the progress of mechanical power on ordinary roads. Under the chairmanship of Mr. Noel B. Kenealy such an organisation has just been favourably discussed, while a practical turn was given the debate by the appointment of a large and representative provisional committee to draw up the rules and get the matter well forward for next season. There is no foretelling the effect of the new movement on our rivers and lakes and seaside resorts. Southampton Water may become agitated with the presence of scores of speedy craft, the placid Broads of East Anglia may be disturbed as they were never startled before; Henley may see new records, and a motor-boat meet on Windermere may be accompanied with a car tour among the surrounding hills, air-ships and balloons carrying passengers over-

Digitized by Google



hill and dale far above the mountain summits. Meanwhile the Motor-Boat Club will be getting to work in a very practical fashion.

◆ ◆ ◆

The Value of Non-Skidding Devices.

THE streets of London have been strewn with snow, which, mingling with the ordinary refuse of the roads, has covered asphalte and wood paving alike with a substance of the consistency of butter, and there were many false prophets who expected to see motor-cars darting into the paths of other vehicles and generally showing a disposition towards waywardness dangerous to everyone within range of their track. But, thanks in great measure to the growing adoption of non-skidding devices, no accidents have been reported owing to this cause, and the behaviour of the hundreds of cars that have traversed the greasy London streets has afforded a demonstration of safety that should reassure those of nervous mind. The enterprise of the inventors who have seriously studied the problems associated with the skidding of cars has thus had its reward, for many who have hitherto been inclined to doubt the efficacy of such accessories are likely to become converts.

◆ ◆ ◆

Adventures in the Snow.

DURING the severe weather of the past few days some adventurous motor-car rides have been compulsorily undertaken by motorists in many parts of the country. Mr. Currer Briggs, the ex-Lord Mayor of Leeds, was among the number, and he is likely to remember an eventful ride he recently experienced in motoring from Windermere to Leeds. Silverdale was reached all right, but the snow began to cause trouble at Carnforth, and, urged by strong winds, was swept into large drifts. The first mishap occurred at High Bentham, the car becoming embedded in a snowdrift. A path was made after plenty of spade work, and the occupants of the car got away on their journey once more. They were not long in finding themselves in a worse plight. On Clapham Common the snow had obliterated all trace of the roadway, and, there being no hedge on either side, the car left the road and sank deep into another drift. Fortunately, however, a few men got the car safely on to the road again, only to encounter a third stoppage in another snowdrift. An hour's delay in the biting cold was experienced here, and, the journey resumed, all went well until near Settle the car was again stopped in a drift. This time there was no help at hand, and, the spade being broken, there was nothing for it but to rush the drift. The chauffeur backed the car and succeeded in boring a way through. Settle was reached at a quarter to five, the ride from Silverdale having taken nearly five hours. Half-frozen and hungry the party completed the journey by train, the driver remaining at Settle overnight.

◆ ◆ ◆

Scottish Experience.

MR. RONALD M'NEILL, a Parliamentary candidate for West Aberdeenshire, has also had an exciting adventure in the snow. His motor-car left Cluny Castle at mid-day on Monday week for Clatt. The layer of snow on the roads was sufficient to cause the wheels of the car to slip, and considerable difficulty was experienced in climbing hills. From Clatt the party motored to Rhynie in bitterly cold weather, and held their meeting. The following morning broke wild and stormy. All through the night and the early morning snow fell heavily, and the drifting snow made the roads almost impassable to vehicular traffic. Banks of drifted snow lay at intervals along the roads, three, four, and, at some places, six or more feet deep. Mr. M'Neill was due at Cabrach at two o'clock in the afternoon. An attempt was made to run the motor-car on the snow-covered roads, an attempt which was not unaccompanied with risk, for, in dashing into a bank of snow, the car swerved and turned, and at times almost upset, so difficult was it to steer. The car came to grief about a mile from Rhynie. Ascending a hill, it went into a snow drift and stuck there. It would neither go forward nor come back the way it went in, and there was nothing for it but to dig it out. The car returned to Rhynie, and a telegram was sent to Cabrach postponing the meeting there, as it was a physical impossibility to reach the place. From Rhynie Mr. M'Neill made an attempt to reach Huntly by motor-car. When the car left Rhynie the snow was drifting fast, and it had not got more than half a mile from the village when it stuck in a bank of snow. Helpers from a neighbouring farm, however, dug the car out. Half a mile further on the car again stuck, but it was extricated and sent on its way again. It had been deemed advisable to send on their luggage on a two-horse wagonette, and Mr. and Mrs. M'Neill and Mr. George Cruden had soon to mount beside the luggage, for about two miles from Gartly the car dashed into a heavy field of snow lying between two hedges, the drift being about a quarter of a mile in length, and from two to five or six feet deep at certain parts. The car was now almost completely buried, and the party left it there, and with difficulty reached Gartly Station in time to catch the train for Huntly.

The 4,000 miles' trial.

THE second week of the Automobile Club's 4,000 miles reliability trial of the 16-20-h.p. Martini car entered by Capt. H. H. P. Deasy was completed on Saturday, when the total distance covered was 2,300 miles. The test was an exceptionally severe one during last week, owing to the roads being covered with snow and to the intensity of the cold, which made the task of driving (shared by Capt. Deasy and Mr. E. G. Williams) not only difficult but perilous. Especially was this the case on the Wednesday and the Thursday. On the first day Capt. Deasy had to drive on the North Road for three hours in a blinding snowstorm, whilst on the following day, over snow-covered roads, Mr. Williams had to make the ascent and descent of Sunrising Hill, between Banbury and Stratford-on-Avon. The cold was so intense that the lubricating oil froze and had to be continually thawed. Despite all these difficulties the car ran with regularity and with no involuntary stops, though naturally the speed was not kept up to the legal limit. The official observers were Messrs. Basil Joy and Spong, who found the task they had undertaken not of the most comfortable character. Though the weather has been much milder this week, the thaw has reduced the roads to a very heavy state.

In the Floods.

BUT not only have light cars experienced some strange happenings; we are able to publish a photograph depicting what might almost be called the voyage of a heavy vehicle—a Coulthard lorry. This was out on test, and the driver encountered a flooded road, along which he journeyed with the water at one time over the axles of the vehicle. High tides, an exceedingly heavy rain coming down the river, and high winds were the cause of the floods, and the fact that the motor-lorry was able to make its way under such conditions is testimony to its reliability such as is not often obtainable.

◆ ◆ ◆

Application for Speed Limit at Leigh.

MR. E. P. BURD, inspector of the Local Government Board, has just held an inquiry at Leigh into an application by the Town Council to restrict the speed of motor-cars in the borough to ten miles an hour. Local motorists were represented, and Mr. Rees Jeffreys opposed the application on behalf of the A.C.G.B I. and the Motor Union. The Town Clerk said the streets of the town are narrow and have numerous by-streets running into them at right angles. Children make the streets their playgrounds, and, the footpath being small, people are in the habit of walking along the roadways. Works and collieries, also, are near the main roads, and at times the streets are crowded. The Borough Surveyor and the Superintendent of the Leigh police were called in support of the application. Replying to the supporters of the application, Mr. Rees Jeffreys said the matter was of more than local interest, for Leigh was in the centre of South Lancashire, and commanded some important thoroughfares. The tramcars that went through Leigh travelled at speeds of from 11 to 13 3-5 miles an hour, although the Board of Trade limit was eight miles. A well-defined warning of dangerous spots would be better for the motorist and the public than a ten-mile speed limit. The inspector will now report to the Local Government Board.

A Coulthard Steam Wagon traversing a road near Preston flooded by high tides and heavy rains. Although at one time the water was above the hubs of the wheels, the wagon got through without a hitch.

◆ ◆ ◆

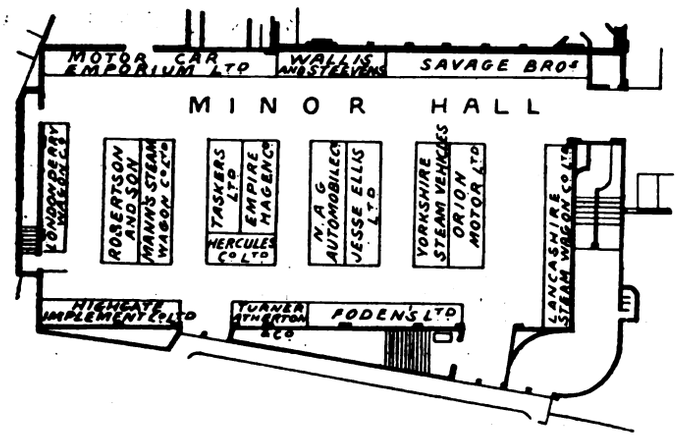
The Aero Club Banquet.

ONE of the most fashionable functions ever held at the Carlton Hotel was that held on Friday of last week, under the auspices of this Club. Nearly a hundred members and friends sat down under the presidency of Mr. Roger W. Wallace, K.C., and there was a brilliant assemblage of ladies and gentlemen, the former being perhaps in a majority, their beautiful gowns and sparkling gems setting off the sombre garments of the gentlemen. The speaking was of a high order, amongst those proposing or responding to the various toasts being Mr. Wallace, Col. Holden, Sir Hiram Maxim, Hon. C. S. Rolls, Miss Annesley Kenealy, Mr. H. R. Graham, M.P., Hon. C. A. Parsons, and Mr. Schenck. Altogether a most pleasant evening was spent.

◆ ◆ ◆

Playing with Vowels.

DORSETSHIRE is evidently a fastidious county, and local motorists anxious not to become identified with its distinguishing letters have paid their fees to the councils of other counties rather than to that of the district made famous and familiar by Thomas Hardy. But, since the reforming zeal has come over the people, why not continue it further and improve the nomenclature of some of the hamlets that nestle in obscurity until venturesome motorists go their way? The dropping of a few I's, and the substitution of any other vowels, preferably, of course, "o" or "u," would effect a great change and save the looks of surprise and wonderment that must often arise when these strange-sounding names are heard or seen for the first time.



Parochial Visitation by Motor-car.

THE Bishop of Bath and Wells journeyed to Taunton the other day in his motor-car to open a bazaar at which he and Archdeacon Askwith made some of the usual jokes with regard to the automobile. On the same day, the Bishop of Thetford commenced a parochial visitation from King's Lynn in a motor-car lent him for the purpose. It would appear from these two instances, as well as several others which have been recorded in our columns from time to time, that the day is not far distant when the motor-car will become a familiar means of episcopal pilgrimage, just as General Booth lately popularised it in a good many towns throughout the country. While mentioning this subject, we would recall one or two interesting facts obtained from Commissioner Nicol, who accompanied the General of the Salvation Army on his memorable tour. As we surmised at the time, the idea of utilising the motor-car was suggested by the King on the occasion of his interview with General Booth. The tour was carried out at a cost of £500, and, during the journey of 1,300 miles from Land's End to Aberdeen, the collections taken on route amounted to £1,500. just over a sovereign a mile. Evidently all sects and denominations are recognising the utility of the motor-car as well as the economy of time that is associated with its use.

The Exhibition of 1905.

THIS week we are able to publish the plan of the Minor Hall of the Agricultural Hall, London, where next year's international automobile exhibition will be held. From this it will be seen that the whole of the space in that section of the display has been let to firms engaged in the construction of

heavy motor vehicles, and that the thoroughly representative character of the Exhibition is already assured. Spaces in the large hall are being rapidly taken by firms engaged in that branch of the industry devoted to lighter vehicles, and plans of that important department can now be obtained for intending exhibitors who have not yet taken space from the offices of the Exhibition, 39-40, Shoe Lane, London, E.C.

◆ ◆ ◆

A Glorious Week-end.

ALTHOUGH dull and misty in town and foggy in South London, yet towards Sutton the atmosphere cleared; the roads were frozen hard and the trees covered in hoar frost, affording a picturesque sight now rarely seen in Great Britain. The view from Reigate Hill was grand, the sun was shining, and the snow was glistening like diamonds, the green patches forming an emerald setting only to be seen to be appreciated. Cars innumerable were on the road, and rarely have we seen the Brighton road so full of traffic, both vehicular and pedestrian. Brighton itself was bathed in sunshine, and the queen city of the South never looked fairer. The "Old Ship" Garage was, as usual, crowded to its utmost extent, and cars had to be left standing outside the hotel. Inside all preparations had been made for the accommodation of visitors, and those who were fortunate enough to have "window" tables found it most interesting to see car after car, with its four and five passengers, drive up to the hotel, disgorging the ruddy and happy passengers, most of whom were ladies. A run up the Front showed that other hotels were all well favoured with motoring guests, as proved by the cars outside, and it appeared to us, that if there were no motorists, the various Brighton hotels, nearly all excellent, would have fared badly indeed. A glorious run back was enjoyed, but care had to be exercised, as there were a lot of police on the road, mostly in couples. The air kept clear until near Streatham, when the fog zone was reached again, and lamps had to be lighted just after four o'clock.

Mem.—Motor-cyclists and others have taken to covering their ears, and as they do not seem to imagine there are vehicles behind them, they never look round, great inconvenience being consequently caused to other users of the road.

◆ ◆ ◆

Attempt to close Grove Hill, Harrow.

ON Tuesday the Local Government Board inquiry into the application to close Grove Hill, Harrow, to motorists was held by Mr. E. P. Burd. Mr. W. G. Austin, deputy-clerk of the Middlesex County Council, presented the case in support of the application. The council were of opinion that there would be no hardship whatever in requiring motorists to use Peterborough Road as an alternative route. The gradients of Grove Hill ranged from one in eight to one in twenty; the length of the road was only 1,860 feet, and the width varied from between fifteen and twenty feet. Peterborough Road, which commenced at the same point, and which had been made only a few years ago at a considerable cost, had no such steep gradients, and its length was only 2,060 feet, or about 200 feet longer to traverse than the dangerous hill. Then, again, at the foot of Grove Hill was a road running at right angles, thus constituting a really dangerous point not only to motorists travelling at high speed but to people approaching the foot of the hill. In 1899 a motor-car was wrecked at the bottom of the hill, two people being killed; and on Easter Sunday last another disastrous accident took place. Mr. W. Rees Jeffreys led the opposition, and the inspector will now make his report to the Local Government Board.

◆ ◆ ◆

Why Oppose?

IN connection with this particular case, it might have been well had the opposition been withdrawn, for there seems to have been some ground for the remark of the deputy clerk of the Middlesex County Council to the effect that the notice of objection was of the stereotyped character. The Automobile Club, the Motor Union, and the National Cyclists' Union seemed to have nothing to urge against such restrictions, he reminded the Inspector, but a claim to absolute freedom to go where they liked. Grove Hill has been notorious on account of its accidents, and one witness testified to the fact that 300 accidents, mostly to cyclists, had taken place on the hill during the last decade. An alternative route was suggested, which had no steep gradients and which is only about 200 feet longer to traverse. In view of this alternative it would have been good policy for the Motor Union to have fallen in with the proposal, and thus proved that they do not oppose everything for the sake of opposition—an impression sedulously cultivated by opponents. Here was a case of admitted risk and danger; an alternative route, involving no hardship, was suggested, and it would have been a gracious act if those responsible for the Club's policy had, by making no official opposition to the proposal, shown that where real danger is provable they are willing to acquiesce in anything reasonable.

◆ ◆ ◆

A Well-Fitted Car.

CAR No. A 1946 is a bit of a curiosity, and should any of our readers see it stationary in the street they should take a glance at its various fitments. First there is the folding glass screen (illustrated in our columns last week) and five powerful lamps lit by acetylene in the liquid form, which Messrs. Dunhill, Limited, have lately introduced. A "dog frightener" is worked from the dashboard, this consisting of an apparatus into which the exhaust is directed. Then there is an electric light so fixed that the clock face can be seen on dark nights, and, altogether, this particular vehicle is unique. A new horn has just been attached. This is to be worked by a pump, and instead of pressure being applied to a bulb, all that is necessary is to play a couple of stops similar to those on a cornet, when musical notes of a piercing tone are produced. They are a strong contrast to a wheezy horn, and the new device, we were informed by Messrs. Dunhill's representative when we were attracted to the car by the novel noise the other day, is proving popular, although only just introduced to the public.

THE Lanchester Motor Company, Limited, has been registered with a capital of £50,000 to acquire the undertaking of the Lanchester Engine Company, Limited. The first directors are Messrs. C. V. Pugh, J. V. Pugh, J. S. Taylor, J. Whitfield, and T. H. Barnsley.

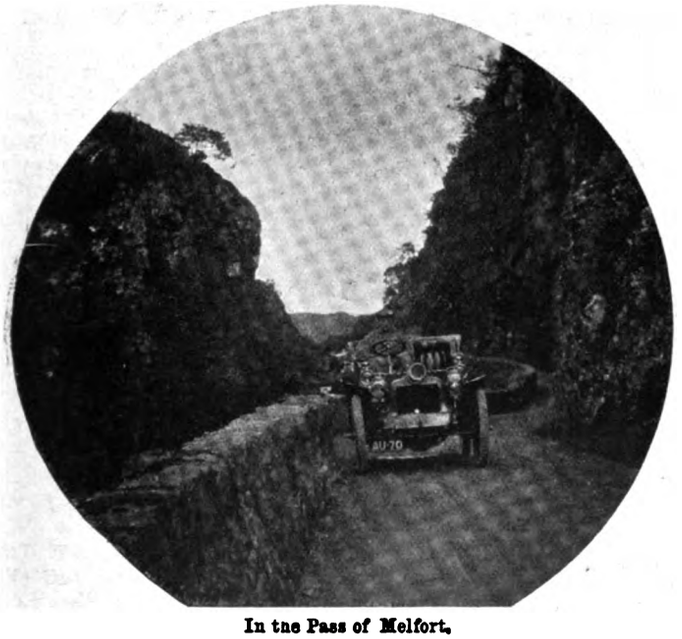
A TOUR IN SCOTLAND.



THE complaint of some of the railway magnates of Scotland that many of their whilom patrons are deserting the steel track for the common road is, doubtless, well founded. Every year sees a larger number of motorists from south of the Tweed advancing beyond Edinburgh, and finding

At John o' Groat's.

delight, not in going from place to place according to well-regulated time-table, but in touring as they please along some of the famous Scottish roads.

One of these motorists—and, as we have said, their numbers are a growing band—is Mr. Charles Hardy, of Bulwell Hall,

In the Pass of Melfort.

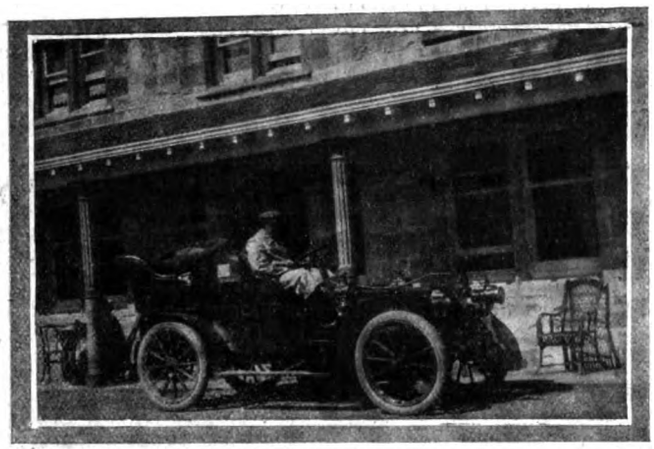
Nottingham, who for the last three summers has enjoyed the delights and the adventures incidental to a motoring tour in the Highlands. In 1903 he went northward to John o' Groat's, and towards the end of last July set forth, with his brother, on his 16-h.p. Georges Richard-Brasier car with the idea of renewing acquaintance with some of the scenes that had become familiar. From the city of the great market square and many lace factories he went by the Great North Road, touching at Newcastle, Berwick, and Edinburgh, where a few days' sightseeing added interest to the journey. Then by way of Stirling they went to the Trossachs, revelling in the glorious scenery and finding new vigour in the air. Alas! the road from Callender to the Trossachs—a narrow and dangerous one, be it faithfully recorded—is now closed to motor-car traffic, so that Mr. Hardy's third visit to that region will probably be the last—unless some enlightened Scots, recognising the prosperity that is associated with a goodly company of motorists, do something to ensure the provision of better roads in the district.

From the Trossachs our motorists went by Lochearnhead and up Glen Ogle through Shillin, and then had a glorious run of twenty miles along Loch Tay to Aberfeldy. Soon after, at Ballinluig, they struck the main road from Perth to Inverness, and the way then lay through the lovely scenery associated with the names of Blair Athol, Killiecrankie, and Pitlochry. To Inverness was a long pull from the latter place over the Grampian hills, by Dalwhinnie, Kingussie and Avienmore. Inverness is a convenient halting place for travellers by road in the north of Scotland, and there Mr. Hardy enjoyed a stay which afforded opportunity of realising the variableness of Nature.

The run to John o' Groat's was along the Cromarty and Dornoch Firths via Tain, Dornoch, Golspie and Helmsdale,

The River Garry, near Invergarry.

followed by the long dreary climb over "the Ord o' Caithness," and the deep descent into Berriedale. From the latter place a steep hill leads the way through Wick to John o' Groat's.



Returning the same way they drove *via* Thurso and Reay, and down to Helmsvale alongside the Hallivale and Helmsdale rivers. There is a very comfortable hotel at Golspie, where they stayed several days.

From there the route to Inverness was the same as going North. From Inverness they drove all alongside the Caledonian Canal to Fort Augustus, the scenery by the water from this road being very fine indeed. These roads are very tortuous and rather hilly, while some very dangerous corners have to be carefully negotiated. They left the canal banks at Fort Augustus and went to Invergarry and stayed there about ten days. The scenery all round about is acknowledged to be some of the wildest and grandest in the Highlands, and the road—about twenty miles—to Glenquoich and Loch Hourn especially striking. The hotel at Invergarry is delightful, and seems to improve with acquaintance. From thence the way was down by Fort William and Ballachulish (ferry) and through Glencoe and across to Oban. After staying a couple of days there, the route lay through the Pass of Melfort and Ford, where they struck the road up alongside Loch Aire with more delightful scenery. Eventually

Digitized by Google

they went over the hills and down to Inverary on Loch Fyne. Here was a memorable run all along the loch to Cairndow; then came the bad and rough climb up the "Black Spout" and over by "Rest and be Thankful," with the long and dangerous twisting descent to Arrochar, on Loch Long, and from there across to Tarbert, on Loch Lomond. From there they drove all along Loch Lomond and on to Edinboro' via Glasgow.

After staying a day there they came south to Carlisle and over Shap, with rain pouring heavily and a heavy fog adding to the experiences of the journey in August. Then through Ken-

The Car leaving Invergarry.

dal, Skipton, Bradford and Doncaster, and again to Nottingham. In all, Mr. Hardy and his brother were away just a month. They covered about 1,650 miles without the slightest engine trouble, nothing was done to the motor from start to finish, and, with the exception of lubrication and cleaning, their only troubles were two punctures, one near Berwick and one at Aviemore. Fortunately the weather, until the return to England, was almost ideal for touring, and the trip adds yet another proof of the value of the motor-car for exploring the scenic beauties of our native land.

HILL-CLIMBING IN AUSTRALIA

MR. CHARLES W. BENNETT, of Melbourne, Victoria, recently made an interesting trip on a 10-h.p. De Dion car, when, with his friends, he journeyed to the Kunagong Heights, sixty-two miles from Sydney. Five miles from the heights there is a grade of one in thirteen to one in six, finishing with a stretch of 1,330 yards ranging from one in six to one in three and-a-half. When he arrived at this point, the engine stopped, due, as was eventually discovered, to there being no petrol in the carburettor. Mr. Bennett filled up the tank full, and made another attempt at the hill. He got a little further, but again found the grade too steep to allow petrol to flow into the carburettor. He again ran the car back, but this time fixed a rubber tube between his legs on to the petrol tank-stopper and started again, blowing down the tube the whole way, causing a force feed. He had to dismount his passengers for the final struggle, but succeeded in reaching the top.

IN connection with the forthcoming Salon in Paris an International Congress on Automobile Navigation is to be held from the 19th to the 24th inst.

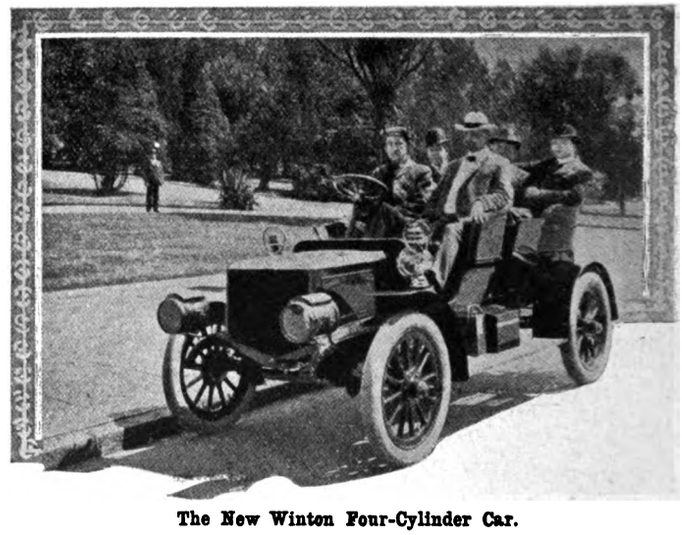
COUNT E. KNUTH has been elected president of the Danish Automobile Club in succession to Baron Blixen-Finecke.

MESSRS. A. W. GAMAGE, LIMITED, of Holborn, have secured the sole agency for the Durkopp motor-bicycles.

THE "Auto" Engineering Company have every facility for the repair of motor-cars at the North Street Garage, Leeds.

MR. DUGALD CLERK is to deliver a series of lecture on "Internal Combustion Engines" at the Society of Arts in February next.

CONTINENTAL NOTES.



The Gordon Bennett Cup Race.

M. Quinones de Leon has returned from his prospecting trip over the proposed circuit in the Morvan Mountains, but has reported unfavourably on the roads of the district, which, though smooth and hard, are narrow, while the hills are terrific and the turns too sharp to be taken at any speed. The Sporting Committee of the A.C.F. has accordingly decided against the proposed Morvan route, at least for the present. M. René de Kynff also reported on the roads round Vichy, of which he was unable to give a very favourable account. The Committee eventually decided to ask both gentlemen to prosecute their investigations in different parts of France. Since then M. Michelin has suggested a new course for the Cup race. It starts near Clermont Ferrand, where the Michelin tyres are made, and passes through Pontgibaud, Herment, Bourg-Lastic, Laquenille, and Rochefort. A good deal of gossip is taking place with regard to the horse-power of the racers the different French firms will build for the 1905 Gordon Bennett race. It is stated that Messrs. De Dietrich's vehicles will be of 140-h.p., those of the Gobron Brillié Company 120-h.p., while the Richard-Brasier Company will be content with 90-h.p. motors. A report to the effect that the Peugeot Company will compete in the eliminating contest for the French team has been denied.

◆ ◆ ◆

The Paris Salon.

Ere the next issue of the *Journal* appears the great annual *Salon* of automobiles in Paris will be in full swing. For over a week a vast army of men have been at work fitting up the stands, the heating stoves, and installing the thousands of electric lamps by which the great building is illuminated. It goes without saying that this show will eclipse everything else that has preceded it. The difficulty of finding sufficient room in the Grand Palais last year to accommodate all the exhibitors compelled the organising committee to provide for an overflow, and they have therefore secured the Horticultural Palace in the Cours La Reine, only a few steps from the Grand Palais. All the machinery in motion, as well as the motor-boats, will be rele-

The New Winton Four-Cylinder Car.

gated to the *Serres*, as the buildings are known, and as the lower part of the building is on a level with the River Seine, it is intended to give buyers an opportunity of testing the boats.

◆ ◆ ◆

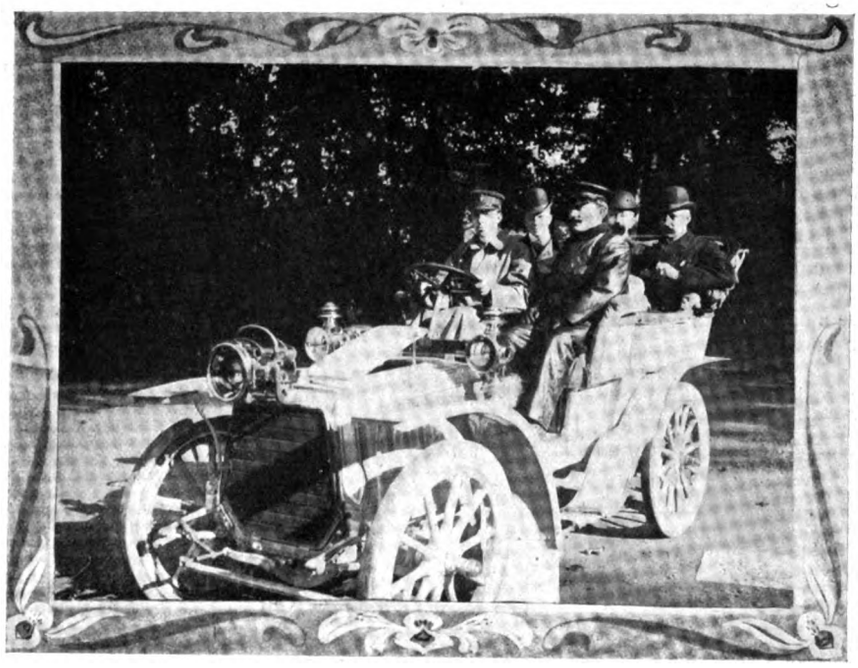
The Motor-Car Movement in Hungary.

The Hungarian Automobile Club, which was inaugurated six years ago, now numbers ninety members, mostly owners of cars. There are, however, as many more owners of cars in Hungary who are not members of the club. The second Hungarian Automobile Exhibition is to be held in Budapest from the 7th

Digitized by Google

to the 21st May next, at which many well-known makers have already announced their intention of exhibiting. In connection with the show, a hill-climbing contest and a gymkhana are to be organised.

◆ ◆ ◆



Public Services in Italy.

Public services of motor-cars have lately been established between Pitigliano and Orbetello and between Pitigliano and Orvieto, near Florence. The vehicles, which were supplied by Messrs. Delahaye and Company, are of 16-h.p. and have accommodation for twelve passengers.

◆ ◆ ◆

The Herkomer Trophy Competition.

The Herkomer International Competition for touring-cars (at least four-seated), which is being arranged by the Bavarian Automobile Club in co-operation with the German Automobile Club, is to held in the Munich district in August, 1905. According to the new rules which have just been issued the competition is open to the members of those clubs that are affiliated with the German Automobile Club. The entrance fee is £15, and the last date for entries is the 31st May, 1905. The Herkomer prize is an artistic trophy wrought in fine metal, and to become the property of any competitor must be won twice within three years. The second and third competitions are to take place in the country of the previous winner under the management of the club to which the winner belongs. If none of the competitors win the prize twice within the three years, it is to be drawn for by the three winners after the third competition in order to decide the definite holder of the prize. The winner in each year will in addition have his portrait painted by Prof. von Herkomer. Besides these the following prizes are offered: (1) Prize of honour presented by H.R.H. Prince Ludwig Ferdinand of Bavaria (object in silver, value £50) and given by the Bavarian Automobile Club to the touring car which develops the best average time in the Kesselberg and Forstenrieder Park trials. If the results of several cars should be exactly the same, the prize will be awarded to the first car in the hill-climbing competition. (2) Honorary prize (object in silver, value £50) given by the German Automobile Club for the most handsome and most practical coachwork. (3) Honorary prize dedicated by Dr. Magin and given by the Bavarian Automobile Club (work of art by the sculptor Mr. von Gohsen, value £100) to the winner in the Herkomer trophy competition of 1905. All the cars entered for the competition will be exhibited in Munich for one day and valued as to the beauty and practical use of their body-work. On the second day the hill-climbing capabilities of the cars will be tried on the Kesselberg, 7 kilometres; on the third day their speed on level ground, 6 kilometres in the Forstenrieder Park, near Munich. On the fourth day the touring trial over a distance of 900—1000 kilometres will be commenced. The programme of this is:—First day, Munich—Bruck—Augsburg—Ulm—Tubingen—Baden-Baden. Second day, Baden-Baden—Stuttgart—Nuremberg. Third day, Nuremberg—Regensburg—Munich. An observer will accompany each car during the whole of the touring trial, and will note the number of involuntary stoppages, their cause and duration.

King Alfonso of Spain has, much against the will of his royal relatives, recently undergone a course of instruction in motor mechanics, and is now not only an apt *chauffeur* but is stated to be capable of making roadside repairs. Our illustration shows the young King at the wheel of his Panhard.

◆ ◆ ◆

The Bleichroeder Race.

Immediately after the speed-trials of the touring cars for the Herkomer competition, the Bleichroeder race arranged by the German Automobile Club together with the Bavarian Club will take place on the Kesselberg and in the Forstenrieder Park, the first racer being started when the last touring car finishes. The race will extend over two days:—First day, Kesselberg hill-climb (7km.); second day 6 km. run in the Forstenrieder Park. The best average time will decide the event, which is international and open to all classes of racing cars up to 1,000 kg. The drivers must be members of one of the above-mentioned affiliated clubs or of the German Automobile Union. The entrance fee is £15, and the last date for entries, 10th June, 1905. The first prize is £400 (in cash), and the second prize £100, offered by Baron James Bleichroeder, and given by the D.A.C. Full particulars of both events can be obtained from the Secretary of the German Automobile Club, 4A, Sommerstrasse, Berlin, or to the Secretary of the Bavarian Automobile Club, 98, Turkenstrasse, Munich.

◆ ◆ ◆

Heavy Vehicle Trials in France.

At the meeting of the Competitions Committee of the A.C.F. last week it was decided to hold, about August, 1905, (1) a reliability trial for public service vehicles which will be run throughout the chief districts of France, fetes and exhibitions being arranged *en route* at various points, and (2) a trial of delivery vans under similar conditions.

◆ ◆ ◆

British Capital in the French Industry.

A feature of the French motor-car industry at the present time is the support which is being given to it by English capitalists. As is well known, the Darracq factory is owned by a British company. It is now announced that a new company is being formed in London to take over the sales department of Messrs. Renault Freres, the latter devoting their energies entirely to the production of cars. It is also rumoured that some English capital has been invested in the Rochet-Schneider Company, to enable the latter to extend its operations. A company has also been formed in England to develop the Hautier car.

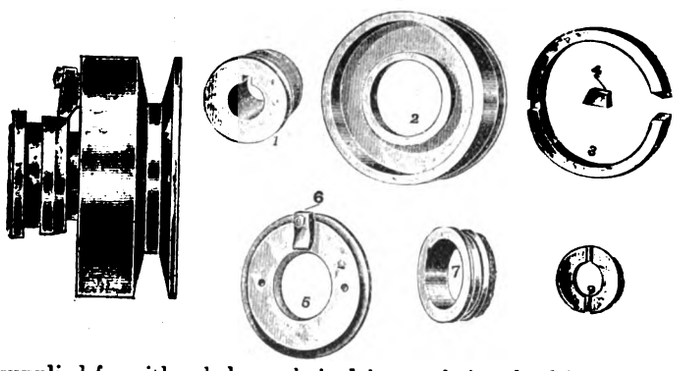
MOTOR CYCLING NEWS.



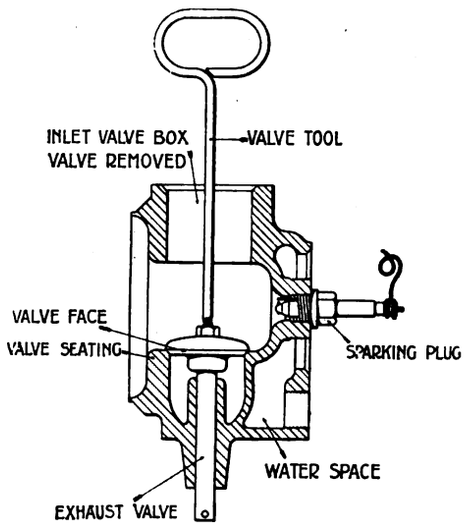
MR. G. C. GNAPP, of Colombo, Ceylon, sends us particulars of a run on a Rover motor-bicycle he recently made from that city to Kandy and back, in company with a party of friends mounted on cars. Notwithstanding that bad weather was encountered, the roads being inches deep in mud and full of ruts, the Kadugannawa Pass was successfully mounted without pedalling, and the journey accomplished without trouble of any kind.

◆ ◆ ◆

THE prospects of a motor-cycling club for Cardiff are bright. A large meeting of those interested in the movement was held at the Rummer Hotel, Cardiff, on Monday, under the chairmanship of Mr. Charles Williams. It was agreed that the club be called the "Cardiff and District." A temporary committee was formed, and it was proposed that the subscription be fixed at 10s. 6d. for the first year, including the badge. A further meeting will be held on the 12th inst.

◆ ◆ ◆

A NEW clutch for use on motor-cycles, to give a free engine when desired, has recently been introduced by Richards' Beau Ideal Cycle Company, Limited, of Heath Town, Wolverhampton. The complete clutch and pulley is shown in the left of the illustration and the details to the right. Referring to the latter, the part marked 1 is the sleeve, which is fixed to the engine shaft on which the pulley and clutch drum, 2, revolve freely. Inside the drum is an expanding ring, 3, the expansion being effected by a wedge piece, 4, which, when not wedged home, lies in idle contact with the split chamfered ends of the expanding ring. An outside plate, 5, is fixed to the sleeve, 1, and so rotates with the engine shaft. On this plate a small lever and set screw, 6, are fixed, the set screw being intended for adjustment of the lever as wear takes place. On the sleeve, 1, is a loose collar, having a groove for the controlling fork and a taper coned nose; the moving of this coned collar actuates the short lever, 6, which in turn forces the wedge, 4, against and between the split ends, the ring expanding it in turn against the inner surface of the clutch body, the whole becoming a fixture with the engine shaft. By withdrawing the collar, the spring at once contracts, releasing the clutch pulley, and rotates loosely with the parts attached to the engine shaft, the pulley remaining idle. The device can be



supplied for either belt or chain drive, a chain wheel in the latter case taking the place of the grooved pulley.

A SPEAKER at a meeting in connection with the parish council of Drumgeith, N.B., has declared that no motor car should be allowed to go at a greater pace than a good horse. Why not say that no horse shall go quicker than a fairly progressive motor-car?

MESSRS. BEANLAND, PERKIN AND COMPANY, Leeds, have sent us a small sample tin of a new preparation known as Gre-Solvent they are introducing for removing grease from the hands. The preparation is claimed to contain no acids or sand, and, judging from the brief trial we have given it, should prove useful to those motorists who look after their cars themselves, as by its use grease and oil can be quickly removed from the hands.

SOME USEFUL NOTES.

THE exhaust valve on the engines on Wolseley cars is fitted on the under side of the combustion chamber, and is "built up"; it consists of a mild steel spindle, to which a cast iron head is screwed and locked by a patent method. This valve requires considerably more attention in the matter of grinding than the inlet valve, as it is subjected to very great heat, and any particles of burnt oil in the exhaust gases are liable to pit the face of the seating. The method of "grinding in" this valve is to remove the inlet valve and box; the exhaust spring must then be unshipped and the valve removed through the inlet valve hole. A special tool is provided for grinding-in purposes by the Wolseley Company. As will be seen from the accompany

METHOD OF GRINDING IN EXHAUST VALVE

ing diagram, this should be screwed into the head of the valve; a paste, composed of flour, emery and oil, is then put on the face, and the valve is lowered into position again. With a light pressure it is then ground on to its seat by twisting first one way and then the other, the valve being occasionally lifted and moved round about a quarter turn, and the operation repeated, so as to ensure the valve and seat facings being equally true all over.

◆ ◆ ◆

AFTER a minute or so the valve should be taken out and cleaned, and to see if the surface is quite bright and smooth all over. If this is not so, the grinding must be continued till all the "pits" are ground out, and there are no discoloured places on the valve face. It is advisable to true the exhaust valve up in this way after every 500 miles, rather than to leave it until it gets very bad. The stem of the valve should also be examined to see if it is working quite freely in the guide-hole. To ensure the best results from the motor it is perhaps advisable to replace this valve with a new one every six months. When the grinding operation is over, the emery and oil must be removed from the various parts by well washing out with petrol.

◆ ◆ ◆

THE inlet valve will need very much less grinding in, the operations being the same with the exception that, as the valve stem projects through the casing sufficiently, it may be used to turn the valve instead of using a special tool. When replacing the inlet valve, the spring must be carefully adjusted to its former position.

◆ ◆ ◆

THE water in acetylene lamps is best preserved from freezing by dissolving calcium chloride in it. But if this precaution, is not taken and the water is frozen, a little saliva on the carbide will produce enough gas to light it and thaw the water, and so allow a permanent light to be obtained.

Digitized by Google

THE ROVER 8-h.p. LIGHT CAR.

(*Concluded from page* 795.)

The mixture is furnished by one of the Rover automatic carburettors, of which a sectional illustration is given in Fig. 1. The apparatus has been designed by Mr. E. Lewis, whose object has been to obtain the advantages of an automatically-controlled air supply with the absence of any integral parts likely to prove troublesome of adjustment, or subject to derangement by vibration. The casting consists of two chambers linked by a small trunk connection, the one, A, being the customary float feed chamber common to most types of spray carburettors, the other, B, the mixing chamber or carburettor proper. It will be noticed that on the petrol lifting the float in the chamber A, the latter acts on the balanced arms just above the top of the float, causing them to depress the needle valve and restrict the flow of the spirit. The body, B, comprises two elements, and is fitted with a brass liner, which contains the plug C. To the upper portion of the latter is attached a piston E, which is kept staunch by a packing ring W. The piston is provided with a series of Λ shaped ports, H, and is attached to the plug C by means of a screwed joint. The rod I

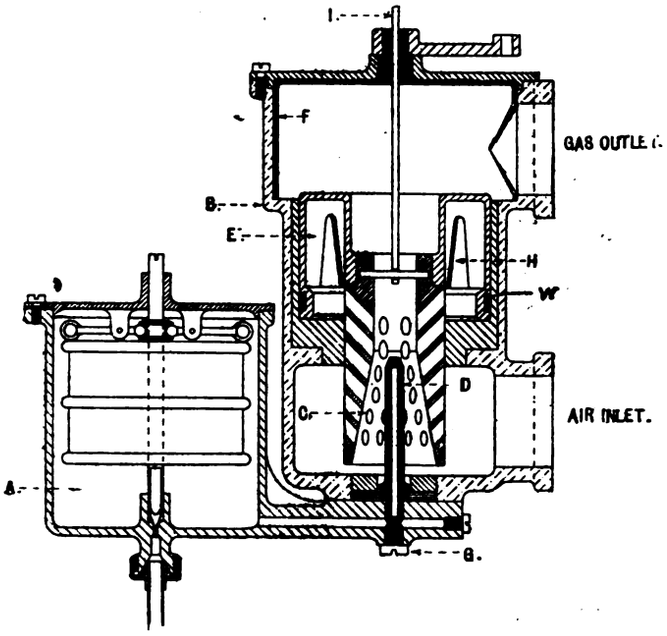


Fig. 1.—Section of Rover Carburettor.

A. Float feed chamber.
B. Carburettor body.

I. Indicator.

is attached to both by means of a coupling piece at the base, the upper end passing through the cover. The operation of the moving parts C and E is controlled by the suction impulse of the motor on the one hand and by gravity on the other, the plug C being made sufficiently heavy to ensure its return to the normal position without the aid of a spring. The effect of the suction influence of the engine may be grasped by noting the elongated perforations in the plug C, where a corresponding series of air passages communicate with the air inlet chamber. Thus according to the measure of vacuum in the mixing chamber, which will vary with the speed of the motor, the relative positions of the plug and piston with the corresponding air inlet passages will determine the greater or lesser amount of air admitted. The perfect action of the carburettor is largely due to the careful proportioning of these air passages, hence the shape of the openings themselves, and the neatly arranged method of grading their capacity. The throttle valve F is situated at the top of the carburettor, and is controlled by means of a lever. The air for both the primary and auxiliary supplies is taken in at one source, the latter being delivered through the triangular openings or ports H in the piston E.

Passing now to the clutch, this is also of a distinct and novel character; it is of the metal to metal, type and is contained in an oil-tight aluminium case attached to the side of the crank chamber. As will be seen from Figs. 2 and 3, the body of the clutch —which is attached to the rear end of the crank shaft—is a bell-shaped casting N, provided with a flat machined face P, against which a flat turned disc O is placed, this disc having a square hole in its centre boss, which is a sliding fit on the squared end of a shaft T communicating with the gear box. On the back face of this disc is situated another cast disc provided with three bracket

arms, which are in turn connected to a sliding sleeve by three levers. The top ends of these levers above the bosses are each provided with a ball-shaped projection, which engages in a double-flanged groove, turned on the inner face of a kind of screwed thimble S, which in turn screws into the mouth of the bell clutch body. The sliding sleeve has two grooves turned in its face, the rear groove accommodating a fork lever R, which is connected with the clutch pedal, while the forward groove in the sleeve receives the long end Q of the three levers. By this means and the force of a helical spring W behind the sleeve, the latter is projected forward, carrying the levers with it, which, as the three clutch levers are fixed in the recess at their ball ends, also

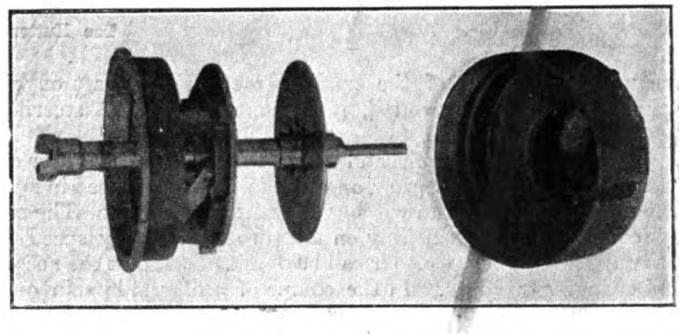

Fig. 3.—The Rover Clutch.

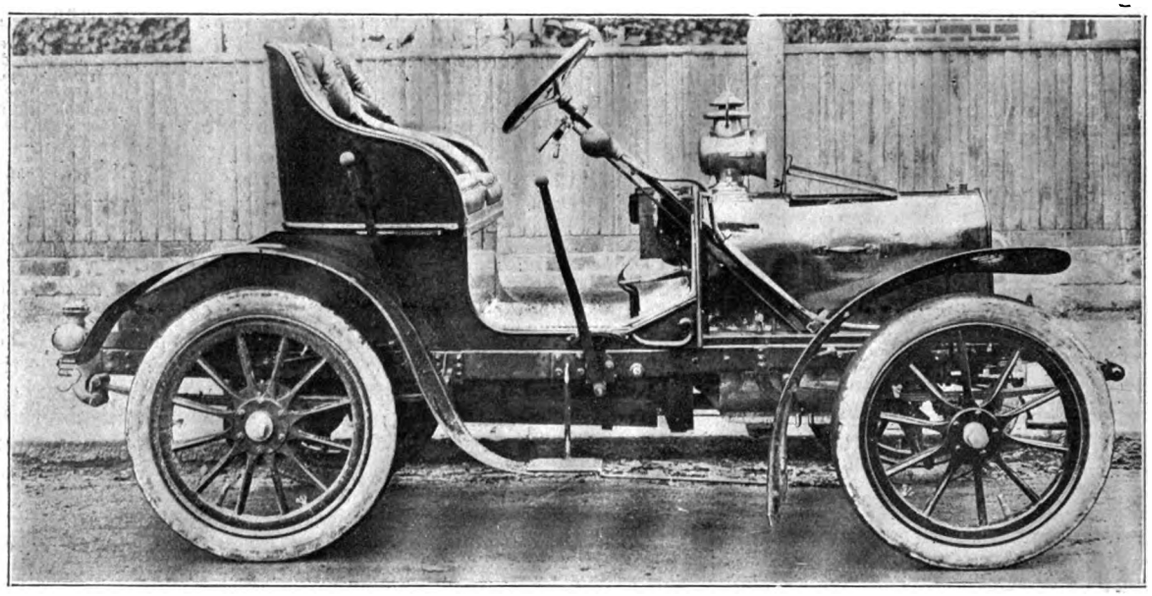
forces the bracketed disc forward against the sliding flat disc, squeezing the latter between its own face and that of the bell body face. The advantage claimed for a clutch of this type is that it is not only positive on account of the great pressure and double grip, but on withdrawing and restarting the grip is easy and gradual on account of the oil which accumulates between the faces when open, and which, in the process of being squeezed out again by the spring pressure, obviates any tendency to violent gripping of the clutch.

The change-speed gear is of the sliding pinion type, giving three forward speeds and one reverse, the top speed being direct. The single lever which operates the gear is attached to

Digitized by Google

a sleeve on the steering pillar; at the extremity of the sleeve, and extending towards the dash frame, is another arm, at the end of which is a roller which engages with half-round slots, representing the various speeds and neutral notches in the quadrant which is attached to the dash frame. The cardan shaft forms practically a continuation of the gear driving shaft. At the extremity of this shaft is fixed a bevel pinion, which meshes with a large bevel crown wheel attached to the differential gear box of the back axle. The latter is of the usual type, running on ball bearings, and enclosed in an extra large diameter tube.

The rear wheels are each provided with metal to metal band brakes on large size drums, operated by a foot lever through an intermediate compensating rod, by means of which equal braking pressure is applied to both drums. The front axle is built up of 1¾ in. diameter steel tube; the steering pivots are cupped out at the top and bottom for the reception of a large diameter steel ball in each, which balls are in turn held in place and adjusted by cup-ended set-screws. The steering column is attached to the engine frame-work. At the extremity of the column a double wire cable is wound, the ends of which are in turn attached to the steering arms on the front wheels, and maintained in proper tension by stiff spiral springs arranged at the points of attachment. On account of the small diameter of the part on which the wire cables are wound, it is claimed that the steering is practically irreversible.



The engine, clutch and transmission gear are lubricated through a common reservoir, and a half pint of oil poured in is sufficient for a 100 miles run without any further attention. The motor is controlled almost entirely on the throttle, and any speed from five to thirty miles per hour can be obtained without the necessity of changing the gear. In the course of a fifty mile spin on the car recently we had an opportunity of noting its smooth running qualities, and the action of the motor when working as an air compressor; it appears to work smoothly and not to strain the car; it is sufficiently powerful to hold the vehicle on a gradient of one in six. We may add that the weight of the car ready for the road is 10½ cwts.

It has been decided by the Continental Caoutchouc and Gutta-percha Company to form an English company, which will bear the name British Continental Tyre and Rubber Company. Besides their motor tyres, the company will also deal in all kinds of mechanical rubber goods, and will manufacture and repair tyres in their London works. The management will be the same as has heretofore conducted the business.

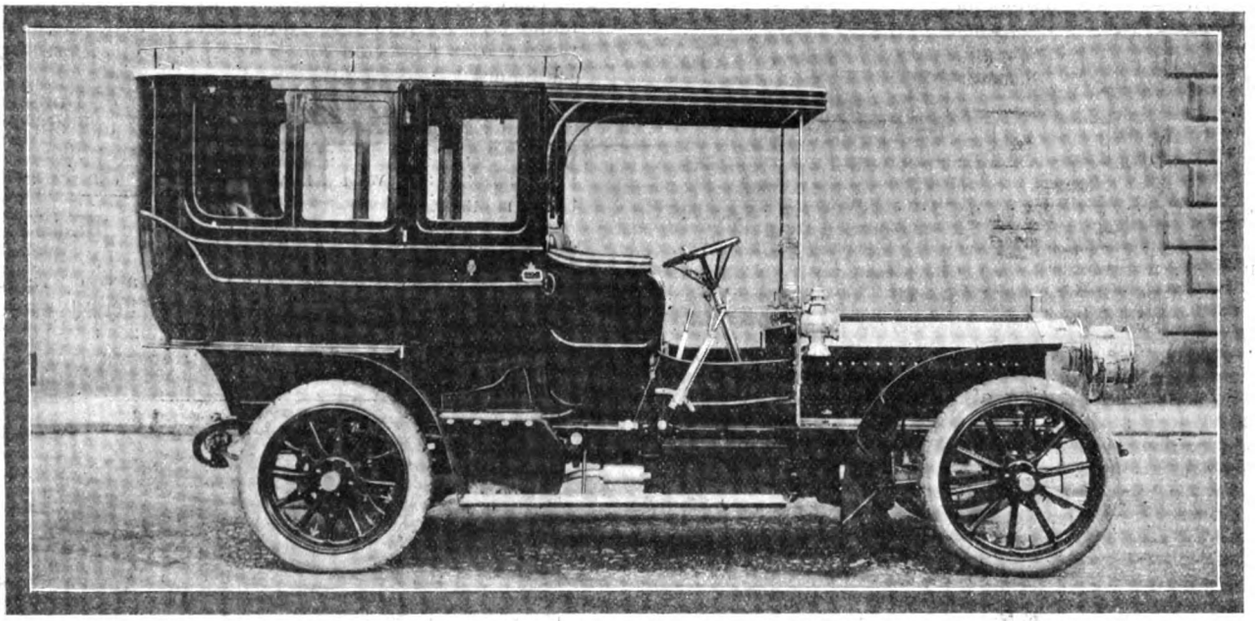
THE HUTTON LIGHT CAR.

THE other day we had an opportunity of inspecting the first of a new type of light car Messrs. J. E. Hutton, Limited, are putting on the market. As will be seen from the illustration, the vehicle has a very smart and trim appearance. The frame is of pressed steel construction; the motive power is supplied by one of the Hutton four-cylinder engines, which, while rated at 12-h.p., develops up to 14-h.p. The cylinders are 3 in. diam. by 3½ in. stroke. All the valves are mechanically actuated, and the usual high-tension system of ignition with coil and accumulators is employed, the contact maker being located in an accessible position in front of the car. No pump is used in connection with the water circulation, this being on the gravity or thermo-syphon system; a honeycomb radiator with draught-inducing fan serves for the cooling of the water. The mixture is furnished by a carburettor of unusually small dimensions, and instead of it being placed under the bonnet close to the engine, is located under the footboard. The speed of the engine is controlled between wide limits by means of the ignition and a foot-controlled throttle valve.

From the motor the power is transmitted through a cone clutch of the internal type to a gear box comprising a train of sliding pinions giving three speeds forward and a reverse, all controlled by one lever and having a direct drive on the top speed. From the gear-box the power is conveyed through a cardan shaft and bevel gear to the rear live axle. A pedal actuates a powerful band brake at the rear end of the gear-box, while a hand lever controls internally expanding brakes working inside drums attached to the hubs of the gear wheels. Altogether the new car, which is British built throughout, is on very smart lines; complete, ready for the road, it weighs as a two-seater only 11 cwt. In place of the sloping tool-box at the rear, a tonneau can be fitted, converting the car into a four-seater. Mr. Hutton has recently submitted the first of these new cars to a prolonged test, as a result of which it has been decided to take in hand the construction of a series.

The Hutton Four-Cylinder Light Car.

THE Board of Agriculture have issued a folding pocket map of Plymouth and the surrounding district on the scale of two miles to one inch. It has the hills shaded, woods coloured green, roads sienna, water blue, and contours brown; the bolder slopes are brought out by stipple shading in brown; and many altitudes are given along roads and at other principal points. Copies of the map may be obtained, through any bookseller, from the Ordnance Survey Office, Southampton.



Digitized by Google

HERE AND THERE.

HIS Highness the Maharajah of Gwalior has just ordered a Turner-Miesse steam car.

MOTOR fire engines are about to be adopted, in place of the usual horse-drawn vehicles, by the Fire Brigade of Dortmund, Germany.

ON this page we give an illustration of the 30-h.p. six-cylinder Napier car, recently delivered by Messrs. S. F. Edge, Limited, to H.R.H. the Duke of Fife. Amongst other recent customers to whom Napier cars have been delivered are the Right Hon. Lord Churchill, the Right Hon. Lord Farquhar, Countess de Grey, and the Countess Gosford. The *chassis* has an extended wheel base. The body, which was built by Messrs. Mulliner, Northampton, has been specially designed, embodying suggestions made by the Duke himself. In type it may be described as a Coupè Limousine with a very roomy interior. The accommodation provides for three people on the rear seat in the usual position; an additional seat is also arranged immediately behind each door, and having a very neat back rest. These seats are ingeniously made to completely fold up and to hinge against the sides of the body in such a manner as to be entirely out of the way when not in use. The upholstery throughout is a special shade of dark green morocco. The roof, both the interior and that over the driver, is panelled with polished mahogany. An electric lamp is fitted in the roof, with a neatly designed switch which can be easily reached by the passengers. The windows in the door slide down, the side windows and those at the back of the driver hinge open, and whether open or shut are held by fittings which prevent any rattle. The extension of the roof above the driver's seat is connected to the dashboard by hollow steel pillars, and over the dashboard itself is fitted a glass wind shield, for the protection of the driver and passenger, for whom a comfortable seat is provided. The scheme of the painting is a very dark green ground, relieved with fine lines of red, and the mouldings being black, the combination giving the whole carriage a very pleasing and harmonious appearance.

The Duke of Fife's Six-Cylinder Napier Car.

THE Central Motor-Car Company, Limited, has been registered with a capital of £10,000 to acquire the business of agents for and dealers in motors, motor-cars, and vehicles carried on by Mr. A. Blakiston, at 117 and 119, Long Acre, W.C., as the American Motor-Car Agency and Central Motor-Car Emporium. The registered office is at 18, Billiter Street, E.C.

ONE of the Avon 4½-h.p. "Trimobiles" with van body is being experimented with by the G.P.O. authorities.

SIR OLIVER LODGE, F.R.S., will read a paper on "Ignition as Applied to Internal Combustion Engines" at a meeting of the Cycle Engineers' Institute on Monday next.

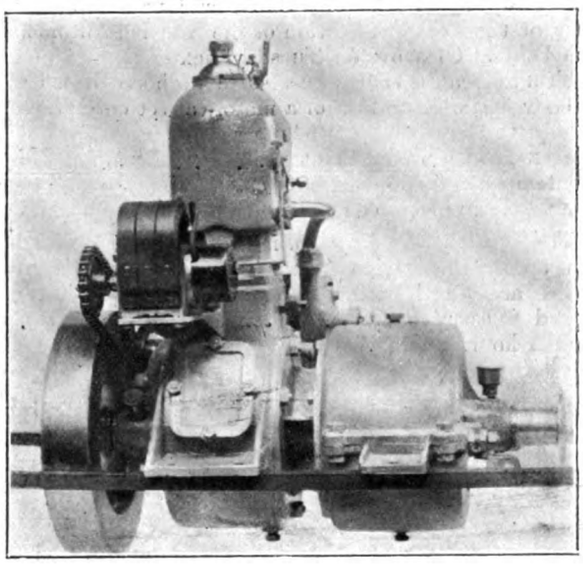
IN Liverpool 306 motor-cars and 321 motor-cycles have been registered during the present year. Seven hundred and twenty-two drivers have been licensed.

SIR MATTHEW ARTHUR, BART., will preside at the annual dinner of the Western Section of the Scottish Automobile Club to be held at Glasgow on Tuesday next.

THE tonneau is the newest style in horse-drawn carriages. The body is similar to that of a motor-car set on carriage wheels, and built to be drawn by two horses.

THE Health Department of Queens Borough, New York, is contemplating adopting automobile ambulances to convey persons suffering from contagious diseases to the hospitals.

THE construction of petrol motor-vans and lorries has been taken up by the Albion Motor-Car Company, Glasgow. The vehicles are fitted with an Albion 16-h.p. motor, and are designed to carry loads of one ton at speeds up to seventeen miles per hour.



ONE of the largest motor garages in New Zealand is that of Messrs. Oates, Lowry and Co., Manchester Street, Christchurch. It is a three-storey building, 70 feet wide, 150 feet deep, and in equipment compares favourably with similar establishments in this country.

MESSRS. DEAN AND BURDEN BROS., LTD., Salisbury, recently fitted one of their 6-h.p. double-cylinder engines to the launch "Maya," belonging to Mr. J. E. Matthews. The first run of the boat was from Chiswick down the Thames to Hole Haven, a distance of fifty-eight miles, which was covered in 5½ hours.

THE British Almanac for 1905 has reached the eighteenth year of issue, and contains a mass of meteorological, official, and general information not so readily accessible elsewhere. One interesting section is that relating to motoring matters, where is a succinct account of the law relating to automobiles, the Gordon Bennett race results, the registration letters for the United Kingdom, and a useful page on "how a motor works," which is sufficiently clear to prove of interest and use to the general public. Among annual works of reference the British Almanac published by Messrs. Charles Letts and Company has a high place.

Digitized by Google

MESSRS. J. W. BROOKE AND COMPANY, LIMITED, have lately introduced a 4-h.p. single-cylinder petrol engine combined with reversing gear, of which an illustration is given herewith. The motor has been specially designed and constructed for motor-boat work, and can be adapted to use either petrol or paraffin. The manipulation of the reversing gear is particularly easy, the three positions, forward, reverse, and neutral, being obtained

with but a slight effort. The ignition is by high tension magneto and the pump is self-contained with the engine. The valves, as will be noticed, are mechanically operated. The actual power is 4½-h.p. at 900 revolutions per minute. They are supplying a small boat fitted with the new engine; it is 15 ft. long by 4 ft. 6 in. beam, clinker-built of spruce with mahogany top strake.

THE next annual meeting of the British Medical Association will be held at Leicester in July next, and a display of motor-cars for medical men will probably be arranged.

AMONG the steam-wagons of the Colonial type recently completed by the Lancashire Steam Motor Co., Limited, was one for Messrs. Wood, Williams and Co., Capetown, and one for the municipal authorities of Greenpoint and Seapoint, South Africa.

FROM Cassell and Company, Limited, comes a copy of Letts' Office Diary and Almanack for 1905, in which, in addition to the usual paper for notes, is a great deal of useful information, making the volume a companionable book for the office desk.

REGRET will be general among those interested in the adoption of the motor-'bus for passenger service in London at the destruction by fire at the garage in Kilburn of some of the motor vehicles which have been plying between the Marble Arch and Kilburn.

SOME city officials of Rotorua (New Zealand), recently went on a tour of inspection by motor-car over a distance of forty-two miles of road over which no automobile had previously journeyed, effecting a saving of time which surprised local people.

ATTEMPTS are being made to secure the application of the ten miles per hour speed limit to motor-cars on the Kilmarnock Road at Giffnock, N.B.

TO their library of Useful Stories Messrs. George Newnes, Limited, have just added the Story of British Trade and Industry, in which Mr. James Burnley sketches the salient stages of our commercial development. He deals with facts of the past and wisely avoids surmises with regard to the future. The reference to motor vehicles, which includes Murdock and Symington, should also have recognised Hancock; but the purpose of the volume is very comprehensive for so small a book; hence only an incidental mention of the subject. The work is well done and every page lucidly written.

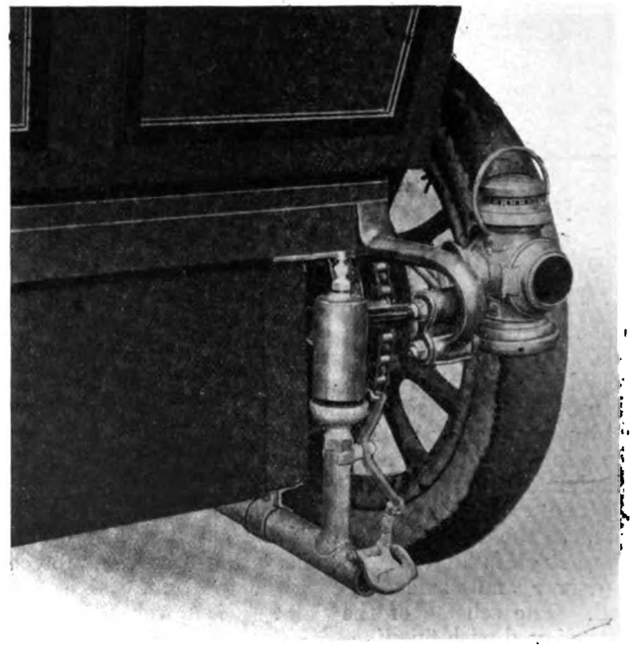
A SERVICE of motor-'buses has been established in Auckland, N.Z., by the Howick Motor-'bus Company.

THE HON. T. A. BRASSEY has a "Star" car, having been determined to possess a motor-car of English make.

THE British Mission to Kabul has left Peshawur for Afghanistan, taking several presents from the Indian Government, including a motor-car for the Ameer.

MESSRS. F. T. BURGESS AND COMPANY have opened a motor garage at Canterbury Terrace, Maida Vale. It has an inspection pit and facilities for all kinds of motor-car repairs.

A STEAM motor dust-collecting and street-watering wagon has just been put in service by the municipal authorities of Paris. It is of 35-h.p., and was built by Messrs. De Dion Bouton and Company.



IN connection with the "Building News" Designing Club plans have just been invited for a doctor's house in the suburbs, one condition being that a motor-house for a motor-car should be provided at the bottom of the garden.

MESSRS. DENNIS BROS., LIMITED, are prepared to hire their one-ton motor-vans to business firms for a nominal charge, so that intending users may compare the cost of mechanical transport with that when horse-drawn vehicles are used.

THE CENTRAL MOTOR CO. have opened a motor garage and works at 82, Town Hall Square, Bolton, with Mr. A. Kirk as manager. Repairs of all kinds will be undertaken and driving taught on the company's cars, or on those belonging to customers.

MESSRS. EASON AND SON, LIMITED, of Dublin, send their Cabinet Scribling Diary for 1905, with double index for rapid reference. The firm's address books and time-saving indexed publications are well known, and their diaries are well up to their reputation.

A NEW alarm for use on motor-cars has been introduced by the Motor Patent Appliances Company in the form of a whistle attached to the rear of the car and operated from the dashboard by a hand or foot lever. Different sizes of whistle alarms are provided for cars of various sizes and powers, and the device is fixed, with a lever and shutter arrangement, to a short

length of tubing attached to the exhaust pipe leading from the silencer. When the alarm is sounded the shutter is closed, thus directing the exhaust through the whistle. The location of the device is shown in the accompanying illustration, and the clear and strong alarm thus afforded will also keep dogs from the car as well as warn pedestrians and others as to the presence of an automobile.

Digitized by Google

THE STANLEY SHOW.

(*Concluded from page* 808.)

Messrs. J. LACOSTE AND COMPANY made a good display of accumulators, coils, and contact breakers, charging boards, and other electrical accessories for automobiles. A new type of accumulator was submitted for public criticism, in which each element is made up of small positive plates enclosed at each end by groups of negative plates, which plates are respectively connected, at the top by lugs in the ordinary way, and at the bottom by brackets electrically soldered to each plate. This bracket, besides keeping them the necessary distance apart from each other, makes a very solid block of each group. The available active surface has been greatly increased, while rigidity has also been improved.

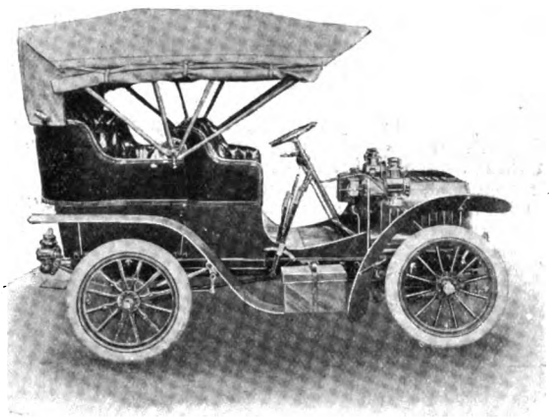


Fig 1.—The Crypto 8-h.p. with Cape cart hood. (*See last issue*).

Several charging boards, for charging small accumulators, were on view, and also a high-tension switch for use with high-tension coil and accumulators, and magneto ignition, for running on either of these without stopping the engine.

Messrs. F. REDDAWAY AND COMPANY, LIMITED, whose association with motor tyres is a matter of importance to owners of cars, have made an advance by the combination of endless wires and beaded edges in their Camel motor and motor-cycle tyres. In the construction, some of the layers of canvas are passed around the wires, while the others form the bead, the strain thus being equally divided, with resultant strength to the beads. A tubeless tyre on a similarly effective principle was also shown on this stand, in which the rubber-lined inner faces of the tyre near the bead were compressed against an inner metal ring by a divided rim. The two portions of the latter are connected by means of bolts and nuts, and as soon as these are undone, the tyre can be lifted off by hand.

THE recent expiry of the Welch and Bartlett patents directed unusual attention to the exhibit of the DUNLOP COMPANY, who remind the public that although the Welch and Bartlett patents have expired, the Doughty patent, under which Dunlop tyres have been made for the last two seasons, is still in force. The Dunlop motor-cycle tyres have been exceptionally successful during the past season, and the policy of providing tyres of larger diameter than had formerly been in vogue upon motor-bicycles and tri-cars has proved acceptable to users. Similar success has attended the improved Dunlop tyres for motor-cars with non-slipping treads. Not the least interesting part of this exhibit was the company's line of repair outfits, ranging from the wooden box, filled with materials for the repair of motor-car tyres, down through the compact outfit for motor-cycle tyres, to the Midget outfit for repairing cycle tyres.

The DUNLOP RUBBER COMPANY shared in this exhibit, their display taking the form of a varied assortment of waterproof garments suitable for motoring, as well as such luxuries as air cushions, collapsible

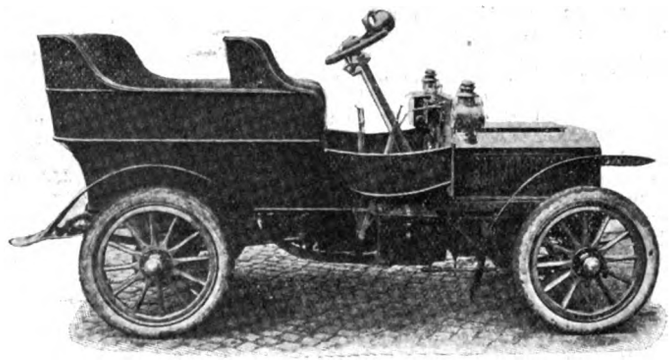

Fig. 2.—The Humber 8-10-h.p. four-cylinder Car. (*See last issue*).

buckets, motor-car covers, spare tube bags, and a new waterproof bag for containing spare tyre covers.

The "Imperial" compressed rubber and fabric non-skidding treads were on the stand of the IMPERIAL TYRE AND RUBBER COMPANY, LIMITED, whose facilities for the repair of motor-tyres of all kinds should be familiar to all motorists.

At PRICE'S PATENT CANDLE COMPANY'S stand a "Guide to the Selection of Lubricants for Motor-cars" proved a popular souvenir of the Exhibition. This sets forth the qualities and properties of Belmoline solidified oil for gear cases, Cirogene for chains, and other specialities for various parts of the automobile.

The HALLE SPRING WHEEL SYNDICATE, LIMITED, were represented by a patent spring wheel and a working model illustrative of the principle of their invention. This gains its utility and its distinctive character from the fact that a horizontal spring has been adopted in such a way that side play is a mechanical impossibility. The drive, although yielding to any sudden pressure of the engine, has no effect on the resilient springs. The appliance can be employed on cars of any power.

Messrs. S. SMITH AND SON, LIMITED, had their usual comprehensive display of motor watches, speed indicators, and similar articles for fixing to cars, and proving of convenience to motorists. Accuracy of adjustment is a feature of this firm's well-reputed productions.

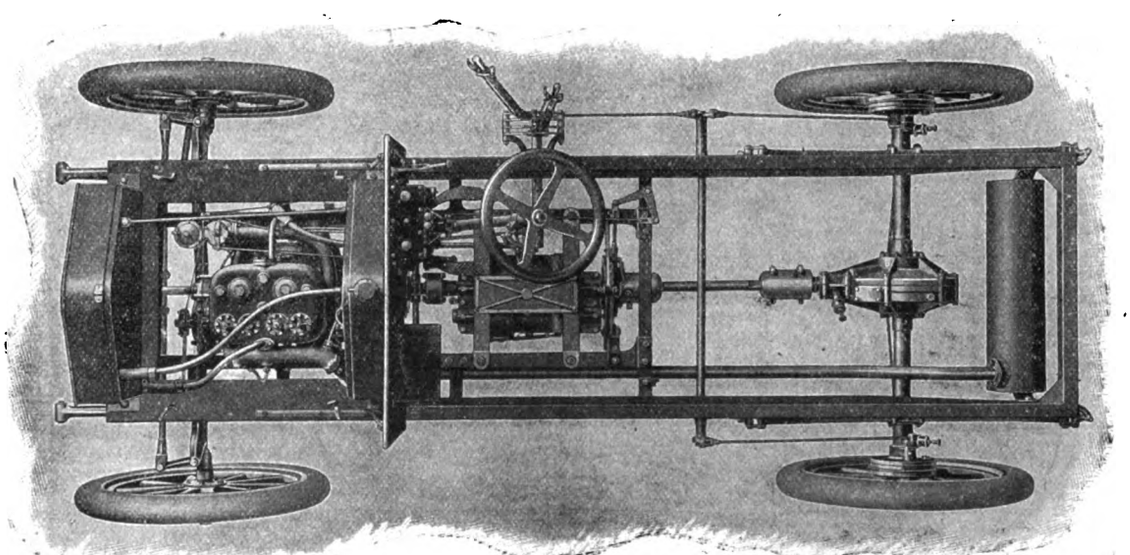

Fig. 3.—Plan View of the "Heron" 12-h.p. Double-cylinder Car.—A description of this vehicle was published in the *Journal* of September 3rd last.

Digitized by Google

The STERN SONNEBORN OIL COMPANY, LIMITED, have long been exhibitors at Agricultural Hall shows, and their oils and lubricants are well-known to practical motorists. Autosternol oil A is a pure hydro-carbon oil, non-corrosive, free from impurities, and specially recommended for air-cooled cylinders. Others are prepared with a view to use of bearings, axles, gear boxes, and other parts. The Fram chain lubricant must not be overlooked in a reference, however brief, to this stand, the preparation reducing wear and tear and noise to a minimum, preserving the chains, and preventing friction.

A solid tyre for light and heavy motor-cars, giving a resiliency similar to that of the pneumatic, was a feature of the stand of Messrs. J. E. HOPKINSON AND COMPANY, LIMITED. Twin non-slipping treads are a special feature in the construction of this tyre.

The "Pickering" wheel was exhibited by the HIGHGATE IMPLEMENT WORKS, LIMITED, of Tweedmouth, Berwick-on-Tweed. This is designed for use on motor-cars and wagons.

The REX MOTOR MANUFACTURING CO. made a big display of their 1905 type of 3¼-h.p. Rex motor-bicycle, which has been improved in several parts. The engine, which is bolted into a special cradle, and does not form part of the frame, has a cylinder 82 mm. diameter by 82 mm. stroke, mechanically-operated inlet valve, a new pattern of silencer, double air draught to both valves, and spray carburettor. The valves are placed on the left side of the engine, both chambers being separated from the engine and each other by air passages. The new silencer is a great improvement on the baffle plates hitherto used. The exhaust is discharged into a box, shaped like a beehive, which contains a number of pipes drilled with small holes. The gases pass from the beehive into another chamber, situated underneath the valve seatings, and are finally discharged downwards into the air. It is claimed that, there is an absence of back pressure, and that the noise is reduced to a minimum. The Longuemare carburettor is enclosed in the bottom of the tank. It is, however, easily accessible. The frame has been lowered, 4in. and 26-in. wheels are used. Two brakes are fitted, the front one being a new design, taking its fulcrum from a bridge between the extension and the forks. The rear brake is actuated by the left foot. The weight of the machine has been considerably reduced, being now 125 lbs.

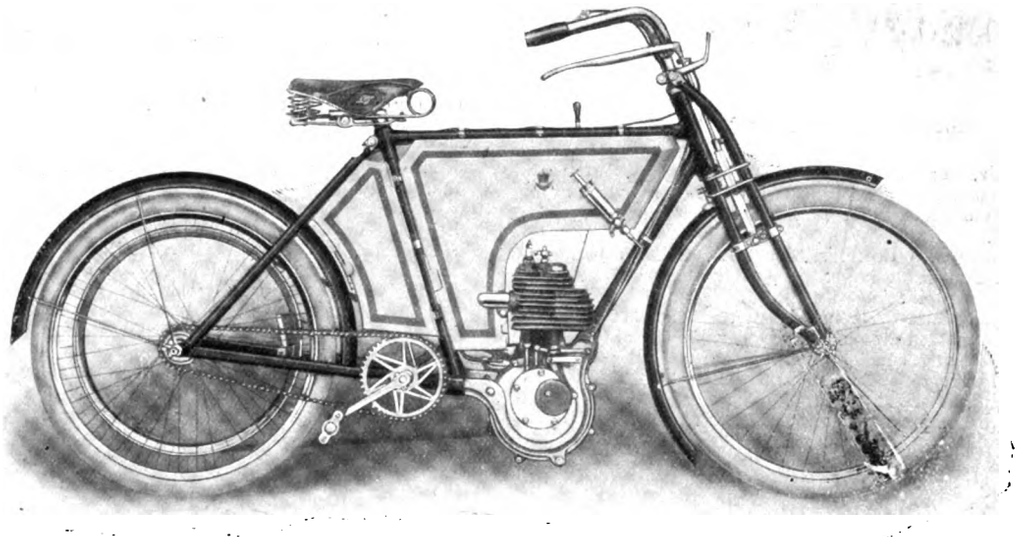

Fig. 4.—The 1905 3¼-h.p. Rex Motor-Bicycle.

The well-known "H. F." vulcaniser was brought again to public notice by Messrs. HARVEY FROST AND COMPANY, LIMITED. This has already been illustrated and described in our columns, and it remains but to say that the firm have now brought out the "Car" vulcaniser, especially designed with a view to overcoming tyre difficulties on the road, or in cases of urgent need. It is of handy shape, easily handled, and only 20 lbs. in weight, embodying the same principle of vulcanising as has been adopted for some time in the "H. F." vulcaniser. The "Car" vulcaniser is made to fit in a neat little box to affix to the vehicle.

Lamps and horns were the central objects of motoring interest on the stand of Messrs. STEINER AND COMPANY. A treble-turn horn producing a very deep note was worthy attention, and the firm's novelties in tail lamps included several well-designed goods.

Rubber goods of all kinds were exhibited by Messrs. W. AND A. BATES, LIMITED, of Leicester, whose facilities for production are being recognised throughout the trade.

The Sawyer non-skid band is a leather covering for the rubber tyre, provided with a tread in which steel studs are inserted. Messrs. SAWYER AND CO. claim that punctures and skidding are alike prevented, while the reliancy of the tyre being unaffected the device is as serviceable on light as on heavy cars.

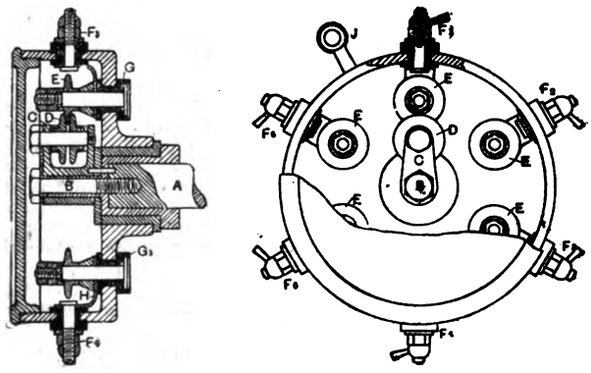
The Universal silencer was shown by SHARPE'S "UNIVERSAL" PATENTS CO. The main features of this efficient silencer have already been described in our columns; suffice it now to say that for the coming season an important improvement has been introduced. The exhaust gas passages on the outside of the bulbs have been much reduced in length, being now cut through thin belts cast on the extreme circumference of the bulbs, thus reducing friction and increasing the freedom of the exhaust gases on the passage to the exit.

M. ANDRE A. GODIN attracted attention to his stand by an exhibit of the Hydra sparking plugs, in which simplicity of construction is combined with efficiency in operation. He also showed the well-known Dinin accumulators for all classes of motor vehicles. In the constitution of the electrodes for these accumulators provision has been made for the lengthened retention of the charge, an advantage when employed in connection with the electrical ignition in motor cylinders. For illuminating both the inside and exterior of vehicles two principal types of batteries are provided, type 11 having a capacity for one interior lamp of 8-candle-power during twenty hours, and two exterior ones of 5-candle-power during fifteen hours. In view of the difficulties that have arisen in connection with the lighting of cars under the Motor Car Act, special interest attaches to the Dinin system of transforming ordinary carriage lamps into electric ones. There was also shown by M. Godin a useful adapter for re-charging accumulators. This is applicable wherever it is possible to obtain a supply of continuous current from an electric lighting installation.

In view of the great development which is taking place in tri-cars, the exhibit of Messrs. OPPERMANN AND SONS, Clerkenwell, was of more than passing interest. It consisted of a combined clutch and three-speed gear, in which the three pairs of wheels are always in mesh. The sliding shaft is provided with three equi-distant feathers, which fit into corresponding slots in the pinions running idle on the shaft. The gear is very compact, and although it has only been on the market a short time has already met with a large adoption. A two-speed gear on similar lines for motor-cycles is also being introduced.

In the way of motor-car and cycle accessories the visitor to the show found an extensive range at the stand of Messrs. BROWN BROTHERS, LTD. These included an excellently constructed jack, the Duco non-slipping band, and a new Duco side lamp. In addition there was a complete range of E.I.C. ignition specialities, for which this firm are special agents. Various types of sparking plugs, voltmeters, and other electrical parts were also shown. Two novelties were the Bronko free-wheel hub and New Departure coaster hub for motor-bicycles. The new Brown free engine clutch for tri-cars was also worthy of notice, while finally we may mention that Messrs. Brown Brothers have arranged with the makers of the Longuemare carburettor to carry an exceptionally large stock of these articles.

The BRITISH-AMERICAN CO. exhibited the Halliday light folding hoods for motor-cars, which provide an interchangeable top for motor-cars of exceptionally neat appearance. The uprights attached to the body of the



Digitized by Google

car are so arranged that there is no obstruction to free ingress and egress for the vehicle, while curtains at the sides and rear can be drawn to protect passengers from wind and dust. Effective in operation and easily collapsible when desired, although perfectly rigid when in use, the Halliday top should become a popular feature in the British trade. The same company also showed a good type of motor-car jack, in which the extension is effected by a very easy movement, the device being collapsed in stages, which prevent the jerking associated with those jacks that are suddenly reduced to their normal position. Strong in construction and simple to work, the British-American Co.'s jack will be found serviceable in all circumstances.

Messrs. WALSH, NICHOLLS AND Co. had a display of radiators for tri-cars, as well as those specially designed for cars of a larger make. To assist those who are now interesting themselves in the development of the tri-car the firm has made a special study of tanks and radiators for these little cars, with the result that several good types were to be seen on their stand.

An interesting display was made by the BOWEN AND ODERY MANUFACTURING Co., of Greenwich, whose ignition accumulators for cars and cycles attracted much attention from expert visitors. The M.I.E. accumulators, which constitute a leading line of manufacture with the firm, are specially intended to withstand vibration and rough usage. In these the plates are separated by pierced corrugated celluloid, and are arranged so that internal short-circuits are practically impossible. Very heavy connection lugs are provided, the chance of breakage being thus materially reduced. Another type made by the Bowen and Odery Co. is a 4-volt battery sealed with a special composition to prevent the creeping of the acid and surface leakage. The terminals being cased in ebonite are absolutely acid-proof. Altogether the accumulators introduced by this firm have been carefully designed and constructed, and motorists should not neglect to see these good productions. Small charging dynamos, sparking plugs, voltmeters, test lamps, etc., were also shown, and attention drawn to the facilities the firm have at Greenwich for accumulator and coil repairs.

A good display was made by the ASTON MOTOR ACCESSORIES Co., LTD., of Birmingham, whose specialities include the Amac contact maker, which works effectively and silently. It is complete in itself, and ensures

Figs. 5 and 6.—Sections of "Amac" Contact-maker.

a perfect contact, while the absence of flimsy parts secures the longevity of the device. To meet the demand for a strong switch in no way affected by vibration the Amac switch has been introduced, a notable feature being that the contact piece does not revolve, but gives a rubbing contact. The current has not to pass through any bearings. Reliable sparking plugs and terminal clips are also made by the Aston Motor Accessories Co., Ltd., whose goods are characterised by excellence of workmanship as well as design. The A.V. patent radiators and radiator tubing are other leading specialities. In the latter the actual contact between the gills and the tube is claimed to be perfect owing to the design, and the special method of soldering. The cooling surface is more than 150 square inches per lineal foot, and in the Glasgow to London trial of the present year a car fitted with this tubing made the highest possible marks for a non-stop run, being awarded a gold medal.

The Palmer cord motor-tyre was exhibited by the PALMER TYRE, LTD. The features of this motor-car tyre, which has proved itself to be a strong and reliable speciality of the makers, have been often referred to in our columns. One great feature is the uniformity of tension of threads attained by the special principle of manufacture, all the threads of canvas or webbing being arranged so that the strains are direct. An important point in connection with the tyre is the way in which the special plan of construction lends itself to the effectual repair of bad cuts and gashes, which may have penetrated both layers of cord. The method adopted is to remove the damaged cords, and insert in their place an equal number of new cords, which are secured to the anchorage of the bead in precisely the same manner as the original cords. The rubber tread is then made good and vulcanised, the repaired portion being equally as strong as the original tyre and the section of the tyre, and consequently its resiliency, remains unaltered. This method marks a distinct advance on the practice hitherto followed for repairing canvas-lined tyres, and will be appreciated by those to whom economy is a consideration.

In the section for oils, etc., appeared Messrs. WOODGATES BROS. with automobile tyre repair outfits, and a duplex patch indicated as "The patch that won't come off." They also had a varied collection of oils for the various component parts of the car.

Messrs. SALSBURY AND SON, LIMITED, the spelling of whose name should be noted by motorists, had their familiar range of Salsbury

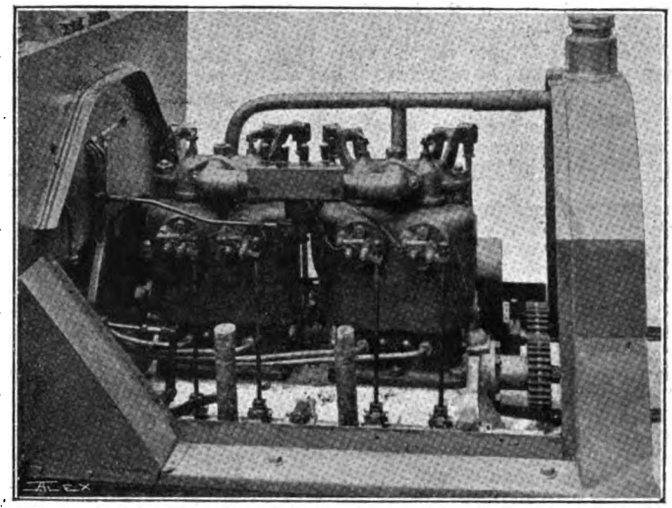


Fig. 7.—View of Engine of new Star 10-h.p. four-cylinder Car. (*See last issue*).

lamps, Salsbury-Dietz Orient lamps, Dietz tail lamps, etc. A garage petrol funnel, and the Duplex folding pail, were a couple of useful little novelties that added to the interest of their stand.

A large display of the Gaulois tyres for motor-cars was shown by Messrs. GAUTHIER AND COMPANY, whose exhibits also included Malicet and Blin's steering gears and axles, Longuemare carburettors, of the 1905 type, Dubrulle lubricators, radiators, pumps and platinum metal for body building. We hope to refer to the Gaulois tyre on another occasion.

Messrs. LAKE AND ELLIOT had a collection of motor accessories, including the Millenium motor packs, one type of which has been specially designed with a long handle to obviate the necessity of crawling beneath the car.

In King Edward's Hall the Reilloc resilient solid tyres were exhibited by the REILLOC TYRE COMPANY. This is the invention of Mr. Arthur Collier, whose idea has been to produce a solid tyre in which a resilient rubber could be employed at a cheaper rate than has hitherto been regarded probable. The Reilloc tyre is much more resilient than the ordinary solid, as the rubber, instead of being held in an upturned rim, is held to the wheel by fabric of the finest Egyptian cotton embedded and vulcanised into the rubber, much as a pneumatic cover is held. As then there is no waste of rubber inside the rim, and all of it is used for cushioning the car, a tyre is produced which has more the appearance of a pneumatic than a solid tyre. The fastening, which makes the tyre detachable, enables

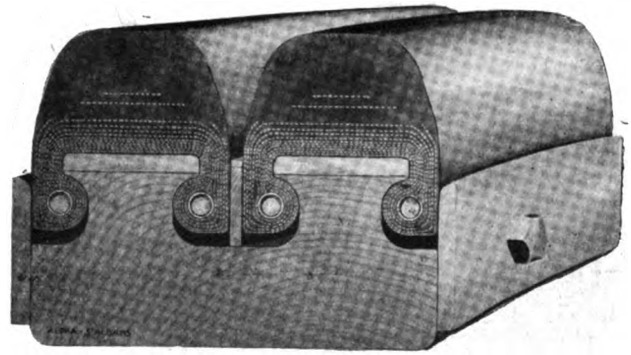

Fig. 8.—The Reilloc "Dual" Tyre.

any local wheelwright to effect the repair, in case of a damaged wheel, without the expense and delay occasioned where electrically welded wires are used and the wheel has to be sent to the tyre firms for repairs. A thick steel wire, having the ends tapped wit hleft and right threads, is united by a strong barrel nut about 3 ins. long, which enables the tyre to be pulled tightly down over the wheel, and is encased by a spiral wire of slightly larger dimensions, allowing the central wire to pass freely. In the cases of very heavy weights these tyres are run as duals, as shown in the accompanying illustration.

Digitized by Google

A large selection of covers, inner tubes, etc., for motor tyres, was on the stand of Messrs. CAPON, HEATON AND COMPANY, LIMITED, whose display of general india-rubber goods was of a high-class character. Michelin tyres—made famous in the 1904 Gordon Bennett and other classic races—constituted a good display. The Clipper Continental motor tyres were prominent on the stand of the CONTINENTAL CAOUTCHOUC AND GUTTA-PERCHA COMPANY. The NORTH BRITISH RUBBER COMPANY, LIMITED, had a large selection of their Clincher motor tyres, and the CLIPPER TYRE COMPANY, LIMITED, showed the Clipper-Continental tyres, and the Reflex-Clipper motor-bicycle tyres. Messrs. MACINTOSH AND COMPANY, LIMITED, of Manchester, had a large selection of their motor tyres, and repair patches, etc., as well as a Macintosh motor-cycle tyre.

Among other exhibits of interest were the "Chicago Rawhide" V-shaped belts for motor-cycles, cut at an angle of 35 deg.; the "Fast-nut" washer for holding square or hexagonal nuts perfectly tight; and the "Lincona" motor-cycle belt, and the Lincona dressing, which is regarded by many riders as an indispensable equipment of the tool bag. Motor castings were shown by the MOTOR CASTINGS COMPANY, LIMITED; and the Gripwell brake, for motor-bicycles, by Messrs. WASS AND COCKS, LIMITED. Messrs. ELLIOTT, HALLAS AND SONS, LIMITED, of Huddersfield, had a good show of motor-cycle belts, motor-tyre gaiters, and the like, as well as their non-skidding device. Motor clothing of good design was to be found on the stand of M. VOLLANT, who made a creditable first appearance at these shows. Steel balls of a really remarkable degree of accuracy formed the exhibit of the Hoffman Company; a selection of bifurcated rivets of all sizes, and automatic self-feeding rivet-setting machines was exhibited by the company bearing the name of these useful goods; the "Acetyphote" and Silver King lamps were on the stand of Messrs. JOSEPH LUCAS, LIMITED, who also drew attention to the protector for the flexible tubing of foot pumps; and Messrs. W. CANNING AND COMPANY had a selection of transformers and regulating apparatus, for charging automobile accumulators.

A good range of automobile requisites was shown by Messrs. LEWIS'S, of Liverpool, whose advent to the trade has considerably enlarged the motorist's choice of clothing. A special feature is the Laveroc apron coat, comprising a combined apron and overcoat. Russian foalskin furs are utilised in some garments of particularly good style, and a high-class waterproof tweed in motor coats, used either when walking or motoring. Car covers, mats and matting, overalls, gloves, gauntlets, goggles—including a folding variety which can be carried in the waistcoat pocket—lamps, horns, jacks, petrol and water funnels were included in a very comprehensive display.

Aluminium rectifiers for changing any class of accumulators direct from alternating mains were on the stand of Messrs. STEWART, LIVETT AND CO. These work on any voltage, and there being no moving parts, require no attention. They are made in four sizes, from ½ to 6 amperes, and will enable many motorists to charge their accumulators at home.

The COUNTY CHEMICAL CO., LTD., of Birmingham, introduced their G.B. vulcanisers designed to secure uniformity in temperature and to conduct the heat to the vulcanising plate as effectually as when superheated steam is employed. Three types are being placed on the market. In one the temperature is obtained by the employment of a preheated iron block, and the device can be carried on the car with a view to effecting minor repairs on the roadside. Another pattern is shown in Fig. 9,

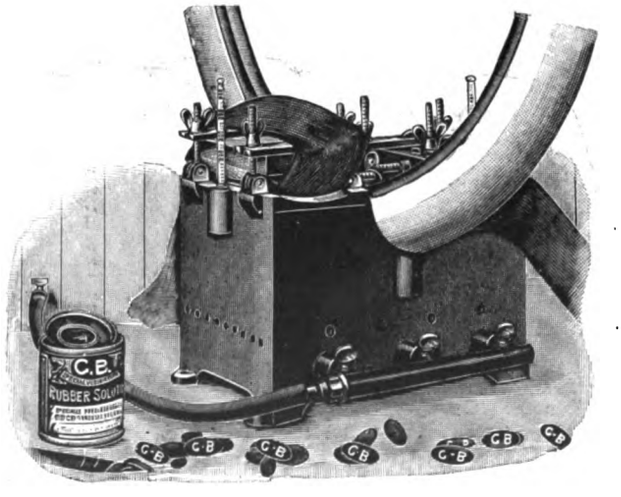

Fig. 9.—The "GB" Tyre Vulcaniser.

which is designed to deal with air tubes and outer covers simultaneously. Provision is made for valve seatings to be vulcanised on with valves in position. The interior of the apparatus is constructed in compartments, so that when desirable only a section of the vulcaniser need be heated. Vulcanising materials are also supplied by the County Chemical Co., Ltd., whose specialities include lubricating oils, repair outfits, and a full range of similar goods.

Mr. G. GOLDSCHMIDT is the sole concessionaire for the United Kingdom for the Jupiter headlight, and made a good show of such specialities, one of which is shown in the accompanying illustration. The headlight is fitted with a double reflecto throwing the light for 200 yards ahead. It is easily and quickly opened and charged, a new means of undoing and fixing the carbide container from the top having been devised. The lamp is made in four sizes, and provides an efficient as well as a convenient headlight. Mr. Goldschmidt also showed the Jupiter light with separate generator, and the "Victoria" acetylene motor-cycle lamp

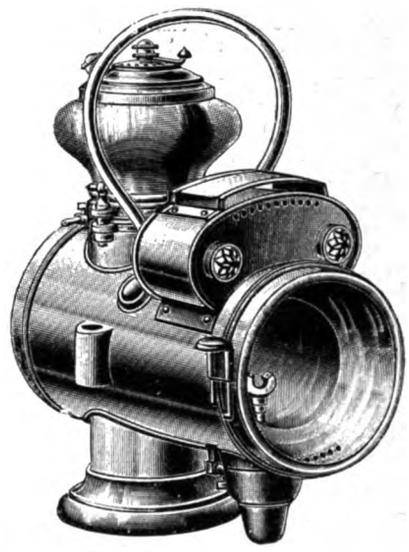

Fig. 10.—The "Jupiter" Acetylene Headlight.

this latter being a strong type of lamp specially designed to withstand the vibration attendant on such forms of automobiles. New petroleum headlights, sidelamps and tail lamps were also on the stand, as well as the Zanardini lamp previously described in these columns. Horns, funnels, sparking plugs, oilers, pumps, etc., were included in the display, and the selection of goggles was complete and comprehensive, including the Merz patent capsule goggle, which affords a good protection against dust, draught, etc. The particular make of the capsule edges is claimed to secure a greatly improved vision, while the unpleasant pressure on the face which detracts from the use of many other goggles is unknown in these. They are certainly worthy the consideration of motorists who do much riding.

The Prested safety lamp, exhibited by the PRESTED MINERS' GAS INDICATING ELECTRIC LAMP COMPANY, LIMITED, is well adapted for use in motor sheds, garages, and places where petrol is stored. The light is thoroughly safe and will burn continuously for ten hours without the necessity of re-charging. The company also showed their battery for motor-cars. The cases of these are of teak, rendered acid proof and non-conducting by a special process; so that both risks of breakage and leakage are obviated. The plates are held in position by a special non-conducting composition which is introduced in a melted state, and when set, holds the plates fixed and immovable. These batteries are fitted with acid level indicators, nickel-plated terminals, and strong straps, and being well finished and polished present an excellent appearance. The composition of the plates is the secret of the company. The negative plate is a pure lead sponge and the positive a very rich-coloured peroxide. The good colour of both negative and positive plate, indicating a maximum of chemical electrical efficiency, is maintained with great constancy, a fact which is encouraging the firm to offer a series of prizes to users who keep a record of the behaviour of the batteries on their cars.

THE Otto-Bennett Company have made arrangements whereby purchasers of their Otto or See non-skids can be fitted with either Dunlop or Michelin tyres at reduced prices.

IT has been variously reported that the Bowden Mechanism Patent (No. 25325 of 1896), or the Bowden Brake Patent (No 14402 of 1897), has been revoked on a petition before Mr. Justice Farwell on the 16th ult. The E. M. Bowden's Patents Syndicate, Limited, ask us to mention that neither statement is true. The case referred to affected only the mechanism patent, and the judge held that unless the Syndicate appealed or made amendment of the patent, it would be revoked in fourteen days. As one or other course will certainly be taken, the patent rights remain in force.

CORRESPONDENCE.

MOTOR-CAR REPAIRS.

To the Editor of *The Motor-Car Journal*.

Sir,—Referring to Mr. L. P. Darby's letter in the last issue of the *Journal*, so new a business as the repair of motor-cars cannot but have many annoying and disagreeable features. There are many conscientious and skilled repairers, yet there are many incompetent ones in the trade, and it is the latter class that are productive of a great deal of the prevailing dissatisfaction. They make mistakes and they do poor and slipshod work. Thoroughness is not one of their cardinal doctrines. They sometimes effect a repair without removing the cause, and in a short time there is a recurrence of the trouble and the work has to be done over again. The owner of the car is annoyed, and believes that the repairer is incompetent. This may well lead to a withdrawal of patronage, and ultimately to a sweeping condemnation of all repair shops. Sometimes this is merited, and sometimes not. The motorist should, however, bear in mind, first, that the automobile is new, comparatively, and therefore more difficult to understand than it will be a few years later; second, that all intricate mechanisms are liable to develop puzzling diseases and to give trouble to even the most expert workmen. The quick-witted repairer, who locates the seat of the trouble and puts it to rights in five minutes, performs wonders: and he would be dull-witted to charge only for five minutes' work. Similarly a baffling "panne" that defies detection for hours, but is finally detected and made right with a turn of a screwdriver, is worth all the time spent on it. But the motorist does not always view it in this light, and fumes at what he terms a gross overcharge. In the motor repair business it is the employer's interest to have only good men in his shop, and he must eventually either train or educate the raw material he possesses or make it worth while for more expert mechanics to enter his employment. Then, and then only, will the loud and insistent complaints we now hear on every side cease to be made.—Yours truly,

C. A. Ashton.

BRITISH AND FOREIGN CARS.

To the Editor of *The Motor-Car Journal*.

Sir,—Referring to the discussion taking place in the *Journal* on this subject, I think there is no question that the statement put forward by Mr. Jarrott has been more than verified by the latest published figures as to the English trade in motor-cars up to the end of October. Mr. Jarrott was undoubtedly right, England is losing ground and that rapidly. The following figures bear this out:—

Number of cars and motor-cycles imported for the ten months ending October, 5,811.

Total value of cars, motor-cycles, and parts imported, £2,219,912.

The following miserable figures give in comparison what England has exported.

Motor-cycles and motor-cars, 1,137.

Total value of cars, motor-cycles, and parts, £268,466.

I think these figures close the discussion with honours for Mr. Jarrott, although it will certainly be interesting to hear what Mr. Edge and others have to say in answer.—Yours truly,

R. Seton.

PRIMARY CELLS FOR CHARGING ACCUMULATORS.

To the Editor of *The Motor-Car Journal*.

Sir,—Whilst staying at Pietersburg last year I procured second-hand a set of charging batteries for the purpose of recharging the accumulators of my motor-car. Unfortunately the labels had in most cases become detached, leaving only a small portion on one cell, revealing evidently a trade mark of rather gruesome nature in the shape of a skull and cross bones; also a registered number. I have done over 10,000 miles with accumulators charged by these cells alone, and never once been stranded. Unfortunately, on unpacking my box, I discovered two of my cells broken, and am now on the look-out for a new set with which to replenish my accumulators. I should be much obliged if some reader would kindly inform me the name of the manufacturer of these cells or where I can procure them. I have many times been advised to use Boron cells, but do not know whether these are the same.—Yours truly,

C. Crompton.

BELT TRANSMISSION.

To the Editor of *The Motor-Car Journal*.

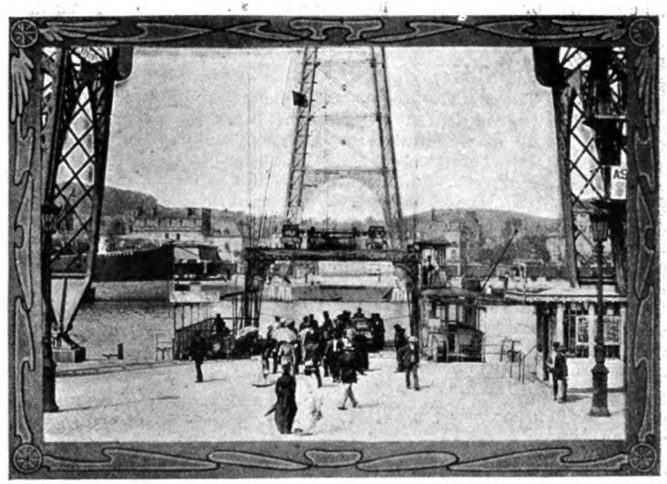
Sir,—As no one has volunteered a reply to "Lancastrian" and "J. B." asking if any weak spots are apparent to experts in the "Dent" car described in your issue of October 15th, I beg to offer my opinion for what it is worth. I may say at the outset that I was rather taken with its striking simplicity, and if well set out and constructed, and a suitable first-class belt used, I think the difficulties of former systems will be overcome. The weakest point I can see is the position of the engine; this, however, could be neutralised by placing the valves in accessible positions, and the commutator on the dash. As regards balance, as the front cone forms the engine flywheel the weight can easily be placed as required. At the rear end, if the belt has the gear-like grip mentioned, I think a loose pulley at the slow end a necessity and a distinct advantage; then in pulling up the belt would brake the car up to the low speed, the brakes would do the rest, the belt would take the loose pulley of the vehicle, move off slowly or quickly as desired, and *vice versa*, giving excellent control in traffic. The back axle, however, is not very clear from the sketches, although the principle is good. The points I have mentioned may probably have occurred to the inventors.—Yours truly,

A Mechanic.

WATER CHARGES.

To the Editor of *The Motor-Car Journal*.

Sir,—I should be glad if you, or any reader of the *Journal*, could enlighten me as to the charge in London, extra above domestic supply, for water where a motor-car is kept? I am being charged one guinea per annum, which I think extortionate and have protested, but without result up to now. I have offered 10s. per annum, which is refused.



They admit the regular charge for a carriage is 8s. per annum, and for each horse the same. I have explained that there is no steam boiler to fill, simply washing occasionally like an ordinary carriage, and there is no logical reason why more than 8s. per annum for water should be charged. By what act, rule or reason is the charge of one guinea made?

If it is on the assumption that every person who keeps a motor-car is worth £10,000 a year, then why do not the revenue authorities charge 150 per cent. more for a licence for a motor-car than a carriage? but they do not.

Is it right that we should submit to this unjust charge?

If there is any way known to yourself, or any of the numerous readers of the *Journal*, how to get a motor-car recognised as a carriage (they charge all vehicles alike except motor-cars) for the purposes of the water rate, I, and no doubt many others, would be thankful for such information, as it is not a personal matter, but must affect many other motorists besides myself.—Yours truly,

London Motorist.

The Floating Bridge Across the Seine at Rouen.

WORK ON ROADS

To the Editor of *The Motor-Car Journal*.

Sir,—Would it not be a good thing if the "powers that be" would take advantage of the present state of employment in the country to straighten and level some of the roads in the country? All users of the roads are familiar with places which are not wide enough for the growing traffic; there must be thousands of such localities, and it would be well if the present time could be used to improve them. I offer this both as a means of helping the unemployed and also the users of the road.—Yours truly,

A. F. 76.

STEAM CARS AND THE BLACKPOOL TRIALS.

To the Editor of *The Motor-Car Journal*.

Sir,—Up to the present no one has come forward and given a reason why steam cars were debarred at the Blackpool trials. This is not satisfactory; a good many would-be motorists are forming their own opinion on the matter to the detriment of the petrol car. In my humble opinion it is not fair to allow a steam car to compete in a short race or a hill climb with petrol cars; a steam car has all its energy stored ready for a short run or climb and can do it well, but afterwards it is not always ready to continue its performance. It is plain a petrol car would not have a chance in a short run. I therefore contend that it is not fair to allow the steam cars to enter on hill climbs or short runs. Allow them to compete on a long run. If the above is the reason why steam cars were not allowed to compete, why does one of the officials not come forward and state the facts? It would be more satisfactory to those interested in petrol cars to have some facts.—Yours truly,

T. E. Henderson.

PANHARD IGNITION.

To the Editor of *The Motor-Car Journal.*

Sir,—On page 810 of the last issue of the *Journal* "H. H. H." writes asking for hints with regard to the adjustment of the magneto ignition on the latest Panhard cars. This is the Eisemann system, and we shall at all times be glad to assist "R. H. H." if he will write to us, or go over the system with him if he is in London and will call. The part requiring the most attention is the hinged steel arm carrying the upper platinum point; both the hinge and the pin of the roller should be oiled occasionally, but a small bicycle oil-can should be used, as the large oil-cans found on cars feed too much oil, which splashes about and gets on to the points and the copper collecting rings, and it is on the latter that the oil gives most trouble; the rings must be kept quite dry and free from oil, and if allowed to get into a dirty state, the carbon brushes which rub on these rings should be soaked in petrol for a short time. As regards the platinum points, there is but little burning of these, but the continual tapping flattens them out after a time, when they should be filed quite flat and adjusted so that when the points are separated by the cam they are not more than 1-32 in. apart, any excessive distance between the points causing more rapid wear and considerable weakening of the spark.—Yours truly,

G. T. Riches and Co.

To the Editor of *The Motor-Car Journal.*

Sir,—In reply to "R. H. H." in your last issue *re* Panhard ignition, I would like to call his attention to these points. 1. Never screw down the Stauffer on the commutator more than ¼ turn per diem. 2. Keep the brushes at as little tension as will make contact; if they are down very hard on the fibre ring they will very soon cut or score it. 3. Wash out the commutator once a week or oftener if convenient. 4. Keep the screws on the coil as light on to the trembler as possible or bad sparking will result between the platinum points. 5. If a series of misfires occur do not fly to the coil and begin screwing up and down, but look first at the commutator and next at the coil.—Yours faithfully.

Charles Storr.

THE LANCHESTER CAR.

To the Editor of *The Motor-Car Journal.*

Sir,—I am pleased to give "Enquirer" my experience of above. I have owned and driven many cars of good make, with two and four cylinders. My latest purchase is a 12-h.p. water cooled Lanchester. I have driven it nearly nine thousand miles without a hitch or adjustment of any kind. My only delays have been to change an igniter and an occasional puncture; the brake and clutch want a little attention, which is easily observed by the position of the lever. This I do at home when required. The car is a wonderful hill climber, and has made several runs of more than one hundred miles on top speed. It can always be started on second without undue strain on the engine or gears. The change speed is certain, simple and noiseless—no grating and risk of missing or running through gears. With regard to "Enquirer's" queries, I will answer them seriatim as follows:—

1. I prefer the Lanchester tiller to the wheel. 2. No experience of air-cooled cars. 3. No, but sufficient. 4. Ditto; both, one engine does more work than the other. 5. Yes 6. Less; no accumulators, coil, wires, switch, &c. 7. Absolutely without an effort. 8. See above; fastest 12-h.p. I have driven.

I am not interested in any motor business, and am more than pleased with my purchase.—Yours truly,

F. W. T.

To the Editor of *The Motor-Car Journal.*

Sir,—I think that I may be able to give "Enquirer" some disinterested advice in regard to the Lanchester car. I have not been myself the owner of any other make of car, but my son has owned two of the usual type, so I know something of both sides. May I answer "Enquirer's" questions *seriatim?* (1) The Lanchester tiller-steering is certainly easier than wheel-steering, and it is absolutely reliable. I can guide my Lanchester with finger and thumb on a rough road. (2) I have driven my car over 16,000 miles air-cooled. Occasionally I have had to stop a few minutes to let the engine cool, and there is no doubt that a certain amount of care is needful to prevent overheating. On the other hand there are of course advantages in air-cooling, especially in frosty weather. But the Lanchester car is now water-cooled, and I have had mine "converted" to water-cooling. There is no question that the water-cooling gives considerably more power (the makers say a rise from 10 to 12-h.p., but I should put it higher), and so far as I can judge at present, it is decidedly to be preferred. I should advise "Enquirer" to choose the water-cooled pattern. As regards range of speed and fixed ignition (3 and 4) there seems no need of a variable ignition on the "Lanchester." The ignition is automatically retarded at starting, so there is no danger of back-fire. As regards range of speed on one gear it may be sufficient to say that I can drive a Lanchester through London traffic without difficulty on the top speed. Either cylinder can be cut out, and no ill effects arise if one governor cuts out oftener than the other—it usually does. The governor is controlled either by hand or by foot, in the latter case both cylinders are governed together. I usually drive with the foot-governor. (5) The position of the control levers is quite convenient and they give no difficulty at night. The Lanchester requires less speed changing than any car which I have tried of similar horse power. I have driven nearly forty miles on Herefordshire and Worcester roads without having once to drop from highest gear, pace, of course, being regulated by a governor. The lowest of the three gears is very seldom required. (6) The ordinary adjustments, etc., of a Lanchester are very simple. Undoubtedly at first sight one is likely to consider the mechanism complicated, but the apparent complication gives very little trouble in practice. For example, to get at the valves is decidedly difficult, but in 16,000 miles I had only to touch the valves twice. I am my own mechanic (two years ago I knew nothing of engineering) and I never take a man with me on tour—an ostler or a friend's coachman can do all I want. (7) The change speed and brake are hand-operated. The high gear lever when pulled back releases the clutch and puts on the brake—suddenly or slowly as required. The low speed lever when pulled back first brakes and then reverses the car, but is not so speedy in operation. This arrangement gives a very effective control. (8) I have travelled over a great part of England and Wales and have never yet stuck on a hill on which I have had to shed a passenger. On the level the Lanchester is not so fast as many cars of 12-h.p., but I can easily average twenty miles per hour on the fairly hilly roads about here, and perhaps that is enough for safety on most of our country roads. As regards comfort there is no question. The seating is comfortable, there is no vibration (the engine is "balance") and there is room for a quantity of luggage which no other car can take—a most important consideration in touring.

This seems rather a "puff" of the Lanchester perhaps but I am in no way interested in the company, and simply give my own very pleasant experience of two years. I may add that when repairs have been needed, I have found the company very prompt and courteous. I would advise "Enquirer" to ask them to give him a trial run in one of their cars, I feel very little doubt that he will be satisfied.—Yours truly,

H. George Morgan.

To the Editor of *The Motor-Car Journal.*

Sir,—In answer to "Enquirer's" letter in your *Journal re* Lanchester experiences, I send the following replies. I have driven a 10-h.p. air-cooled Lanchester car for fifteen months, belonging to the Peninsular and Oriental Steam Navigation Co., and had previously, and have since handled several types of the ordinary car up to 24-h.p. (1) The tiller system of steering is undoubtedly quicker, surer, and more easy than the wheel. (2) Air cooling was not a success on the above car. (3) There is plenty of speed and power in the engine on either gear. (4) The governor control is quite equal to the throttle, I have driven the car for miles with one cylinder working all the time and the other governed so as to cut in when the speed dropped below a certain point; this was a great advantage, enabling me to cool each cylinder alternately. A throttle in addition would, I think, be an advantage. (5 and 7) The control and speed levers are very effective, as one always has one hand free to attend to the gears. The brake is the most powerful I have ever handled, but as an extra safeguard, band brakes should be fitted to the wheels, as in the event of the driving shaft breaking or coming adrift between the engine and worm gear, the brake would also be ineffective. (6) A little trouble at first to understand, but when the principle is understood very simple. (8) Hill-climbing wonderful, due, I think, to the heavy fly wheels and perfect balance of the engine; this also applies to the speed and comfort, which compare favourably with any car, power for power, at present on the market.

The above car has, to my knowledge, travelled at least 20 000 miles over very bad roads, and is out every day in all weathers and is like "Charley's Aunt" still running.—Yours truly,

H. J. Butler.

NON-SLIPPING TREADS.

To the Editor of *The Motor-Car Journal.*

Sir,—I am anxious to know whether in the case of having a non-skid device on one back wheel only, whereby such wheel is raised higher than the other one (possibly in some cases as much as half an inch), any injury can possibly be caused to the frame or springs, or other part of the car. Also whether a different adjustment of the back brakes should be made, and if so, to what extent.—Yours truly,

Enquirer.

To the Editor of *The Motor-Car Journal.*

Sir,—I read with interest the letters of your correspondents "Norfolk" and R W. Buttemer on the subject of the above, and I trust you will allow me space to add my experience during the last twelve months. To begin with, I have always found that bands which are vulcanised on are both inconvenient and expensive, and are not much required in the summer time, and when worn out they have to be cut off the cover, thus entailing additional outlay through the retreading of the cover. I have tried several non-skidding treads, but for all-round satisfaction and economy commend me to the detachable band supplied by the Glasgow Motor Tyre Company. One of these has done me good service over more than 2,000 miles on all kinds of roads, and is little the worse of wear. The band is of the ordinary chrome leather type but with solid steel studs consequently insuring a longer life. Another advantage which I have found it to possess over other bands is the extreme ease with which it can be attached and detached. I am sure that the former operation can be satisfactorily performed in four minutes at least, and the latter in less than one. There is yet another virtue

Digitized by Google

about this band, and it is one which would appeal to most motorists, that is, its modest cost. The one I am using at present is an old vulcanised band which the firm converted to their type at a small charge, and serves the purpose admirably; whilst there is no preceptible deterioration of speed to my car, which is of 24-h.p. I have no interest in this particular patented non-skidding tread, beyond the desire to acknowledge a felt want supplied.—Yours truly,

A Brother Motorist.

STARTING A CAR.

To the Editor of *The Motor-Car Journal.*

Sir,—I shall be greatly obliged if you can inform me of the reason my 12-h.p. De Dietrich car takes so much starting. I can only get it to start by advancing the ignition to the extreme limit, and even then it will only start very slowly, and after the handle is past the highest compression. The magneto has been overhauled by the makers and is in order. Will you kindly express an opinion?—Yours truly,

H.

[The trouble of "H." seems to point rather strongly to the fact of the ignition cams not being set correctly. If these were correct it would be almost an impossiblity to start the engine with the ignition fully advanced without disastrous results (from backfire), and we would advise a through examination of this, and ascertain if the time of spark is not somewhat late.]

ECONOMICAL RUNNING.

To the Editor of *The Motor-Car Journal.*

Sir,—Could you or any reader of the *Journal* tell me what average mileage per gallon I ought to do with Pratts' A motor spirit? The car is a four-seated one, and scarcely goes out with less than four passengers; the motor is a 1902 type 6½-h.p. Aster without governor.—Yours truly,

A Motor Driver.

EXPERIENCES IN SOUTH AFRICA.

To the Editor of *The Motor-Car Journal.*

Sir,—The following record of my 10-h.p. Argyll car may be of interest to you. I covered 1,949 miles, mostly over rough roads, with no failure or trouble. After travelling this distance I had my first accident, through colliding with an obstruction on the road. At 1,964 miles, I experienced my first tyre trouble (burst inner tube); at 2,130 miles, I struck a sand drift (sand over 9 in. deep) while running strong, damaged differential gear pinions and needed assistance for the first time.—Your truly,

Port Elizabeth. W. Roger Chew.

SIX VOLTS FOR IGNITION.

To the Editor of *The Motor-Car Journal.*

Sir,—I have read at different times of motorists who have experienced ignition troubles, and who have eventually surmounted the same by using a three-cell accumulator giving six volts in place of the usual two-cell four volt. I have lately been suffering from spasmodic firing, but have hesitated somewhat in adding another cell to my battery until I am sure that the induction coil will not be injured thereby. It wouldn probably be interesting and useful to other of your readers, as well as to myself, to have the experiences of those motorists who have used a six-volt current through the coils on their cars. I am told that the increased voltage effects marked improvement in the firing, and, consequently, the "life" of the motor.—Yours truly,

W. F. Rhodes.

ENGINE TROUBLES.

To the Editor of *The Motor-Car Journal.*

Sir,—Can any of your numerous readers inform me why my engine gives a sort of kick when running slowly? It is a single-cylinder 5½ to 6-h.p. Has it anything to do with the exhaust not freeing itself sufficiently soon enough? Any hint to overcome the difficulty will be much appreciated by—Yours truly,

Gerard.

["Gerard" does not mention whether the kicking occurs when his engine is running idle or when driving. We should be inclined to think that it was due to the engine being overworked at too low a speed when driving. A single-cylinder engine requires to be run at a rather high speed to obtain good results, and if the speed is reduced when the top gear is in, the kicking would certainly occur. If this is the case, the only remedy is to increase engine speed and lower the gears. In the case of the engine running idle the kicking may occur through a slight overheating causing premature ignition when running slowly, which would not be noticed when running fast.]

STEAM CARS.

To the Editor of *The Motor-Car Journal.*

Sir,—In your issue of October 8th I noticed letters *re* steam cars, signed by "J. R." and Mr. H. J. Rogers, in both of which it is stated that ordinary petroleum can be used by attaching some special kind of burner—the Morriss' system I think is referred to. Being the possessor of a steam car, and seeing that petrol out here in Cape Town is bought at not less than 2s. 6d. per gallon, I should be obliged if either of the gentlemen mentioned would enlighten me regarding the methods necessary for burning petroleum, and where full particulars as to the Morriss system can be obtained.—Yours truly,

B. B. B.

[We have asked Messrs. Morriss to send the necessary particulars to our correspondent.]

Motor-Cabs.—A hotel proprietor in one of the Home Counties wants the addresses of firms willing to supply motor-cabs.

Salsbury Lamps.—Messrs. Salsbury and Son, Limited, write to inform us that all Salsbury lamps have the word Salsbury on them, and that any lamps with the word differently spelt are not of their make.

The Rexette.—Referring to "Fosse Road's" statement in our issue of the 12th ult. as to this car, Mr. G. F. Heath, 49, John Bright Street, Birmingham, writes to say that he, on a 6-h.p. De Dion, would be pleased to give him, "Fosse Road," a chance of showing his heels.

Platinum Tubes.—A Liverpool firm having had several platinum tubes lately taken from cars in their motor garage, will be pleased to hear from any firm or dealer to whom they may have been offered for sale.

Stanley Show.—An umbrella left at the stand of the Hoffman Manufacturing Company, Limited, of Chelmsford, can be obtained by the owner on application to the firm, with a description of the article.

Folding Bicycle.—Replying to Dr. Teare's query in last week's *Journal*, the Dursley Pedersen Cycle Company, Limited, of Dursley, Gloucestershire, inform us that they make a folding (or military) type of bicycle. Mr. M. Turkheimer, Via G. Sirtoi 5, Via Lambro, Milan, is the maker of the military folding bicycle used in some Continental armies.

Motor-Car Repairs.—Referring to the remarks of correspondents in our last issue, with regard to motor-car repairers, Mr. R. Hazel sends a letter revealing a more pleasant picture. He recently had a bad smash with his 10-h.p. car at Hounslow, and, towing the vehicle to Messrs. Letzer and Jordan, at Kingston, had it repaired satisfactorily and economically.

THE HEREFORD LIGHT CAR TRIALS.*

By W. Worby Beaumont, M.I.C.E.

Thirty-eight cars were entered, and twenty-six, or 68 per cent., of them completed the trials, or 70 per cent. if we exclude one that did not put in an appearance. They were nearly all two-seated cars, as in 1900, yet the smallest of them had engines of 6 horse-power, or about 100 per cent. more power than the average of the little cars of 1899, and many of them had engines from 130 to 170 per cent. more powerful than the 3 horse-power of 1899.

Of the thirty-eight cars that entered for the trials there were thirty which had transmission and speed-change gear of the sliding type.

Two only were driven by side chains.

Five were driven by a single chain from engine to live axle.

Four were driven by single chain from countershaft to live axle, and of these

Three were driven by a chain from the crank shaft to first motion spindle in the gear-box.

Twenty-four were driven by a jointed propeller shaft from gear-box to bevel wheel on the live axle.

A considerable number of the cars had horizontal engines, most of them had single-cylinder engines of the De Dion make or De Dion type by other makers.

Of the thirty-eight cars entered, twenty-four, or 63 per cent., were of the live axle type, driven by a fore and aft propeller shaft and bevel wheel on the differential gear on the axle, as used by Renault in 1899. Some of these cars showed on examination that they had been *designed* in arrangement and detail, and carefully thought out on paper before they were put into the shops. Some, however, were very like a type of car not at the trials, which does no one any permanent good. The requirements for the design of this type of car are few. They are principally a component catalogue and an order-form book; and the design is carried out by two things, namely, a handy-man, erector, and a glossary of French and English terms. Cars designed in this way show themselves by numerous details—such as connecting-rods bent to escape things not noticed in the component catalogue, but which come in the way; lugs in various places that are not wanted or are not used; corners filed off to make way for something unforeseen; tanks in no way suiting the shape of the place they are made to take; disproportion of engine and cooler, of engine and gear, of car and brakes, and complications and indirectness not necessary in a designed car.

The 20-h.p. Thornycroft Char-a-banc which has been running between Lymington and Milford-on-Sea (a distance of sixty miles) daily for the London and South-Western Railway Company, for some time past. The car negotiates the Lymington town hill—1 in 10—easily upon its second speed with a full load of seventeen passengers and driver, in addition to luggage.

Generally, the cars at Hereford were of high class in design, and the average quality as good, or better, than that of the average big car.

Very few 12 or 15-h.p. cars would mount Frome's Hill in the style and at the speed that the 6, 6½, and 7-h.p. cars mounted it with two passengers.

The apparent mechanical efficiency of some of the cars was very remarkable, and it is worth while considering some of the particulars of their performance.

The speed of the ten fastest cars on Dinsmore Hill and on Frome's Hill up to the point at which the gradient became more than 1 in 7 was as given in the following table, which also gives the deduced efficiency. To determine the mechanical efficiency, a road resistance of 50 lb. per ton has been taken, and the air resistance r has been calculated by the expression

$$r = V^2 A\ 0.0017,$$

A being the area presented to air resistance in square feet, and V = velocity in feet per second.

Table I.—*Mechanical Efficiency of Ten Fastest Hereford Cars.*

No. of car. In order.	Official.	Name.	Declared b.h.p.	H.P. on hills.	Mechanical efficiency.
1	10	Wolseley	6.5	5.61	86.25
2	22	De Dion	6.0	5.19	86.40
3	14	Swift	7.0	5.12	73.20
4	15	Star	7.0*	5.42	77.50
5	18	Siddeley	6.5	5.16	79.40
6	20	Wolseley	6.5	4.75	73.10
7	26	Swift	7.0*	5.30	73.75
8	30	Croxted	8.0*	5.63	62.60
9	38	Star	7.0*	5.74	82.00
10	23	De Dion	6.0	4.24	70.75

* Two cylinders.

It may be said in criticism of these figures of mechanical efficiency that the brake horse-power used for comparison with the horse-power represented by the work done in hill climbing is an uncertain quantity, as only being the brake horse-power declared by the makers.

I have, however, checked the horse-power, which it is possible to do with a very near approximation to accuracy, from the engine dimensions and speed, and would, moreover, point out that some of the Hereford hill-climbing was such as would find out, on the one hand, any b.h.p.'s of the snatch test kind, while the 600 miles consumption test, if not absolutely accurate in each individual case, formed in the aggregate a good check on understatement of b.h.p.

Taking, then, the mechanical efficiency as found with a road resistance of 50 lb. per ton, it will be seen that they are remarkably good as compared with the results of previous trials and as compared with the results of the dynamometer trials conducted under the auspices of the Automobile Club of France by M. Forest and others. They show an advance which, in round figures, may be taken as from 65 to 80 in the last four years, or an increase on the figures of 1900 of at least 20 per cent.

The ten highest efficiencies are not confined to one class of transmission gear, four types being represented, and the three highest represent three distinct types, namely, Wolseley, De Dion, and Star.

Three of the fourth type, namely, the two Swifts and Alldays, come next, and although a good deal lower than the Wolseley and De Dion, are consistent approaches to similarity for the same class of drive, namely, the bevel drive on a live axle.

That the system of transmission is very far from being an index of performance is, however, shown by the difference in that of the two Wolseley cars and the two De Dions, a difference which was as noticeable in the "go" of the cars during the trials, as in the difference in mechanical efficiency deduced from them.

Such a difference as is shown by these two cars must show how very much performance by a particular class of mechanism may be affected by what may be called workshop differences which are difficult of detection. The difference, it will be noted, is not so great between the performance of the Wolseley and Siddeley cars as with the two De Dions. They also show how very unwise it may be to send a car which has not been run long enough to give opportunity for complete adjustment and run by the same driver for trial.

The highest mechanical efficiency is not always accompanied by the most economical performance. Thus the ten cars showing the highest mechanical efficiency change positions with regard to economy into the following order:—

Table II.—*Relative Economy of Ten Fastest Hereford Cars.*

No. of car. In order.	Official.	Name.	Miles per Gallon.	Total weight with passengers. lb.
1	14	Swift*	38.8	1512
2	18	Siddeley	38.5	1603
3	30	Croxted	33.3	1848
4	22	De Dion	30.3	1414
5	23	De Dion	30.3	1414
6	15	Star	29.5	1694
7	10	Wolseley	28.3	1596
8	38	Star	25.4	1908
9	20	Wolseley	24.6	1554
10	26	Swift†	23.6	1610

* One-cylinder. † Two-cylinder.

Several cars, not included in the ten fastest and of highest apparent mechanical efficiency, were among the most economical, namely, the Clyde, with 47.2 miles per gallon, a result which seems to show some error in the petrol account, which, however, could not be detected; the 6½-h.p. Royal Humberette, with 37.9 miles per gallon; Alldays 7-h.p., with 34.5 miles per gallon; Alldays 7-h.p., total weight 1533 lb., with 33.3 miles; 8-h.p. Brown, with 31.4 miles; the 6-h.p. Jackson dogcart, total weight 1,330 lb., with 28.5 miles; Prosper Lambert 8-h.p., total weight 1,890 lb., with 27.2 miles; and the 6-h.p. Speedwell, total weight 1,309 lb., 25.8 miles.

With regard to transmission gear, one of the cars which commenced the trials but had a mishap breakage, namely, the Downshire car, presents

* From a paper read at the A.C.G.B.I. on November 24th, 1904.

Digitized by Google

a point of some interest with respect to chain stress. The chain used runs from engine shaft to gear on the live axle. The lower speeds are effected by change of gear driven by the chain and not by gear driving it. The pull on the chain is therefore not increased as in arrangements adopted in some other cars with a single chain, in which the speed change is made in the gear driving the chain.

An examination of the economy figures will show that there cannot be any doubt that in many cases consumption is a function of the skill and constancy of attention of the driver. It may, however, be noticed in passing that while the two De Dion cars, differed considerably in apparent mechanical efficiency, their consumption was identical, while the two Wolseleys, which differed so much in apparent mechanical efficiency, differed in the same order in consumption, which would seem to indicate similar care on the part of the drivers in this respect.

THE NEW CLEMENT-TALBOT WORKS.

On Friday last week we had an opportunity of inspecting the magnificent new works which Messrs. Clement-Talbot, Ltd., have erected in Edinburgh Road, Notting Hill, W., for the manufacture of the Talbot car in this country. The general and drawing offices, together with the engine and show rooms, consist of a large separate building, having a handsome frontage to Edinburgh Road, with an indrive to the portico giving shelter to vehicles approaching the central main entrance. By this entrance visitors gain admittance to the grand hall, which has a mosaic pavement and rich and tasteful marble decorations. A few steps on the right admit to the central corridor of the right wing, which has on the right the administration offices, and on the left an extensive and well-lighted drawing office. The entrance hall also forms a showroom, where visitors will be able to inspect finished cars, chassis, and accessories. A handsome pair of plate-glass swing doors on the left open on to a balcony within the engine-house, which at present contains a Willans and Robinson 150-h.p. vertical gas engine and dynamo, and a 14-h.p. gas engine for starting purposes. Space is available for the installation of two other sets of 150-h.p. engines and dynamos, which are to be added later. A gallery across the south side of the engine-room, accessible from the entrance hall, gives access to the heating chamber and to the stock-room, and beneath these are a workshop and millwright store. Separated by a roadway at the rear is an exceedingly large single-storey building, divided into four departments, two of which have been equipped with machine tools of the most modern kind, under the supervision of Mr. C. R. Garrard, the works manager. The third is devoted to fitters and to repairs, while the fourth is an erecting shop and stores for finished material. The machine tools are electrically driven by independent motors or in groups from the usual line shafting, the motors being supported in an inverted position overhead, so economising floor space. Detached from the main works is the producer gas plant for supplying the gas for the engines, while close to it is a separate building, comprising the testing, smiths', and case-hardening shops. The heating arrangements are particularly worthy of notice. The offices are heated by means of the engine-cooling water, which is led from the engines to jackets round the exhaust pipes, and thence to a superheater, which can be heated by gas. The hot water thus obtained is taken by a system of pipes and radiators throughout the rooms of the administration building. The works section is warmed by air forced by a large fan through a bank of pipes, which is in direct contact with the flames from the producer gas furnace. Some idea of the extent of the works may be gathered from the fact that the site covers over five acres. A large part of this has already been covered, and at an early date it is intended to add a building fully equipped for carriage bodywork, painting, and upholstering. It may also be mentioned that a track for testing cars extends right round the works. Operations have already been commenced on various parts of the Talbot cars, but gradually the construction of the complete vehicles is to be taken in hand, and although they will be identical with those built by M. Clement in France, the material and workmanship will be entirely British.

The annual trade dinner of Messrs. Clement-Talbot, Ltd., which was held in the evening, practically formed the formal opening of the new works, one of the shops having for the occasion been converted into a handsomely-decorated dining-hall. The Earl of Shrewsbury and Talbot, the chairman of the company, presided, and he was supported by M. A. Clement, M. A. Lucas, and M. Lamberjack, directors; Mr. D. M. Weigel, the managing director; and Mr. C. R. Garrard, works manager. Owing to the inclement weather, the number of agents of Clement-Talbot cars present was not so large as was expected, but the ninety or so gentlemen who braved the elements spent a most enjoyable evening. After an excellently-served dinner, Earl Shrewsbury, in proposing the toast of "The Automobile Industry," gave some particulars of the new works, and stated that the purchaser of a motor-car of to-day was much better off than the man who bought his car two or three years ago, for manufacturers were now producing a more scientific machine. That their trade was a real industry was demonstrated by the fact that omnibus companies were making trials and railway companies using automobiles to feed their lines. As to the question of speed, he was of opinion that the day was passed when people bought cars in order to make them travel as fast as they could, and that nowadays they looked for a car that would go as far as was desired. People in the country did not object to motor-cars to such an extent as was the case a year or so ago. In his own county of Shropshire the council, instead of fining motorists, had recently decided to erect 100 warning signs, and at one place, where an unfortunate accident had taken place, the owner had given sufficient land to prevent a repetition. The toastmaster then called upon "Mr. Wiggle," otherwise Mr. Weigel, to propose the toast of "Our Agents," and, in the course of a short speech, the latter stated that, whereas the sales of Clement-Talbot cars in the 1903 season only amounted to fifty-four vehicles, no less than 325 had been disposed of during the past season, mainly through the agents. He referred to the growing trade with the colonies, particularly Australia and India. He also announced that a prize of 100*l.* in cash was being offered to the agent or sub-agent of the company in the United Kingdom who during the year ending October 30th, 1905, shall have driven a Talbot car the longest distance at the best average mileage per hour in accordance with certain rules and regulations. The latter provide (1) that more than one person may act as driver; (2) in the case of a four-cylinder car all four seats shall be occupied, and in the case of a two-cylinder car at least three seats shall be occupied, during the whole period of the run; (3) during the run the engine must not stop, or be stopped; when the engine from any cause whatsoever ceases working, it will be considered that the total run by the driver and car has been accomplished, and his chance of gaining the prize will be the length of his journey up to that moment; (4) any agent, or sub-agent, while competing must drive in the county in which the district he is appointed for is situated; (5) every intending competitor shall give at least one week's notice to Messrs. Clement-Talbot, Ltd., of his intention to compete prior to the commencement of his attempt; (6) the legal speed as recognised by the public authorities not to be exceeded by any competitor. The prize will be presented to the winner at the next annual trade dinner. Mr. Millburn responded for the colonial agents, and Mr. Hollingdrake, of Stockport, for the home agents, the latter amusing the company by a story of a Welshman who gave evidence that a Clement car had travelled past him at a speed "of hundreds and hundreds of miles an hour"! Other toasts followed, including that of "Our Chairman," given by M. Clement, and that of "The Press," proposed by Mr. Cox. The hour being somewhat late, a hurried run round the works was made, following which the party gradually broke up, after spending not only a pleasurable but a most instructive evening.

CLUBS AND ASSOCIATIONS.

AUTOMOBILE MUTUAL PROTECTION ASSOCIATION.

Meetings of the Council, Finance and General Purposes Committee, and Mechanical Transport Committee of the Automobile Mutual Protection Association were held at the Royal Agricultural Hall, Islington, on November 24th.

The Earl of Shrewsbury and Talbot (President) was in the chair, and there were also present Messrs. W. E. Rowcliffe (Hercules Motor Wagon Company), Walter H. Maudslay (Coventry), Henry Spurrier, junr. (Lancashire Steam Motor Company), J. R. Richardson (Lincoln), Charles Holmes (Holmes-Prunel Company), D. M. Weigel (Clement-Talbot, Ltd.), Jno. H. Toulmin (P. Coulthard and Company), E. Lisle (Star Engineering Company), A. Pereno (Farman Automobile Company), Wm. Deighton (Yorkshire Patent Steam Wagon Company), Mawdsley Brooke (Lowestoft), and W. R. McTaggart (Dublin).

Mr. W. H. Maudslay, of Coventry, was elected Chairman of the Mechanical Transport Committee which was occupied with the proposals of the Automobile Club in respect of the heavy commercial vehicle competition to be held about a year hence. It was decided that the exact date must depend upon the issue of the Local Government Board Regulations, which are now expected to appear before the Christmas vacation, and to recommend that the trials be held during the first half of September next, in preference to their being postponed to the spring of 1906, provided the regulations do appear before January 31st, 1905.

A communication from the Automobile Club Committee, in which the Association were invited to make nominations to the Industrial Committee of the Automobile Club, was considered. In view of the importation of the suggestion that the action of the Association in proposing an alteration in the method of procedure for constituting this Committee was in any way personal (*vide* "Automobile Club Journal," November 10th, page 346), it was unanimously resolved that no nominations should in any event be made until the date of the general meeting of the Automobile Club in March next. It was also decided to point out to the Automobile Club that the suggestion of the Association was one of principle which called for acceptance, or rejection, as a whole, before the question of nominations could arise, and that if the elected representatives of the trade, to be chosen by the trade to represent the trade upon the proposed modified and jointly-constituted committee, were really to represent the trade, they must be accepted by the club as members of such committee without any right of rejection by the club committee.

The following were admitted members of the Association, being Nos. 177 to 181 on the register:—The Highgate Implement Works, Limited (Tweedmouth), the Victoria Carriage Works, Limited (London), the Coronet Motor Company, Limited (Coventry), the Phœnix Motor Company (Southport), and Messrs. Moss and Woodd (London).

MANCHESTER.

The Manchester Automobile Club have had their second House Dinner at the Midland Hotel, with an attendance of about sixty members and friends. The chairman, Mr. Frederic Smith, presided.

Digitized by Google

After dinner discussion took place on the necessity for, and the merits of, non-skidding devices now on the market. The general opinion was that such devices were necessary, and that all of them more or less prevented skidding, and in some cases protected the tyre also, but all were expensive in upkeep. Mr. Holroyd Smith interested those present in his spring hub wheel, one of which he dismantled so as to show and explain the working of the springs and mechanism. M. L'Empereur, the inventor of the non-skid bearing his name, was also present as the guest of one of the members.

MIDLAND.

In the Sunrising Hill-climbing Handicap held in July there were thirty-one entries. The order of merit of the first score has been determined as follows :—

Result.		Owner.		Make.
1	...	W. H. Cook ...	...	10-h.p. Argyll.
2	...	P. Martin ...	...	28-h.p. Daimler.
3	...	A. Farnell ...	...	28-h.p. Daimler.
4	...	E. Manville ...	...	28-h.p. Daimler.
5	...	E. M. C. Instone	...	28-h.p. Daimler.
6	...	E. M. C. Instone	...	28-h.p. Daimler.
7	...	A. J. Dew ...	...	24-h.p. Leon Bollée.
8	...	S. F. Edge ...	...	20-h.p. Napier.
9	...	Miss Forrest ...	...	40-h.p. Mercedes.
10	...	G. F. Reading ...	...	10-h.p. Wolseley.
11	...	Major Lloyd ...	...	6-h.p. Wolseley.
12	...	Lionel de Rothschild ...		60-h.p. Mercedes.
13	...	Anglo-American M.C.		6½-h.p. Cadillac.
14	...	T. Thornycroft Co., Ltd.		20-h.p. Thornycroft.
15	...	Rover Cycle Company		8-h.p. Rover.
16	...	J. H. Deykin ...	...	6-h.p. Wolseley.
17	...	Cecil Edge ...	...	14-h.p. Gladiator.
18	...	Jersey de Knoop	...	24-h.p. Leon Bollée.
19	...	Wolseley Company	...	6-h.p. Wolseley.
20	...	C. S. Baynton...	...	10-h.p. Wolseley.

COACH v. MOTOR-CAR.

Before Mr. Justice Lawrance and a common jury, in the King's Bench Division, a case has been heard in which Messrs. S. Goff and Co., coachbuilders, Long Acre, W.C., sought to recover from Messrs. T. Tilling (Limited), jobmasters and omnibus proprietors, damages for injury to a motor-car. The defendants denied negligence and alleged contributory negligence. Mr. Salter, K.C., in opening the case, said that the old-fashioned coach and four was in fault, though, perhaps, the fact that the occurrence took place on Derby-day was a sufficient explanation. On that day the plaintiffs' manager, with a driver and three friends, went in the car to call upon a likely purchaser at Epsom. On arriving at Ewell they saw coming towards them "a mob of traffic" returning from the Derby, and, acting on instructions, the driver pulled up by the kerb on his near side and kept the car at a standstill in order that the traffic might pass. A char-a-banc was in the middle of the road, and a wagonette on the off-side, and when they got near the motor, a four-horse coach belonging to the defendants drew out from the back of the char-a-banc and attempted to pass to the front. The leaders got through, but the wheelers were unable to do so, the result being that the pole of the coach smashed into the motor-car, overturning it on to the pavement and practically wrecking it. After hearing evidence the jury found for the plaintiffs and assessed the damage at £230.

MOTOR-CAR v. BRIDGE.

In the City of London Court, the Regent's Canal and Dock Company have sued Mr. Walter Morford, of Hampstead, for £7 12s. for damage done to Renter's Bridge, Hendon, by the defendant's motor-car. On April 17th the defendant was crossing the bridge over the River Brent when his motor-car ran into the wooden parapet, carrying it away, the car, with the defendant and two friends, falling into the river. The passengers scrambled out as best they could and the car was removed the next day. The plaintiffs, having on them the duty of keeping the bridge in proper repair, now sued the defendant for the damage done. The defendant said that the bridge was a dangerous structure and, in fact, a death-trap. He had defended the action principally so that the public might be warned against the bridge. Mr. Bevan, plaintiffs' counsel, said that was a matter for the local authority and not for the plaintiffs. Owing to the greatly increased traffic since the bridge was built in 1851 it had probably become a nuisance, but that was not the plaintiff company's fault. Judgment was given for the plaintiffs for five guineas and costs.

NO NEGLIGENCE PROVED.

At the Marylebone County Court on Friday last week, before Mr. Fitzroy Cowper and a jury, John Whittaker, Shepherd's Bush, W., brought an action against Mr. W. Carpenter, Willesden Green, N.W., claiming £50 in respect of personal injuries, said to have been sustained through the negligent driving of a motor-car by the defendant. The plaintiff stated that on 19th April last he was riding his bicycle along the Barnet High Road, on his near side. On approaching the "Bull and Butcher" public-house, he heard the hooting of a motor-car behind him. A little further on a portion of the road was being repaired; there was, however, ample room for the motor-car to pass the bicycle. Plaintiff kept straight ahead, but a moment later the motor-car "bashed" into the back of the bicycle, knocking him to the ground. After the accident the driver of the car (the defendant) paid 10s. to the man who repaired the bicycle.

The defence was that the plaintiff "wobbled," and then stopped just in front of the motor-car; and that the 10s. was paid to the bicycle repairer on the understanding that defendant should not be called upon to pay more. The jury did not consider that negligence had been proved against the defendant. Judgment was accordingly given for the defendant, and his Honour allowed costs.

POLICE TRAPS.

A measured 220 yards at Whetstone, on the Great North Road, is utilised by the police for trapping motorists.

Motorists should remember that even the parks are not free from police traps. There is a measured distance in Hyde Park, and the Earl of Portarlington was caught therein the other day.

A MOTORIST ACQUITTED.

At Maidenhead, on Saturday, Stanley Noble, of the Swan Hotel, Lancaster Gate, W., was charged with feloniously killing a little boy named Thomas E. Overall. At the inquest on the boy on November 7, the jury returned a verdict of "Manslaughter" against Noble, who was alleged to have been the driver of the motor-car which knocked Overall down on November 4 at Hurley, causing his death four hours after from fracture of the skull. The Treasury prosecuted, Mr. F. I. Williamson appearing on their behalf, and Mr. Freke Palmer defended. The prosecutor called most of the witnesses who gave evidence at the inquest, and they repeated their testimony. The little boy Ridley, who was playing with Overall and another boy, failed, however, to identify Noble as the driver of the car. The prisoner was with his father in one of two cars which came from London to Henley, and passed the spot where Overall was knocked down about the time specified. After a long hearing the chairman said the magistrates did not consider there was a prima facie case to send for trial, and Noble was discharged.

CASES AGAINST MOTORISTS.

Place.	Summoned for	Fine.
Marlborough St., W.	(1) Beyond regulation speed in Hyde Park; and (2) not producing licence	(1) 20s., etc.; (2) 5s., etc.
Bow Street, W.....	(1) Beyond regulation speed in Green Park; and (2) not producing licence	£7 and 4s. costs for the two offences.
Hull	Obscured number	5s.
Coleshill	Driving dangerously	£10, etc.
Birmingham	Making unnecessary noise with motor-'bus outside King Edward's Grammar School	5s., etc.
Kingston	Beyond regulation speed in Richmond Park	£2, etc.
Highgate	Not producing licence	5s., etc
City of London	No lights	5s.
Saunders-foot	Refusing to stop when requested	£1, etc.
Penryn (Cornwall)...	Driving without licence	£5.
Newport (Isle of Wight)...	Driving furiously	Dismissed
Bournemouth	Dangerous speed	5s., etc.
Dundee.....	Reckless driving	£2, etc.
Wolverhampton.....	Reckless driving	£10, etc.

TO CORRESPONDENTS.

All communications intended for insertion in this Journal or relating to Editorial matters should be addressed to The Editorial Department, Motor-Car Journal, *39 and 40, Shoe Lane, London, E.C., and must be written on one side of the paper only. Letters must in all cases be accompanied by the name and address of the writer, as no notice will be taken of anonymous communications.*

The Editors cannot undertake to return MSS. or drawings, although every effort will be made to do so in the case of rejected communications. Where such are regarded as of value, correspondents are requested to retain copies.

To insure insertion communications and contributions must be in the Editor's hands by Tuesday forenoon of the week in which the same are intended to appear. Disappointment may be caused by non-compliance with this rule, and to avoid this earlier receipt, if possible, is necessary.

The Editors do not hold themselves responsible for the opinions expressed by their correspondents, or for statements and facts which do not appear in the editorial columns.

THE

Motor-Car Journal.

VOL. VI.] LONDON, SATURDAY, DECEMBER 10, 1904. [No. 301.

Published Weekly by CORDINGLEY & CO., 39 & 40, Shoe Lane, London, E.C.

COMMENTS.

SO many sportsmen have ordered motor-boats for next year that a very busy season may be confidently anticipated. In our immediate circle we know of eight gentlemen who have decided to become owners of such craft, the delivery of orders to take place early in the 1905 season. There is no doubt that the pastime on the water will become as popular as on the land, and those who intend to enjoy its realisation at no too distant a date should not long delay making their wishes known to the builders of motor-boats, so that disappointment may not be experienced. The provisional Committee of the British Motor Boat Club has already got to work, and has a proposition before it to organise a motor-boat race on the Thames from Putney to Mortlake, just previous to the starting of the University Boat-race.

◆ ◆ ◆

Trials for Motor-Boats.

MEANWHILE arrangements for the second annual Reliability Trial for motor-boats fitted with internal combustion engines are well forward, and although the actual date of the event has not yet been definitely fixed, the provisional rules are now in circulation and may be obtained from Mr. Basil Joy, the head of the Technical Department of the A.C.G.B.I. There will be six classes, as provided by the Marine Motor Association regulations, with beam and freeboard restrictions as follows:—1. Yachts' dinghies (clench built) not exceeding 15 ft. over all. 2. Yachts' launches (clench or carvel) not exceeding 20 ft. over all. 3. Yachts' launches (clench or carvel) not exceeding 25 ft. over all. 4. Yachts' launches (clench or carvel) not exceeding 30 ft. over all. 5. Unrestricted vessels of any description propelled by internal combustion engines, and not exceeding 25 ft. over all. 6. Unrestricted vessels of any description propelled by internal combustion engines, and exceeding 25 ft. over all.

◆ ◆ ◆

Petrol on the River.

AT Monday's meeting of the Thames Conservancy Board a report was received from the Harbour Master of the Upper District stating that on November 23 last the sailing barge Dreas was moored off East Greenwich with 150 cases of motor spirit on board, and there was a fire in the cabin; that the spirit had been taken from a wharf at Silvertown, and the vessel was to complete her loading at Harrison's Wharf, Wapping, and then proceed to Sandwich. The Lower River and General Purposes Committee reported in regard to this matter that, as the petroleum bye-laws did not apply to the case, it being one of exportation, and having regard to the great risk, they had addressed communications to the Board of Trade and Home Office on the subject. A reply had been received from his Majesty's Chief Inspector of Explosives stating that he agreed that the case afforded another instance of the necessity for the amendment of the Petroleum Acts; that unfortunately the difficulties of getting an amending Act passed were very great, and it would certainly be impossible to bring in a Bill during next Session. In view of the gravity of the matter the committee had requested the chairman and the secretary to interview the Board of Trade thereon.

◆ ◆ ◆

Experts on the Bench.

THE idea of having nautical advisers to sit with the judge in the Admiralty Court when considering cases of an extremely technical nature is apparently to be adopted in other expert matters. It is one that commends itself to common sense, hence the diffidence with which it may be regarded by the legal profession generally. But the precedent set by Judge Addison at the Southwark County Court the other day is notable, and marks an advance that should be welcomed by automobilists who are unfortunate enough to be engaged in litigation. The judge was hearing a case in which the defendant was sued for the price of work done to a motor-bicycle, and several points of a technical character were introduced. To thoroughly understand these his Honour invited a motor expert to sit with him and explain the technicalities that were raised. With such help he was better able to understand the intricacies of the case—a procedure of novelty and value.

◆ ◆ ◆

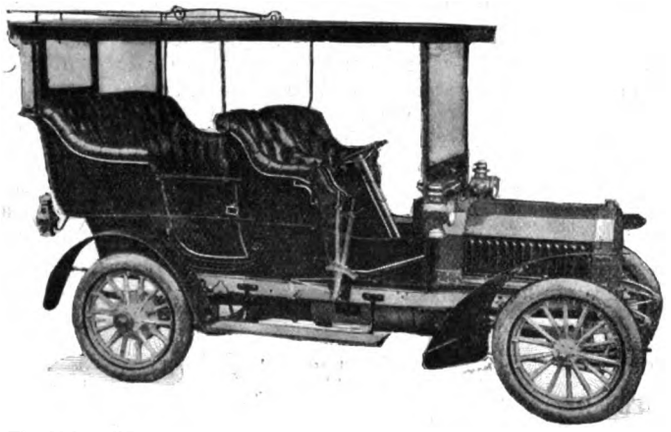
The Renewal of Licences.

IN the month of January last about 12,000 licences were issued to drivers of automobiles. These will have to be renewed shortly, a fee of 5s. accompanying each application for a renewal. In view of the fact that the work entailed by such a task will be exceptionally heavy in London, the Clerk of the L.C.C. has suggested to licence-holders in his district that the renewal should take the form of a separate document to be attached to the existing licence. He recognises that some time may be occupied in the process of renewing licences at the office, and that some inconvenience would probably be caused to the holder of a licence if he did not have it in his possession when required by the police. Hence the suggestion that a separate document to be attached to the licence will save possible irritation to motorists in London.

◆ ◆ ◆

A Scottish Conference.

AN important conference has taken place between the Secretary for Scotland and the Perth County Road Board with reference to proposed regulations for prohibiting or restricting motor-car traffic in the county. After the representatives of the various districts had spoken their minds—and some of them were very emphatic in the expression of their views—Mr. R. J. Smith, the hon. secretary of the Scottish Automobile Club, elicited the fact that restrictions were to be permitted in some populous places and at some dangerous crossings, in addition to the closing of the Trossachs road. He went on to suggest that the Act should have a further and more extended trial and that greater value should be placed on Section 1 of the Act, combined with a judicious use of caution boards. His Club did not oppose restrictions which were



Digitized by Google

regarded as reasonable, but they did desire uniformity in practice throughout Scotland. Mr. Robb also made a strong plea for a reasonable attitude on the part of the local authorities, being supported in this by Mr. Jeffreys, of the A.C.G.B.I.

◆ ◆ ◆

Views of the Secretary for Scotland.

MR. GRAHAM MURRAY, in his reply, did not disguise from them that he thought a good many people had taken a wrong view of the fact. They had treated the matter as one of local option. It was not that, for this very simple reason, that one talked of Perthshire roads because they were in Perthshire and were kept up by Perthshire rates, but they were really His Majesty's roads, and every citizen of the United Kingdom had as much right to use them as anybody in Perthshire. One remark was made that day with which he agreed as being of the highest importance, and that was that, so far as possible, the practice should be uniform. Of course it could not be uniform in the sense that circumstances in different portions of the Kingdom varied very much, and as circumstances varied the application of principles should vary. But that one should go on a certain determinate line was absolutely necessary for everybody's advantage and convenience. Accordingly, with that view, he came down and perambulated the roads, not really so much for his own information, because, if he might say so, he was rather

The 20-h.p. "Dennis" Car, with Roi des Belges body, recently supplied to Sir Alfred Watkin, Bart.

interested in the roads in Perthshire, and had driven over them all his life. Nothing but extreme necessity would justify the shutting of a road altogether, and in the question of applying the ninth section the test was whether practically, in all circumstances, it would be wrong to have more than ten miles an hour, because, so far as the actual interfering with or taking up of the person driving to the danger of the public was concerned, the principal weapon in the hands of those having anything to complain of in the way of reckless driving was section ten. He had to consider the suggestions made to him with regard to particular places; at the same time he had not heard anything that would in any way make him depart from the carefully considered opinion he had formed on the general principle. He should see that the actual determinations were given to them very soon.

◆ ◆ ◆

General Advice.

PASSING on to the general question, the Secretary for Scotland observed that those who had a great dislike for motors must not think that he did not have a considerable deal of sympathy with those who had to suffer from what was a new and in many cases a terrifying form of locomotion. The only hope he could give to those people was that no doubt time would to a great extent cure that. Within a radius of fifty miles of London horses were now accustomed to motor-car traffic, and it was almost unknown for them to take any notice of them. Out of that radius many horses were frightened. They had suffered terribly in the past from the very inconsiderate behaviour of a great many people who had charge of motor-cars. That was almost inevitable, especially in the case of hired servants; but he hoped there was already a considerable improvement in that matter, and he was sure there would be a still greater improvement in the future. The other remark he would like to make was with regard to the boards that should be put up. He suggested to the County Council that as far as possible the boards should be put up on a particular side of the road. That, he understood, was dealt with in the Scottish Office regulations, and no doubt would be attended to. The great thing was to put the boards where they would be seen, and that, he thought, would really solve the night problem as well, because, although the lights spoken of might be a bit annoying in their way, they would have great power in allowing motorists to see the boards.

◆ ◆ ◆

Improving the Roads.

FROM Falmouth we learn that the county authorities have ordered that all main roads in the county of Cornwall shall be steam rolled in future, and apparently such erring bodies as the Helston Rural District Council, whose shortsightedness led to the closing of the Great Western Railway public service a few weeks ago, will have to be reasonable. Just as some of the most prosperous seaside towns have seen well to advertise their merits and devise popular attractions, so the county authorities can do something to promote the prosperity of the country-side by seeking to draw motorists and others to their main roads. Thus there is real economy in such an expenditure.

◆ ◆ ◆

The Dust Nuisance.

THE weather of the last few days has robbed the address of the Hon. J. Scott Montagu, M.P., to the A.C.G.B.I. on the dust problem of much of its appropriateness at the present season. But in the greater part of the year the question of dust is a pressing one, especially when the winds blow strongly. We need not dwell upon the advisability of laying the dust, but would rather pass to the palliatives mentioned by Mr. Montagu. Many local authorities had made experiments, and although great benefits had been secured for a time, they were only temporary, and the cost of frequent renewal would be prohibitive. It had been observed, however, by the medical officer of health of Edmonton that in the area treated with one of these palliatives there had been a marked decrease of summer sickness among children. It was, of course, common knowledge that much of the disease of towns arose from the dust in the air, and those who advocated the construction of dustless roads could do so on the ground of the health of the community, and quite apart from any question of automobilism.

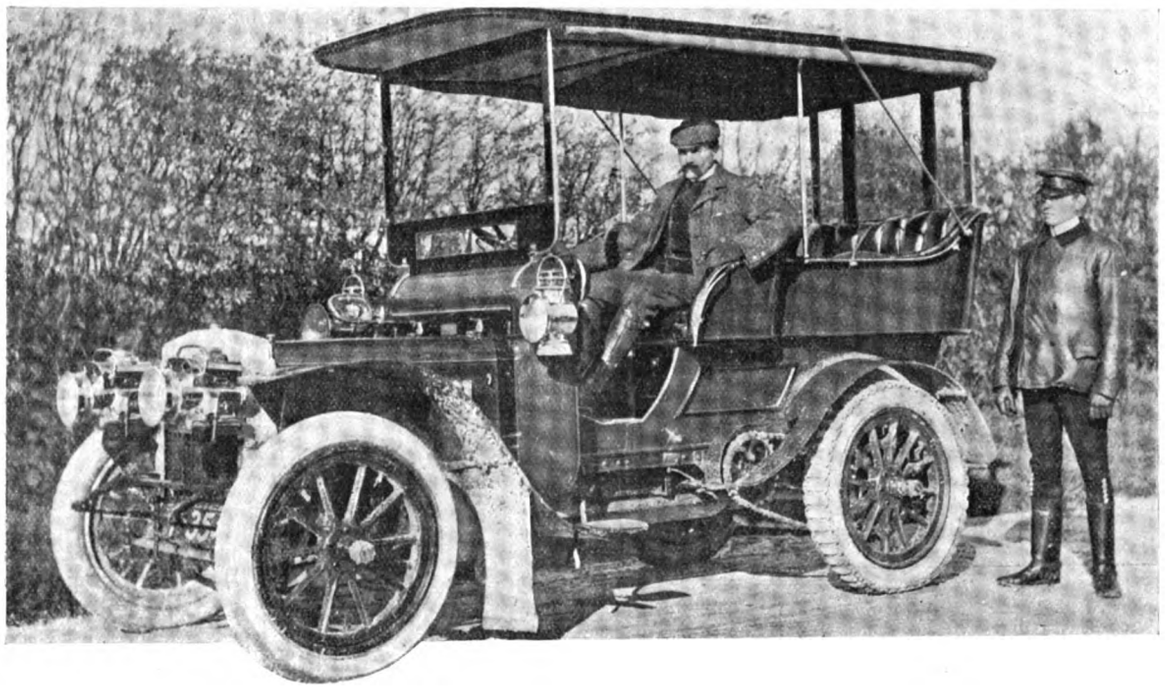
◆ ◆ ◆

Palliatives.

HE explained that road authorities when relaying and repairing road surfaces would not find it much more expensive to employ some dustless preparation such as tarred slag than the ordinary quartzite or granite at present used. Where it is not possible to so relay or repair the roads, he suggested that some such preparation as Westrumite or Akonia should be employed. Watering should be at once stopped, as it was most destructive to the road surface and binding material, entailing thousands of pounds in repairs. The different experiments which have been tried with fluids and tar preparations were then dealt with, the speaker advocating the adoption of a permanent cure wherever possible. To all appearance the material known as "tarmac," invented by Mr. E. P. Hooley, county surveyor of Nottingham, promised to provide an entirely satisfactory road. It consisted of slag steeped, as it came hot from the furnaces, in tar, which it absorbed until it was entirely permeated. This had been laid down in several places, and bade fair to justify the claim made for it, that it would cost little

Digitized by Google

more to use, would effect a saving in cleaning, and would last five to ten times as long as the ordinary roads.



◆ ◆ ◆

Provincial Clubs.

THE Yorkshire and Nottingham automobile clubs have been holding most successful annual festive gatherings. At the latter, the resignation of Mr. A. R. Atkey, who has worked loyally for the movement as hon. secretary, was made public, to the great regret of the members, who were prompt to testify to their esteem. At the Yorkshire gathering Mr. A. M. Bosville, who was in the chair, touched upon the controversy as to British and foreign cars, which has lately excited so much discussion in our columns. "We want," he said, "a giant of designers; we want a Stephenson and Brunel for the motor-car industry of this country. Then, with English work and English business push, there is no reason why the market should not turn round, and why English motor-cars should not be the best in the world." In the meantime, we can only go on telling manufacturers that people nowadays take speed,

Revision Necessary.

SUCH is the law, which, in this case, is a very different thing to common sense. According to the Act the general identification mark "may be used for any car on trial after completion or on trial by an intending purchaser." The intention evidently was that the mark should cover motor vehicles running for the sake of sale, and those which were merely the stock-in-trade of the dealer. But the way in which some magistrates have strained the Act has made it dangerous for firms to send their vehicles out at all. "On trial after completion" is a term which might well be construed as "until sold," and the general identification mark be regarded as sufficient registration. In the case of a trader who has had a vehicle in his showroom a week or two it is natural that he should want to run it upon the road before risking it with a probable purchaser. This, according to the view of some magistrates, may not be done with safety—an anomalous position that should be considered when the revision of the Act takes place.

Mr. E. C. Wills on his car in a Bristol Bye-way. (See page 848.)

hill-climbing, reliability, and all that sort of thing as absolute matters of course. What they want to turn their attention to are such things as silence, ease of control, and, above all things, the high-bred paces of a motor vehicle, and the luxurious fittings of the car.

◆ ◆ ◆

Private v. Trade Cars.

EVEN after nearly a year's experience there seems some confusion in the minds of many motorists as to the right use of cars bearing the general identification mark that registering authorities are permitted to issue by the Motor Car Act. In a case just heard in a London police-court the defence was that a car had been used for testing purposes and trial runs bearing the general identification mark. It was acknowledged that such a practice might have been indulged in for months. The magistrate pointed out that the Act of Parliament said nothing about using cars for testing purposes. They must be used with a general identification mark only when on trial with an intending purchaser, or on completion, but when used as the defendant had used the one in question they ought to be registered as private cars.

Universal Lights.

A DEPUTATION from the General Committee of the Motor Union will be received at the Home Office on Tuesday next, with regard to the universal lighting of vehicles on the roads. This is a subject that is fast becoming of prime importance to all who use the highways, and now that automobiles have to carry lights it seems but reasonable to require that the slower moving vehicles be similarly discernible at night. Legislation in this direction would be generally welcomed.

◆ ◆ ◆

Influence of Motor-car driving on Character.

A PATHETIC letter from the wife of a motor driver has reached us, in which the writer says that until her husband became a *chauffeur* he was kind and steady in his character; now, after a year's experience as a motor-car driver, he has become wayward, dishonest, irregular in habits, and is possessed of many bad qualities that were never previously suspected in his conduct. She is afraid that frequent absences from home have disturbed his nature and altered his disposition. There is no doubt that motor car driving with employers who require frequent

Digitized by Google

stays in the country does unsettle men, and hence such places are best filled by single men. Such service is necessarily irregular and cannot be subordinated to any time-table. It may therefore be quite possible to imagine that matrimony is a state ill suited to some mechanicians who are likely to be frequently from home.

◆ ◆ ◆

The Tourist Trophy.

THE commission of the A.C.G.B.I. appointed to suggest regulations for the organisation of a competition for the Tourist Trophy have reported in favour of the event being held between May and October in each year. The contest will take the form of a race for touring cars with a limited quantity of fuel, the distance to be not less than 150 nor more than 250 miles. The fuel will be petroleum spirit of a specific gravity of 0·695 to 0·705 at 60 deg. F. The weight of the *chassis* allowed will range from 1,300 lbs. to 1,600 lbs.; the load to be carried, including passengers, being not less than 950 lbs. Not more than two entries from one maker will be allowed, and the Commission recommend that the first race shall be held in the Isle of Man during September next.

◆ ◆ ◆

Mr. Gordon Stewart, J.P., Chief Officer of the Johannesburg Fire Brigade, on his 6-h.p. De Dion-Bouton Car. A small fire extinguishing apparatus is carried on the Car.

◆ ◆ ◆

An Australian Trial.

SOME thirty cars are expected to participate in the motor-car reliability run to be held from Sydney to Melbourne during February of next year The event is already attracting considerable interest throughout the colonies, as it will be the first great effort organised on lines which have been familiarised at home for some years. The entries are to close on the 28th January, and the itinerary with the time and speed allowances will be as follows:—Sydney to Goulburn, 129 miles. Heavy cars (over 1,200lb.),8 hr. 45 min. (average speed 15 miles per hour); light cars (1,200 lb. and under), 10 hr. (average speed 13 miles an hour). In each class 30 min. will be allowed contestants to drive from Sydney to Ashfield (five miles). No car will be permitted to leave Ashfield before expiration of half hour. Goulburn to Gundagai, 121 miles. Heavy cars, 6 hr. 45 min. (18 miles per hour); light cars, 8 hr. (15 miles per hour). Gundagai to Albury, 121 miles. Heavy cars, 7 hr. 30 min. (16 miles per hour); light cars, 8 hr. 40 min. (14 miles per hour). Albury to Euroa, 101 miles. Heavy cars, 7 hr. 15 min. (14 miles per hour); light cars, 7 hr. 50 min. (13 miles per hour). Euroa to Melbourne, 100 miles. Heavy cars, 6 hr. 15 min. (16 miles per hour); light cars, 7 hr. (14 miles per hour). The total run will thus be 572 miles.

Motor-Cars in War.

ACCORDING to Reuter, General Kuropatkin has acquired a new 20-h.p. automobile, with which he is enabled to rush at high speed from one place to another along the Russian line, which is twenty-five miles long. M. Ravoir, an automobile expert, who has reached Chefoo from Mukden, states that he spent three weeks with General Kuropatkin, who wished to secure twenty motor-cars specially constructed to carry ammunition speedily in case of emergency. These cars will only be used in winter, when the Manchurian roads are excellent. In view of the distances between various points at which the army is located we should have thought the value of the motor-car would have been recognised before now.

◆ ◆ ◆

Motor-'Buses.

MOTOR-'BUS services are evidently to be a success financially as they are from the point of view of public convenience. Previously we have referred to the profits of the Hastings service. Recently illustrated reference was made to the vehicles in the Eastbourne services, and now comes news that the Torquay Motor Omnibus Company is able to pay five per cent. dividend as the result of the first year of operation. The 'buses have provided better means of locomotion than hashi herto been known in the district, while the selected routes have been a recognised matter of public convenience. Mr. Fuller, the engineer of the company, is to be congratulated on the way in which the service has been run, and there is no doubt that the punctuality of the cars and the civility of the drivers are two essentials in such a service. From another part of England we have a complaint that these two features are absent from a motor-'bus service recently developed, and we would take this occasion to suggest to our erring friends that if they wish to emulate the financial prosperity of the Torquay Company, they will have to be as keen in these matters as are the directors of the Devonshire concern. New motor-'buses are to be put on the road at Torquay next season, and there is no doubt that the town will share in the general automobile revival that seems to be taking place in the west of England.

TWO meetings of the committee appointed to inquire into the use of duty-free alcohol for industrial purposes have been held this week.

ON page 844 Mr. Percy Richardson raises an important question with regard to the control of motors, upon which the views of readers are invited.

A NEW arrangement of the work of the officials of the Automobile Club has lately been made. Mr. J. W. Orde is now the secretary, Mr. W. Rees Jeffreys the head of the legal department, and Mr. Basil H. Joy the head of the technical department.

MESSRS. WEBSTER AND CO., County Motor Works, St. Albans, have taken over the premises occupied by the Ormonde Cycle and Motor Company, Limited, for many years in Wells-street, Oxford-street, London, W. The premises are well adapted for garage purposes, and will enable Messrs. Webster to greatly extend their already large connection. We understand the St. Albans business will still be retained, and motorists passing through the cathedral town will find the works well prepared for any trouble that may occur.

AT a meeting of the Highland District Committee of Perth County Council at Logierait, Sir Donald Currie has called attention to the necessity for stringent regulations applicable to motor-car traffic for the narrow portions of the roads in Glenlyon district, on which accidents have already occurred. It was agreed to take no action. A similar decision was made regarding a complaint by Sir Donald of the danger to motor-car traffic through the dilapidated condition of the protection wall of the Rannoch Road from Keltneyburn to Whitebridge.

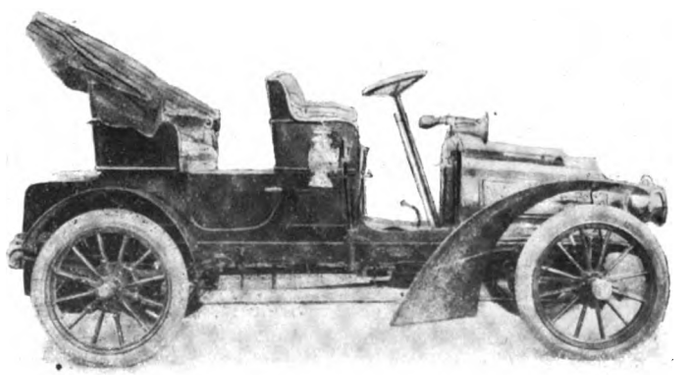
The Paris Motor-Car Exhibition.

Le Grand Palais, Paris. The Locale of the Exhibition.

THE seventh annual Salon d'Automobiles, which is to be officially inaugurated in Paris to-day (Friday), will remain open until Christmas night, during which time it will be visited by motorists and motor traders from all parts of the world. As was foreshadowed a year ago, the huge Grand Palais at the corner of the Champs Elysées and the Pont Alexandre III. has become too small for the annual display, the motor-boats and the machinery in motion having this year been relegated to the "Serres" or the Horticultural Palaces, which formed part of the 1900 Exhibition, and which are located close to the Seine. The Grand Palais itself has for about a fortnight been in the hands of a vast army of workmen, the results of whose labours are seen in the magnificent display now housed under the roof of the Grand Palais. As usual, the leading builders of motor-cars have vied with each other as to who shall have the best decorated stand, the result being that the general aspect is, if anything, more brilliant than ever. The Krieger stand, for instance, takes the form of an Egyptian temple, that of the Darracq Company represents an Arabian gateway, while that of the Richard-Brasier Company is surmounted by two striking paintings, one representing a car travelling at full speed, and the other a motor-boat on the Seine. The show is a veritable Babel of languages, the visitors emanating from all parts of the world. Great Britain and Ireland are well represented, and, in fact, to give the names of those from this country who are attending the Salon would mean the production of a directory of all the leading British motorists and motor traders. This week we are forced to content ourselves with a description of the exhibits of two or three well-known firms, but, in accordance with our usual practice, a full account of the novelties and 1905 models of the leading concerns, based on personal observation, will be given in the next issue of the *Journal*.



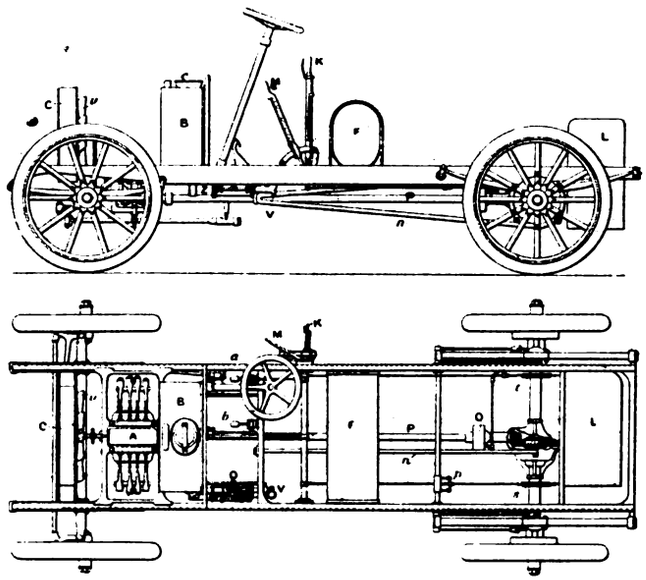


Fig. 1.—The New Serpollet 9-h.p. Steam Car.

The Gardner-Serpollet Co.'s principal exhibit is a new 9 h.p. steam car which outwardly bears a close resemblance to a petrol vehicle. As will be seen from the plan and elevation (Figs. 2 & 3), the engine and fuel and water feeding arrangements are located in the fore part of the frame under a bonnet, the raising of which gives ready access to the various parts. The engine, which comprises four horizontal cylinders—two on each side of the crank-shaft—is now placed across the frame, the power being conveyed to the rear axle by a cardan shaft and bevel gear, in place of the single chain drive of last year. The old condenser and its piping have been replaced by a radiator placed in the front opening of the bonnet, a strong current of air being drawn through the same by means of a fan driven by a chain off the engine shaft. The steam generator is enclosed in a chest at the rear, and is hardly noticeable; its weight and volume is much smaller than hitherto, these advantages being a result of an improvement in the fuel-burning arrangements. Ordinary petroleum is, of course, used as fuel, and provision is made whereby the pilot burner may be kept going for days together on a very low consumption and without danger to the tubes of the generator. The fuel and water feed to the generator is controlled by pumps Q (Fig. 3), actuated by a small steam pump controlled in turn by a small lever on the steering column. Fig. 1 illustrates the four-seated side-entrance double phaeton, which, complete with fuel and water ready for the road, weighs under 17 cwt. One advantage of placing the engine in front is that the load is now about equally divided on the front and rear axles, the weight on the hind wheels being approximately 9 cwt. A two-seated car on similar lines is also being made, the *chassis*

Digitized by Google

being adapted to receive different types of bodies, a popular type being an entirely closed one, driven from inside, and intended for the use of doctors and commercial travellers. Examples of the Serpollet 15-h.p., 40-h.p. and 60-h.p. steam cars are also to be seen at this stand, these, together with the new 9-h.p. vehicle illustrated herewith, forming the four types the

Figs. 2 and 3.—Elevation and Plan of new Serpollet 9-h.p. Steam Car.

A Engine.
B Water tank.
C Condenser.
F Fuel tank.

L Generator.
M Engine reversing lever.
P Cardan shaft.

Company is building for the 1905 season. All lovers of steam cars will be pleased to see that M. Serpollet is determined to keep on improving his system. Each year has marked an advance, and the simplification of the working now accomplished in the new 9-h.p. car is one of the most important so far recorded.

The Buchet Company, of Levallois-Perret, gained a reputation at an early period in the development of automobile motors, as builders of extremely light and powerful motors, of which they have furnished quite a number for aeronautical purposes. They are also the originators of the Buchet "culasse," a cylinder head into which the valves open directly from above. Lately they have also brought out

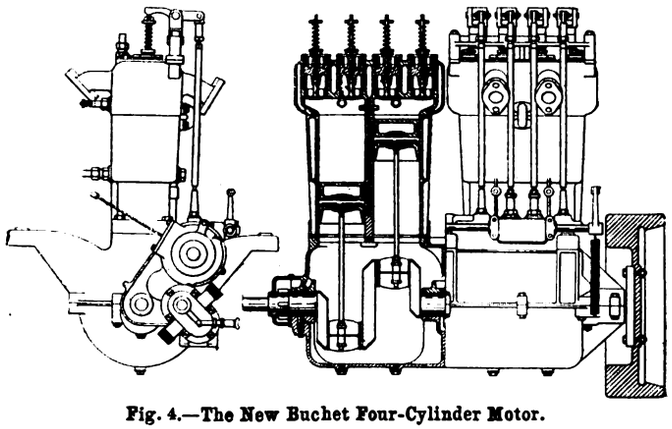

Fig. 4.—The New Buchet Four-Cylinder Motor.

a motor with mechanically-operated inlet and exhaust valves in a chamber at the side of the cylinders, but still retaining the old type with valves in the head, the latest form of which is illustrated in Fig. 4. It will be noticed that the cylinder head is cast separately and bolted to the cylinder casting; each part has a separate water jacket, the two jackets being placed in communication by a short outside tube in the form of a U. The waterspace in the heads entirely surrounds the valves, and in order to obtain room for large valves, the heads are bulged out beyond the cylinder wall at the sides. The valves are arranged in cages and can be removed as a whole. It will be noticed that the part of the stem near the head is very large in diameter, to guard against the head of the valve breaking off and dropping into the cylinder. Besides, if the inlet valves should break, they would apparently be caught between an internal flange and the sparking plug end, and could not drop on the piston. The valves are all interchangeable and mechanically-operated by means of rocking levers, or tappets, and long push rods extending up one side of the cylinders. The engine speed is controlled by varying the lift of the inlet valve by means of mechanism associated with the cam gear, which is normally held in the position of small lift by a spring, one end of which is secured to the crank case. The crankshaft has two outer and one intermediate bearings, all of the ring self-oiling type. The cam gears, cams and ignition contact maker are enclosed in separate cases at the end of the crank chamber, and the water-circulating pump forms an integral part of the engine and is driven by gears direct. The

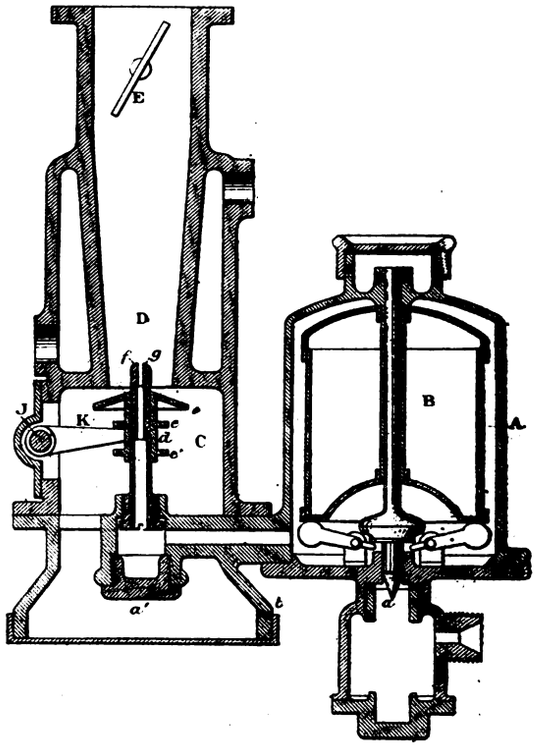

Fig. 5.—Section of Gobron-Brillie Automatic Carburettor.

motors are made in two sizes, 16 and 24-h.p., and also as two-cylinder motors of half these powers. The speed varies from 1,000 to 1,200 revolutions per min. The Buchet Company are also making a range of air and water-cooled single-cylinder motors varying in power from 2¼-h.p. to 5-h.p.

For the 1905 season the Société des Automobiles Gobron-Brillié is confining its attention to two sizes of cars, viz., 25 and 35-h.p. In both the frame is of pressed steel construction with a shield extending from the forward end well to the rear, to protect the engine and clutch from mud and dirt. The familiar Gobron-Brillié motor, which has two pistons in each of the four cylinders, is retained, the explosions taking place in a central combustion chamber. The four cylinders are cast in two pairs: the valves are all mechanically operated and interchangeable, the inlets being on the opposite side to the exhaust. Both accumulator and high-tension magneto ignition are employed, these being so arranged that either may be brought into use by means of a switch. The pump, magneto, and carburettor are all mounted directly on the engine. The water circulation is maintained by a gear-driven pump, and a ribbed radiator set in a frame forming the water tank. A new automatic carburettor forms one of the features of the latest

Digitized by Google

Gobron-Brillié cars. From the sectional view of the device given in Fig. 5 it will be seen that it consists of a float-feed chamber A and float B, actuating the usual form of needle valve, admitting petrol to the jet *f*. The fuel passes through a gauze filter upon arrival beneath the chamber *a*, which is formed with a catch pit, into the bottom of which all impurities can sink. Another catch pit *a'*, of similar form, is seen beneath the jet. Air reaches the mixing chamber D through the gauze at the bottom of the chamber *b*. Around the spray jet tube is placed a sliding mushroom valve, opposed to the narrow opening at the bottom of the mixing chamber D, and this valve is connected up to the spindle of the throttle valve E by means of the arm K, the spindle J, and an external arm, rod, and cam device. The throttle valve E is controlled by the engine governor, and the mushroom valve C moves in such proportion therewith as is permitted by the shape of the external cam. The shape, angle, and movement of the valve C are so designed and arranged that for every variation in the piston speed of the engine such suction is produced over the jet that the delivery of petrol is infinitesimally varied, so as to obtain perfectly proportionate carburation. The mixing chamber D is provided with a

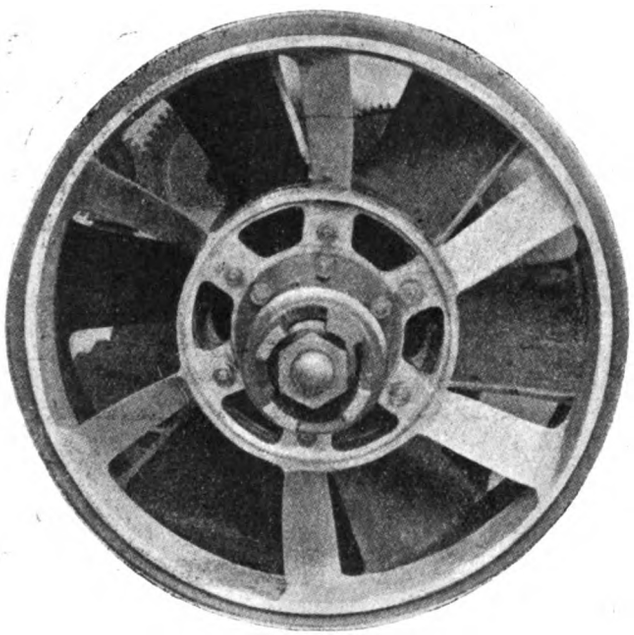

Fig. 7.—The Gobron-Brillie Double Clutch.

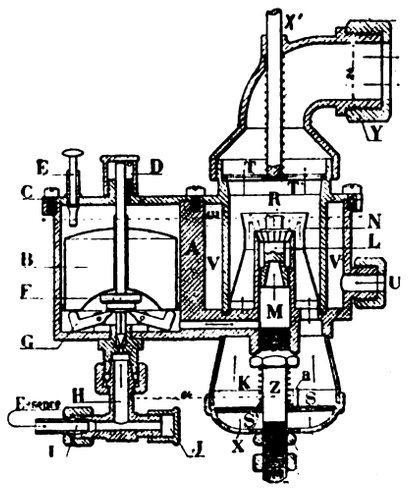
jacket through which hot water is caused to circulate. Once adjusted, the carburettor is permanently set, and no variation is possible. This type of carburettor was, we understand, used on the Gobron-Brillié cars which have competed in this year's races in France and Belgium. The clutch (Fig. 7) is of new design, being practically in duplicate, there being two cones. The smaller one, which is metal-to-metal, engages first, followed by the engagement of the large one, the cone of which is leather-faced. Both clutches are controlled by the same pedal; the advantage of the arrangement is that the engine is put into gear without shock, while, to further reduce any strain on the gear-box, a universal joint is introduced between the latter and the clutch. Four speeds forward and a reverse are provided, with a direct drive to the countershaft on top speed. The gear-box and countershaft are so arranged that they can be detached from the *chassis* without the body having to be removed, and can be readily replaced in their proper position. The wheel base of the cars is of such a length as to permit of side-entrance bodies being fitted, the cars exhibited including several excellent specimens of the motor-carriage building art.

THE Herald Motor Manufacturing Company, Limited, has been registered with a capital of £100. The first directors are Messrs. T. M. C. de Bingham and P. A. E. Wood.



MOTOR CYCLING NEWS.

DURING the last summer Mr. F. P. Driver, of West Hampstead, successfully completed a 900 mile tour on his Phœnix Trimo. He took the machine over the worst hills in Cumberland and succeeded in riding up Kirkstone Pass from the Penrith side. The pass rises 1,000 feet in 2½ miles and 800 feet in the last mile and a half, the gradients in many parts being one in eight.

AT the annual dinner of the Auto-Cycle Club last week Colonel Holden presided. Mr. S. F. Edge, in proposing the toast of the evening, reminded those present of the existence of the Motor Cycling Club, which was first in the field. He paid a tribute to the work of the Auto-Cycle Club, and, after the presentation of prizes to the winners of the various competitions during the year, it was announced that Mr. Edge had offered 100 gs. towards a fund for the promotion of a motor-cycle Gordon Bennett contest.

THE first long-distance motor-cycling race held in the Commonwealth was successfully carried out in Western Australia on October 8th. The race was from Beverley to Perth, a distance of 116 miles. The number of competitors was small, but it comprised the leading motor-cyclists in the district. The winner was F. Mallabone, on a 2-h.p. Minerva motor-bicycle, who received 30 minutes start, and covered the 116 miles of indifferent road in 5 hrs. 41 min. 30 sec., which gives an average speed of nearly 20 miles an hour. D. Jewell (20 min.) ran second on a 2¼-h.p. machine, his time being 5 hrs. 36 min. 14 sec. R. Ward (30 min.) finished third in 6 hrs. 58 min. 35 sec. on a 2-h.p. machine.

FOR the 1905 season a new form of the Longuemare carburettor for the engines of motor-cycles has been brought out in which the greatest change from last season's type is to be seen in the vaporising compartment. The conical air adapter and the spraying nipple with varying numbers of slits is still retained. The shutter, which made the apparatus semi-automatic, has, however, been discarded, and a spring suction air inlet S substituted; it will be readily understood that the faster the engine runs, the

further the disc S will be lifted off its seat. There is no additional air inlet provided above the spray, all the air entering at S and passing the spray at varying speeds, according to the lift allowed by the spring K. The throttle is quite new, and now consists of a rotating disc T, held to its seat by a spring and rotated by the rod X'. Over the rod is screwed the cap through which the rod X', works in a guide. The union nut Y is connected up to the admission pipe in the usual way.

MR. E. A. LIVET, who is well known in the motor trade, and who at one time was responsible for a Kentish motor service, intends to startle the amusement-seeking people of the metropolis by shortly appearing at a West-end music-hall and turning a complete somersault with a motor-car of about 5-h.p.

THE "SIMPLEX" ELECTRIC IGNITION.

—♦—

WE are now able to publish details of the new system of electric ignition for petrol motors, reference to which was made in the *Journal* of the 15th October. The rights in the arrangement, which is due to Mr. A. McLeod, of Fulham Road, S.W., have since been acquired by the Kennedy Motor Company, Limited, of Cathcart, Glasgow, which is about to put the ignition on the market. As has already been stated, the system may be briefly described as a cross between the jump spark of the high-tension ignition with coil and accumulators and the make and break of the magnets. To provide the spark required at the proper instant the circuit includes two breaks, one of which is the usual contact maker on the half-time shaft, and is normally open, while the other is inside the combustion chamber and is normally closed. When the circuit is closed at the contact maker, the current energises an electromagnet included in the circuit, and by means of the consequent attraction against the force of a spring of a soft iron armature attached to one of the contact pieces of the internal break, the latter is opened and the spark due to the so-called "extra current" of the induction circuit is produced and ignites the charge, a series of such sparks taking place during the time that the external break is closed.

Referring to the accompanying illustrations Fig. 3 is a plan of the apparatus, in which the ignition circuit and external

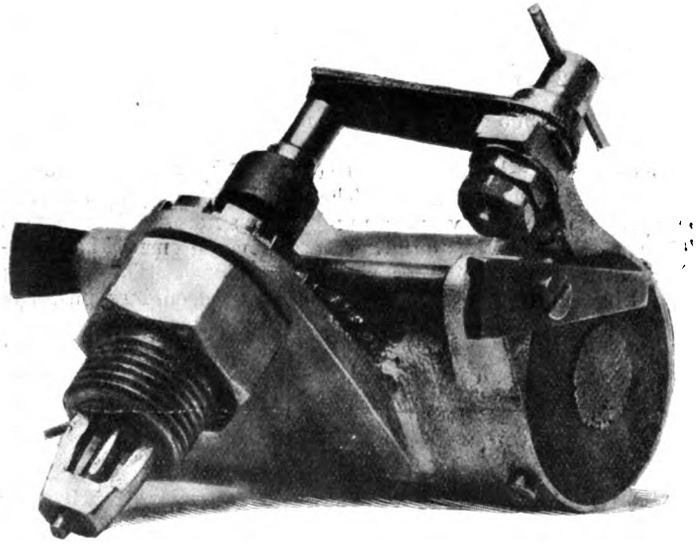

Fig. 1.—General View of Electromagnet and Plug.

break are shown diagrammatically; Fig. 2 is an elevation; Fig. 4 sectional details showing the arrangement of the sparking plug which forms the internal break; and Fig. 5 a diagram showing an arrangement of the contact maker or external break for a four-cylinder engine. The circuit includes a battery A, consisting usually of four two-volt cells, one terminal of which is in connection with one end of a small coil C, and the other earthed through a contact maker B, the plug F being also earthed. The other end of the coil, which encircles a soft iron core C^1, is connected by the arm D with the platinum-pointed spring piece D^1, which is clamped between the arm D and a bracket E, fixed to, but insulated from the iron casing E^1, enclosing the coil, and is backed by a second spring D^2, which acts as a yielding stop to limit the travel of the movable electrode H. The ignition plug F, clamped to a projecting part of the casing E^1, by means of the nut F^1, is formed for screwing into the explosion chamber in the usual way, and has a central plug G (Fig. 4), of insulating material through an axial hole in which passes a rod H, of hardened steel. On the one end of the rod is adjustably fixed a contact piece terminating in a steel ball H^1, which abuts against the platinum point of the spring D^1, and is urged forward by it so as normally to hold the other end of the rod H in contact with the bridge piece K^1, formed integrally with the body of the ignition plug. The springs D^1, D^2 are so pivoted by a set screw D^3 between the arm D and the bracket E that they may be turned to one side and the sparking electrode H instantly removed or replaced when desired. The armature of the electromagnet C consists of a soft iron or steel rod L journalled in the casing E^1 and having fixed at right angles to its ends and in the same plane with each other and the rod L two bars or fingers L^1 of similar material. These fingers, which are long enough to reach beyond the centre of the iron core C^1 and are formed with balancing extensions L^2, are

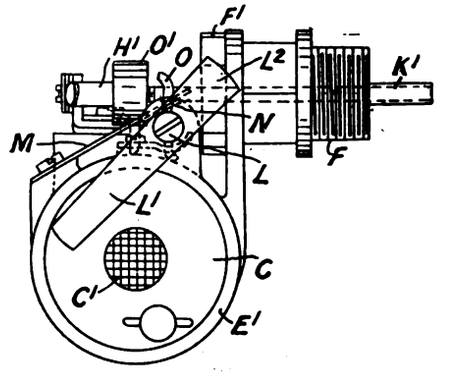

Fig. 2.—End Elevation.

normally held displaced to one side of the core by means of a spring M fixed on the coil casing E^1. The spring M engages with a reaction piece N fixed on the rod L, in a slot L^2, in which is pivotally mounted a pin O, one end of which projects upwards behind a collar O^1, made of insulating material and fixed on the rod H. The other end of the pin O travels in a cam slot O^2, formed in the casing E^1. The slot is shaped so as to constrain the point of the pin O which encounters the collar O^1 to travel in a substantially rhomboidal path during the movement of the armature of the electromagnet, with the result that when the armature is attracted a positive rotation is imparted to the collar O^1,

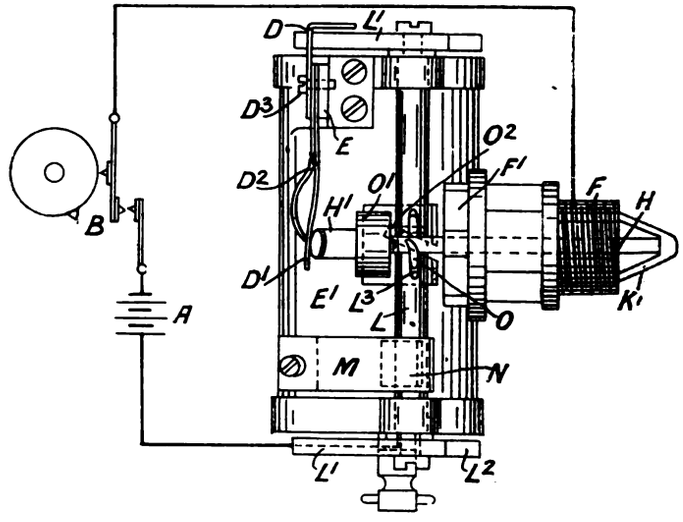

Fig. 3.—Plan.

and therefore to the rod H, the object being to equalise any wear on the inner end of the rod. The eccentric engagement of the pin O with the collar O^1 causes the latter, and with it the electrode H, to turn through a small angle each time the electromagnet is energised, the regular wear of the sparking surface thus secured not only increasing the life of the electrodes but also the certainty of their action. The arrangement of the spring M and reaction piece N is such that the armature is able to oscillate on either side of its normal position of rest, while the balancing of the armature renders it practically unaffected by

Digitized by Google

engine vibrations, and therefore minimises the chance of a mis-fire resulting from such vibration.

Passing now to the action of the apparatus, when the contact maker B is open the sparking electrodes H, K are held in contact by the spring D^1, but as soon as contact is made at B the electromagnet is energised, the fingers L^1 of the armature are attracted towards the centre of the core C^1, thereby turning the rod L in its bearings so that the pin O pressing against the collar O^1 forces the electrode H backwards against the spring D^1 and causes a break in the circuit at the inner end of the plug, resulting in an enormous spark at that point, due to the

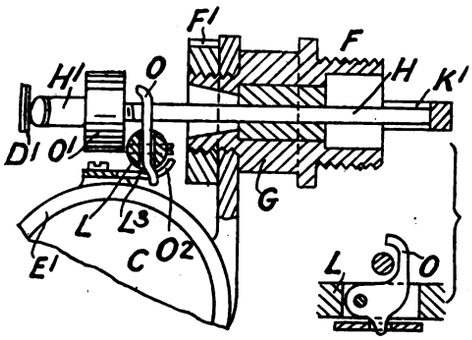

Fig. 4.—Sectional View of Plug.

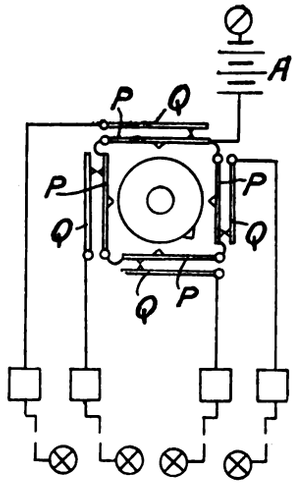
so-called "extra current." The electromagnet again becoming de-energised the spring M returns the armature to its normal or unattracted position and the spring D^1 tends to close, and if there has been no ignition of the charge in the cylinder, will close the break at the electrodes H, K and the electromagnet will again become energised if the contact is still made at B. The time of contact at B can be varied within wide limits, but even the least time of contact obtainable by mechanical means is long enough to produce a series of "breaks" and "makes," and therefore a series of sparks, at the electrodes H, K. As soon, however, as the combustible mixture has been ignited, the resulting pressure in the cylinder forces the rod H outwards against the reaction of the spring D and holds the electrodes H, K out of contact long enough to keep the circuit broken at H, K until it is again broken at the contact maker B. In the case of two, three, or four cylinder motors, each cylinder is provided with its own coil and plug, worked off the one battery, through a special contact maker, that for a four-cylinder engine being shown diagrammatically in Fig. 4. One element P of each of the contacts is connected to one of the poles of the battery A, and these elements are arranged to be successively displaced by a moving part of the engine so as to be brought into contact with its fellow element Q, each of which is connected to one end of its corresponding coil. There is thus no high tension wire, the only wires in a four cylinder engine being a short one earthing one terminal of the battery, another short one from the terminal of the accumulator to the contact maker, and one from each of the contacts to the coils.



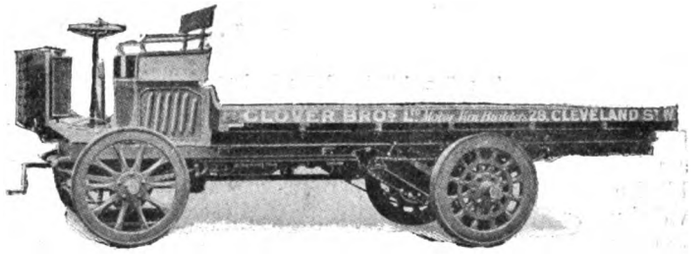


Fig. 5.—Diagram of Four-cylinder Contact Maker and Connections.

The size and power of the spark, which has to be seen to be realised, is such that the complete charge in the cylinder is fired much quicker than usual, resulting in a more rapid explosion; while, apart from this, one of the great advantages of the system is its ability to furnish a series of sparks at low as well as at high engine speeds. There is no escape of explosive mixture at the movable electrode, which is a nice fit and has a $\frac{3}{4}$ in. bearing in the body of the plug. The electrode is so made that it can easily be adjusted to allow for any wear, while it can be renewed at the cost of a few pence. Oil or sooty deposits on the inner ends of the plug do not appear to have any effect on its action, nor does the proximity of the coil to the explosion engine cause it to be adversely affected by the heat, it consisting of seven layers of 10 gauge wire well insulated. The device is exceedingly compact, as will be seen from the fact that the illustrations given herewith show it practically to full size.

THE GLOVER PETROL MOTOR LORRY.

MESSRS. GLOVER BROS., LIMITED, an old-established firm of van builders, have for some time past been devoting attention to the question of motor vehicles for commercial purposes, and have recently introduced the petrol lorry illustrated herewith. The vehicle is designed to carry an ordinary pair-horse load of forty to fifty cwts., with a maximum of three tons. The frame is of armoured wood, with steel connections; the engine, which is located under the driver's seat, is a 12 to 14 h.p. double-cylinder Aster with mechanically operated inlet valves. The power is transmitted through a leather-faced cone clutch to a gear-box giving three speeds forward and a reverse, with a direct drive on the top speed, and thence by bevel gear to a differential countershaft, side chains connecting the latter with the rear road wheels. The differential counter shaft is entirely separate from the gear-box and connected thereto by a flexible joint, allowing for "play" in the *chassis* when running over rough or uneven roads. Both front and rear

axles are of solid forged mild steel. The rear axle is connected to differential shaft by means of solid hinged stay rods, which transmit the drive of the wheels to the *chassis* and serve to take up the wear of the chains by means of right and left handed threads in the usual manner. Three brakes are provided, while the steering gear is of the irreversible type; the road wheels are of artillery pattern fitted with wide steel tyres. The steering gear, brakes, engine, etc., are all controlled from the driver's seat, which is placed well forward over the front axle, giving a large space for load and decreasing the wheel base. The new vehicle appears to be of sound construction; special attention has been paid to the matter of rendering the engine and transmission gear readily accessible; the lorry is geared to a top speed of about twelve miles per hour, and Messrs. Glover inform us that loaded with three tons it has successfully climbed Haverstock Hill, a stiff climb in North-West London.

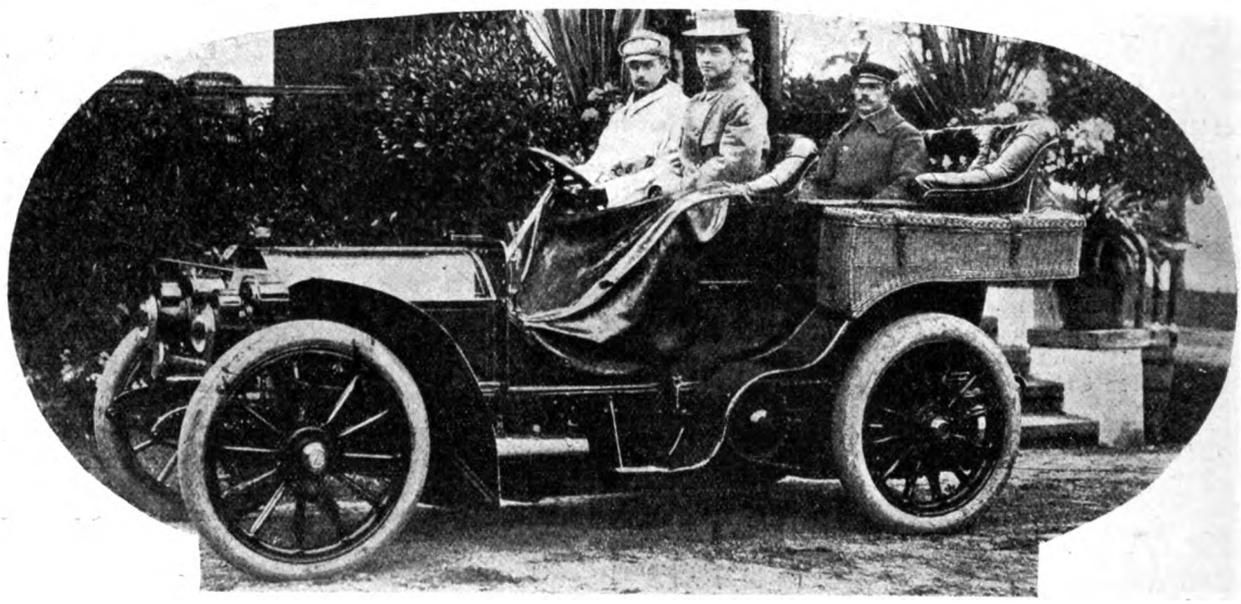
THE USE OF THE ACCELERATOR. FOOT *v.* HAND CONTROL.



By Percy Richardson.

I WAS very interested to read the letter from your correspondent, Mr. R. T. Priest, with reference to controlling the speed of a car by the feet, as this is a question that I have been devoting attention to for some time. I agree with your correspondent that the arrangement as used on the Fiat car, of which I have had some experience, is a distinct advantage over the hand control as is generally fitted either on the steering pillar or steering wheel of the majority of cars, as this certainly does leave the hands perfectly free for steering, changing speed and applying the hand brake, which is a great boon when driving either on greasy roads, through fog, or in wet weather. The disadvantages that I have found with the system of control referred to by your correspondent are, that in the first case it necessitates three foot levers, and in the second case, the manner in which the foot lever actuating the throttle on the engine is arranged is such that, when driving over a bumpy road, it is rather inclined to vary the pressure of the foot on the pedal, and so, inadvertently, alter the throttling. My objection in the first case to the use of three foot levers is, that I consider it is a mistake to give the driver of a car more levers to work with his feet than the number of these extremities that he is provided with; as though the majority of drivers are very expert in changing their feet over from one pedal to another, it would be much more convenient if there was no necessity for doing this, and, moreover, would obviate the likelihood of accidents, which to my knowledge have occurred in several cases through the accelerator pedal being pressed down in cases of emergency instead of the brake pedal. The consequence has been that, instead of the speed of the car being checked as desired by the driver, the opposite result has happened.

Although I am not prepared to divulge at the present moment the manner in which it is carried out, I may say that, in the "Brotherhood" car, in the design and construction of which I have been occupied during the last twelve months, I have perfected a method of control for the engine that does away entirely with all hand levers, and only necessitates two foot levers. This, besides being much more convenient than the ordinary system, or the arrangement previously mentioned, is arranged so that it allows the driver to obtain a much finer graduation of the speed of the engine, and also to vary the same without any trouble more continuously, so as to accommodate the speed of the car to all circumstances, and at the same time it cannot be affected by any vibration or shocks caused by the unevenness of the road affecting the pressure of the foot on the pedal. I have been testing the arrangement for some time under all the varying conditions of driving, and I am pleased to report that I find the advantages of this arrangement very considerable indeed, as it enables a person driving a car to take much greater advantage of the flexibility of the engine than any other arrangement I have yet met with. Furthermore, I find that it is not at all trying to drive under the worst circumstances, an example of which I had only a few days ago, when I drove to Leicestershire, a distance of over a hundred miles, through a dense fog the whole distance, in which it was not possible to see more than thirty yards ahead the whole way. The roads were exceedingly greasy, and, though I had no non-skids whatever fitted to the car, I was able to do the journey without the slightest sign of a skid, and maintained a very good average speed without running any risks, and at the end of the journey I did not feel the usual strain one does when driving a long distance under such conditions.

Personally, my own idea on the arrangement for the control of motor-cars is that the same should be arranged in the simplest possible and also in the most convenient manner, and in consequence I think the fewer the control levers fitted the better. It is apparent from the arrangements for the control of some cars, that those responsible for the design have overlooked the fact that a human being is only possessed of one pair of hands and one pair of feet, for on some of the cars one sees there are so many levers provided that it really looks as though it would take two persons to properly handle the car. Peculiarly enough, too, these are generally fitted to small, low-powered cars, whereas the higher-powered cars are usually more simple.

I may also say, in conclusion, that the arrangement I have designed is so arranged as to enable any ordinary motorist or inexperienced driver of a car to obtain just as good results as an expert could. I had a striking proof of this only a short time ago, when I invited a friend to drive the car up a hill upon which the vehicle had been continually tested, and though he has only been a motorist for a matter of about six months, and had never handled a four-cylinder car before, his speed up the hill (which is about a mile long), was only a fraction of a second under the best time the car had ever made before on the same hill.

The Grand Duke of Mecklenburg-Schwerin, Patron of the Mid-European Motor-Car Union, at the wheel of his Mercedes Car.

Some of the omnibus owners have been summoning certain drivers of the electric tramcars of the London County Council for exceeding the speed limit.

THE "CORONET" PETROL CARS.

THE CORONET MOTOR COMPANY, LIMITED, of Coventry, have lately brought out two new types of double-cylinder petrol cars of 10-12-b.h.p. and 15-17-b.h.p. respectively. Each cylinder, together with its water jacket, is cast separately. The bore of the 10-12-b.h.p. engine is 3¾ inch and the stroke 4⅜ inch, while the dimensions of the 15-17-b.h.p. motor are 4 3-8 inch by 5 1-8 inch. The pistons are of good length and are fitted with three eccentric rings. The crank shaft has a bearing between each throw of the crank. The valves

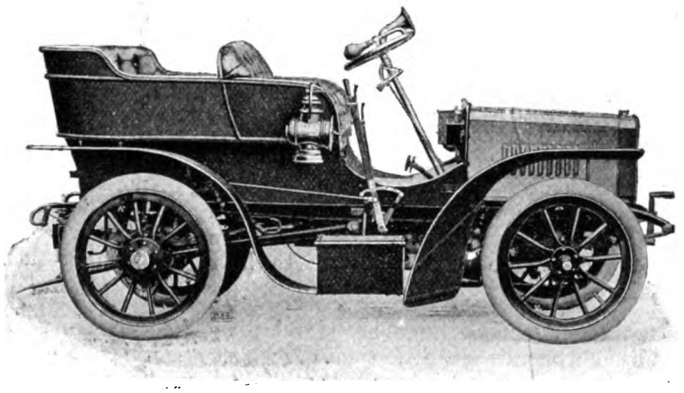

Fig. 1.—General View of Coronet 10-12-h.p. Car.

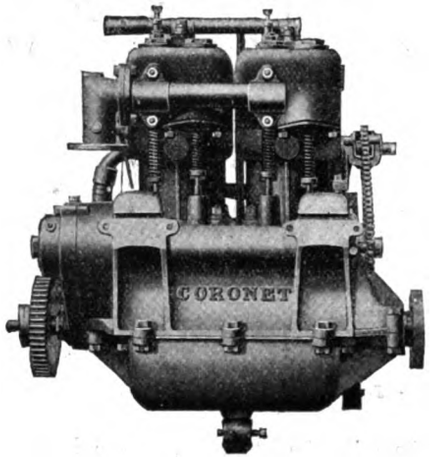

Fig. 2.—General View of Double-Cylinder Engine.

are of large diameter and mechanically operated by one cam shaft, which is supported by a central bearing, and, together with its gear wheels and the governor, runs continuously in oil in a dust proof case. Two large inspection plates are fitted in the lower half of the crank case. The normal speed of the engine is 1,100 revolutions per minute. The ignition is on the high-tension system, with accumulator and coil, while the water cooling is maintained by a gilled-type radiator and tank, and a gear-driven centrifugal pump fixed to the front of the engine. The power from the motor is transmitted to the gear box through an internal leather-faced clutch entirely free from end thrust either to the motor or gear box, whether the clutch is "in" or "out," a universal joint being arranged between the gear box and clutch. The gear, which is one of the company's own design, gives three speeds forward and one reverse, all controlled by one lever. The top speed is a direct drive with all the gear wheels out of mesh. Fig. 4 shows the gear box with the upper half removed, exposing the gears, which are in second speed. The clutch shaft is connected up to the square shaft A, on which is mounted a sliding sleeve B, carrying the two spur gear wheels C and D, which are used for the reverse, first and second speeds, in the usual way, the reverse being obtained when the wheel C engages with the pinion E, to which is coupled on the same shaft the pinion F, gearing into the wheel G on the second shaft; the pinion H, which is solid with the second shaft, now turns the wheel I, which carries jaw clutches K, engaging with similar clutches L on the shaft J, to which is coupled the cardan shaft. The first speed is obtained by moving the wheel C into gear with G, turning the second shaft without the introduction of pinions E and F, and consequently in the opposite direction, thence through wheels H and I, as before. The second speed is obtained when wheel D is moved into gear with wheel M, turning the second shaft as before, but faster in proportion to the number of teeth on wheels C and G, and D and M. The top speed or direct drive is obtained by engaging the jaw clutches N on the sleeve B with similar jaws O on the shaft J, and when these are engaged the wheel I, which has been in use for the reverse, first and second speeds, moves towards the sleeve B, allowing the jaw clutches K on the wheel I and L on the shaft J to disengage and be perfectly clear of each other; the shaft A now drives the cardan shaft J freely through the wheel I, which, together with the second shaft, is idle. It should be mentioned, however, that on the top speed or direct drive the wheel I is not moved sufficiently to disengage it and the pinion H; it is just in gear, and the moment the control lever is moved to change to the next speed slower, the jaws K and L immediately engage each

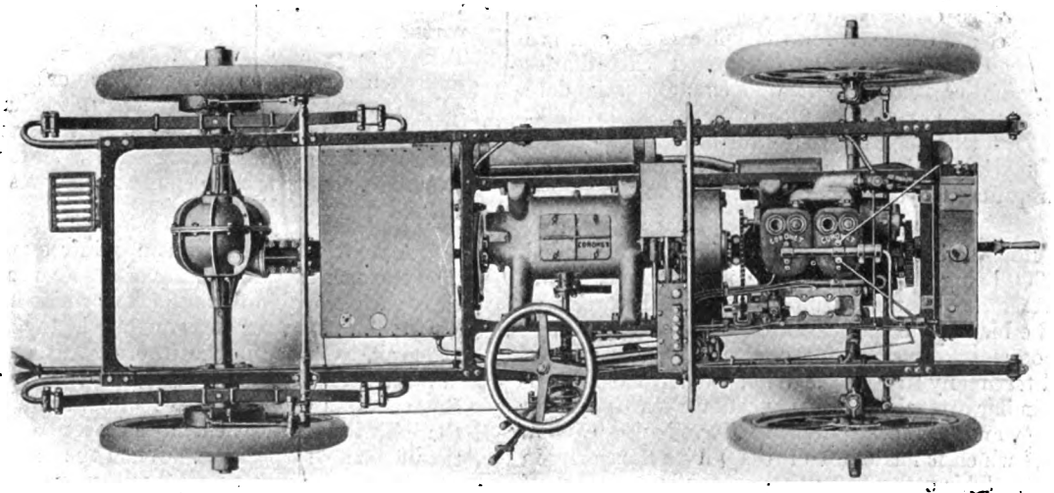

Fig. 3.—Plan of Coronet 10-12-h.p. Car.

Digitized by Google

other and set the second shaft and its wheels in motion before the wheels D and M engage. The sliding gear B is moved to and fro by the fork P, and the wheel I by the fork Q, the whole gear being worked through the pinion R outside the gear box. The transmission from gear box to the road wheels is by cardan shaft and live axle. The road wheels are mounted on a casing

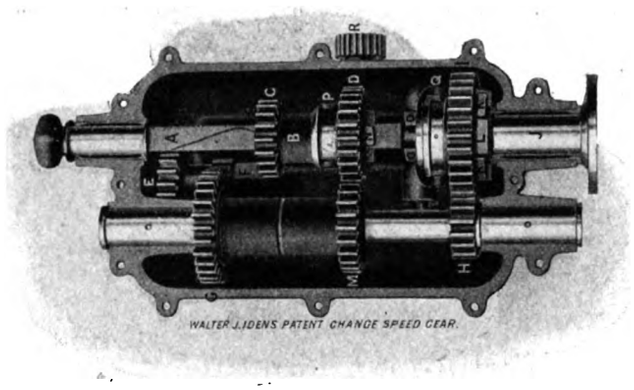

Fig. 4.—The Coronet Change Speed Gear.

surrounding the axle, the latter driving the hubs of the wheels through steel star clutches firmly fixed to the driving-shaft; by this method there is claimed to be no possibility of the road wheels spreading, the weight of the car and the road shocks being taken not by the axle but by the strong outer casing. Three brakes are fitted, all being of the same size. The steering gear is the Coronet Company's special irreversible type. Accleration is by pedal; the throttle is regulated by a neat lever and rack under the steering wheel; this rack also carries the lever controlling the ignition and a lever regulating the air supply to the carburettor, which can be opened wide when the car is travelling fast, so reducing the petrol consumption to a minimum. Best plain bearings are fitted throughout, the only ball bearings being those fitted to the clutch and steering swivels. We have had a long run on one of the Coronet cars and found it an excellent hill climber and capable of attaining a speed on the level of forty miles per hour. It should prove a reliable touring vehicle, being built to stand the strain of rough and hilly roads and having a great reserve of power. We may add that the Farman Automobile Company, Limited, have been appointed London agents for the Coronet cars.

MESSRS. CHARLES LETTS' series of Diaries for 1905, are conspicuous among such annual reminders of the flight of time by reason of the insurance coupons inserted within their covers. The scribbling diaries are designed for the office desk, and are with one, two, three or seven days to a page. Pocket diaries are another speciality of the firm, as well as automatic date calendars. Clearness of type, excellence of paper, and intelligent arrangement are three characteristics of the diaries of this firm, whose combination of insurance coupons and self-opening tablets has given quite a new interest and value to such publications.

"WHO'S WHO" for 1905 comes with considerably extended pages, nearly 2,000 being contained in the new volume. One feature of the recreations of those who are accounted worthy to be included in the biographies published therein is the increased reference to motoring. Just as, at one time, the advent of cycling received testimony in "Who's Who," so automobilism is now attracting similar attention. In connection with the larger volume, Messrs. A. and C. Black, publishers, have issued "Who's Who Year Book," which is made up of the tables formerly in the larger volume. This contains much general information of interest, and the two books together will be found on many a bookshelf. Accuracy and completeness are characteristics of the volume.

SOME USEFUL NOTES.

ALWAYS see that your spare parts—especially the valves—are of the proper size for your engine, so that there may be no annoying delay if they are suddenly called into requisition.

◆ ◆ ◆

SOME motorists, when adjusting their chains, do not seem to realise that there is a correct position for the shackles on the back scroll. The top of these side-plates, or shackles, should always be leaning away from the hollow of the scroll.

◆ ◆ ◆

INLET valves do not get nearly as hot, and consequently do not expand as much as exhaust valves. For this reason less clearance should be allowed between the stems and push-rods of mechanically-operated inlet valves than would be allowed between the stems and push-rods of exhaust valves.

◆ ◆ ◆

INASMUCH as the springs on mechanically-operated inlet valves are usually weaker than on the exhaust valves, the wear on the parts which move them will not be so great. Another reason why the wear is less is that there is no pressure on the inlet valves at the instant when they are lifted, while the exhaust valves may have forty or more pounds pressure to the square inch on them at this moment.

◆ ◆ ◆

A PETROL motor does not develop its full power until it has been in operation a little time. When started the parts of the engine are cold, the cooling water is cold, the lubricating oil is more or less stiffened, a slight gumming of the cylinder walls and valves being quite common in cold weather until all parts have been heated. After a few minutes these factors disappear, and the motor resumes its wonted power, unless something else is amiss.

◆ ◆ ◆

ACCUMULATOR terminals should always be kept scrupulously free from corrosion, otherwise they will gradually become "eaten away" to such an extent that a slight extra jolt on the road will suffice to break them off, and it may then be a matter of great difficulty to effect even a temporary connection. After being thoroughly cleaned and polished, the terminals may be fairly well protected from the action of the acid by a coating of vaseline.

◆ ◆ ◆

IT occasionally happens that the stem of an exhaust-valve is slightly longer than it should be, so that the valve is prevented from closing properly. The spare exhaust-valve, which ought always to be carried, should be examined for this defect (best done by placing the valve in position and seeing whether, when it is closed, there is the usual clearance between the end of the stem and the tappet), and if found too long should be filed off. This is a process which is better done at home than at the roadside.

◆ ◆ ◆

IF necessity occasions the taking down of an engine, carefully watch the parts. If the manufacturer has not marked the various parts for their respective places, the motorist himself should do so. Take the case of valves. Exhaust valves will not always interchange, and if one, at some time or other, has been ground in a little more than the one next to it, it is hardly likely to suit that cylinder. Apart from the fact that the seatings will not agree, there is naturally a slight difference in the length of the stem, which is enough, sometimes, to spoil the compression through the valve not seating properly.

◆ ◆ ◆

A MOST tantalizing, but not infrequent, cause of puzzling intermittence in the running of a petrol motor is a floating particle, such as a thin flake of solder which has been detached from the carburettor, or has entered the float chamber from the tank. Carried in the intermittent current of the liquid it may suddenly become lodged so as to cover the capillary duct to the nozzle, preventing all egress of petrol. When the motor stops the petrol in the float chamber ceases to be stirred, and the particle finds a new position. When the motor is started again it is not in the way, but presently it returns and stops the motor again. Should engine troubles be experienced the float chamber of the carburettor may therefore be included in the parts to be inspected.

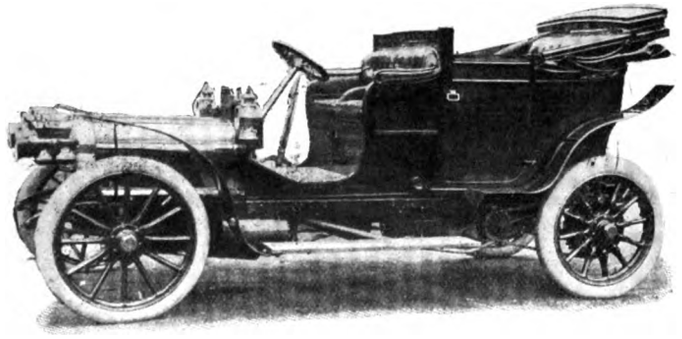
HERE AND THERE.

THE Duke of Oporto, brother of the King of Portugal, has just acquired a 16-h.p. Fiat car.

SIR SAVILE CROSSLEY, M.P., has received his 15–20-h.p. Brooke car. It has a very wide side entrance.

A MOTOR-CAR club is being formed for Sussex. The initial meeting will be held at Brighton on the 12th prox.

A PROJECT is under consideration to construct a cement road 26 ft. wide between Arcachon and Biarritz, a distance of about 80 miles.



THE Herefordshire Automobile Club have collected £50 locally towards the expenses incurred by them in entertaining the Reliability Trials of the A.C.S.B.I.

ON Wednesday last the students' section of the Institution of Civil Engineers paid a visit of inspection to the motor-car works at Acton of Messrs. D. Napier and Sons.

THE Beaufort Motor Company have sent out two Beaufort cars to their agent in Bombay. The vehicles have been entered for competition in the Delhi–Bombay reliability trials.

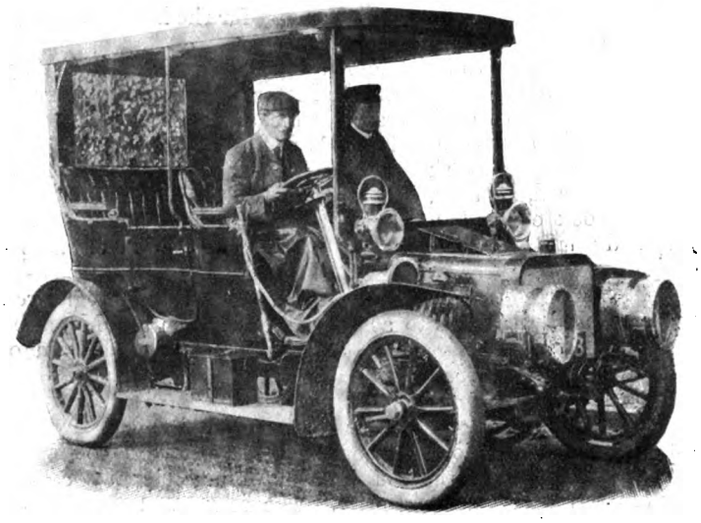
THE General Electric Company, Limited, have a neat side or head lantern for use on motor-cars. This can be mounted on the dash-board or frame of the vehicle, and is characterised by substantial construction.

THE Great Western Railway Company have inaugurated new arrangements in connection with the Holt and Farndon motor-'bus service. The fares have been reduced, and there is a late trip arranged for Saturdays.

The 24-h.p. Leon Bollee-Car built for the Hon. Arthur Stanley, M.P., a Vice-Chairman of the Automobile Club.

THE Invicta Motor Accessories Company has been registered with a capital of £1,000, to acquire the business of electrical engineers and motor ignition manufacturers carried on by Mr. L. Brandes, at St. John-street, Coventry, as Brandes and Co.

THE Sirdar Rubber Company, Limited, are now supplying their registered grooved Royal Sirdar Buffer tyres. This tyre, although a single tyre, acts as a twin tyre, and is claimed to prevent side-slip and can be fitted to any existing Royal Sirdar Buffer rims, or, in fact, to any motor-car wheels.



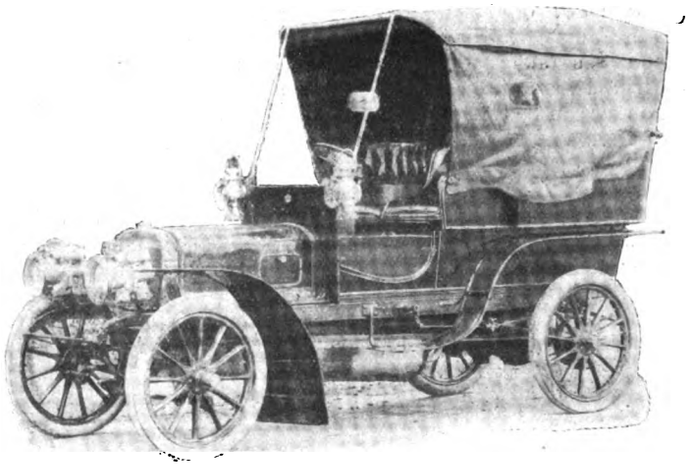
LONDON is about to witness a steady increase in the number of motor-omnibuses in use in its thoroughfares. The Milnes-Daimler double-deck 'bus which has been in use for some time by Messrs. Thomas Tilling, Limited, has evidently proved satisfactory, as we learn that orders for a further thirteen vehicles have been placed by the company.

THE Birmingham and Midland Motor Omnibus Company has been registered, with a capital of £60,000 in £1 shares, to adopt an agreement between the Birmingham Motor Express Company of the one part and this company of the other part, and to carry on the business of motor-car, omnibus, van, and cab proprietors.

A LIST of notable performances with the "Castle" accumulators has been prepared by the United Motor Industries, Limited, and which will be sent by them to motorists interested in such matters. Their new list also includes reference to the "Castle" rubber buffers for strapping or fastening to the springs of cars to deaden violent shocks. The Universal set of box spanners for cars is another speciality of the firm.

A CIRCULAR relating to their specialities has just been received from the Lacre Motor Car Company, Limited.

THE illustration herewith depicts a new 15-h.p. four-cylinder Darracq car with side entrance, canopy glass front, and curtains,



recently supplied by Mr. A. F. Garnham, of Ipswich, to one of the local magistrates. The vehicle is one of the smartest cars in the district.

PERMISSION has been given by the King to a number of motorists to go through certain roads in Windsor Great Park, provided they travel at a reasonable pace.

MESSRS. R. AND J. PULLMAN, LIMITED, of Westbrook, Surrey, are arranging for the repair and housing of motor-cars. They have now in operation a series of notice-boards acquainting motorists of the nearest telegraph office, etc., should breakdowns occur.

ONE of the most popular resorts in Surrey is "The Hut," at Wisley, and another is "The Lion," at Ockley. These two houses belong to the Surrey Public House Trust, of which Earl Grey was the founder. The Trust has now purchased the equally well-known Burford Bridge Hotel, at Box Hill, which, with its beautiful grounds, wild fowl, etc., must surely be known to most of our southern readers.

WE illustrate herewith the 20-h.p. Thornycroft petrol car which has just been dispatched to India to take part in the Delhi-Bombay race for the Gaikwar of Baroda's Cup. The car, which is one of the Thornycroft Company's standard type, has

been sent out for Mr. A. J. Dent, of the firm of Gladstone, Wyllie and Co., of Calcutta, who is entering it, and will drive it in the trial. His previous car, which he took out to India with him some time ago, was a 10-h.p. Thornycroft, which he found eminently satisfactory.

THE principal floor at the Collier Tyre Company's new premises, 127 to 130, Long Acre, W.C., measures 130 ft. by 65 ft.

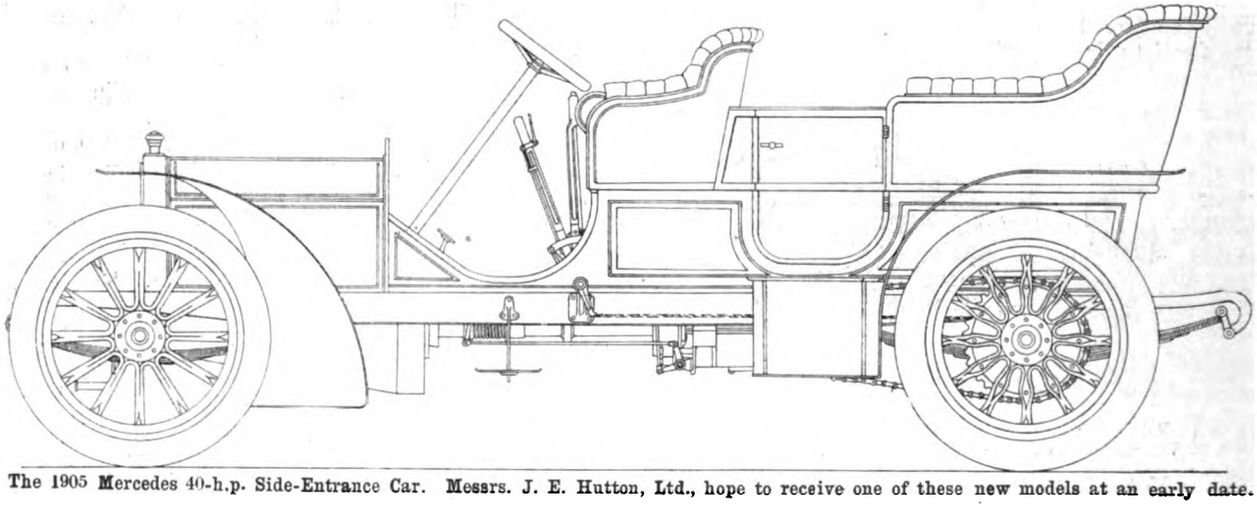
THE three Fiat racers which will compete for Italy in next year's Gordon Bennett cup race will, it is stated, be of 100-h.p.

IT is reported that the Hotchkiss Company are building a six-cylinder racer for the eliminating contest for the French team for the 1905 Gordon Bennett race.

FOR taking down a signpost erected by the Bedford County Council at Eaton Socon under the Motor Car Act the owner of the property adjoining the road on which it was put up has been fined 5s. and costs at the Bedford Petty Sessions.

TO the Home Workers' Series, published by Messrs. Dawbarn and Ward, Limited, Mr. R. H. S. Williams has contributed a small book entitled "How to Build a Bicycle," in which are included some hints with regard to the construction of motor-cycles.

THE Mercedes Motor Works, Limited, has been registered with a capital of £2,000 to acquire a licence from the Mercedes Company, Limited, for the manufacture in Great Britain of Mercedes engines for motor-cars, motor-boats, and other purposes.



THE proposed motor service between Dartford and Swanley Junction is being seriously encouraged, and the local committee is in negotiation with the Farningham Motor Company regarding the terms of a daily service. The route will probably be through Wilmington and Hextable.

MR. H. GUTTERIDGE, who was for many years with the motor department of Messrs. Gamage, has opened premises at Cambridge Circus, Shaftesbury Avenue, W., for the sale of motor accessories and clothing of all kinds as well as for automobiles. The style of the new firm is H. Gutteridge, Limited.

MESSRS. BARKER AND COMPANY, the well-known coach-builders of Bedford Street, London, W.C., after building carriages for over 200 years, have now established a thoroughly up-to-date motor body department, from which they are turning out light, but well-made highly-finished motor bodies.

FROM Messrs. Straus and Company, Limited, comes a little handbook which, in addition to forming an illustrated catalogue of the various types of Fafnir petrol motors for which they are the sole agents in this country, contains some useful matter of interest to motorists relating to petrol densities at different temperatures, metrical weights and measures, and horse-power. Copies of the booklet can be obtained from Messrs. Straus, 211, Upper Thames Street, London, E.C.

A NOVEL method of illuminating the rear number of motor-cars is being introduced by Mr. J. B. Beal, of Pocklington. The rear number is illuminated from the front lamp by means of a burnished tube extending to the rear of the car. On the end of the tube is fitted a box in which the numbers are cut out, so that it is impossible for the numbers not to be illuminated without the driver's knowledge, as the light is taken from the front lamp, in which are fitted two burners and reflectors.

The 1905 Mercedes 40-h.p. Side-Entrance Car. Messrs. J. E. Hutton, Ltd., hope to receive one of these new models at an early date.

MR. E. C. WILLS, the eldest son of Sir E. P. Wills, Bart., K.C.B., is an ardent motorist, and is shown in the photograph on page 837 on his latest acquisition, supplied by the Bristol Motor Company, Limited, of Bristol. At the time our photograph was taken Mr. Wills was on his way from Bristol to Barnstaple, and the roads were in a slimy and dangerous condition, as can be imagined from the state of the mudguards.

ANTI-FREEZING mixtures occupied the attention of the members of the Milwaukee Automobile Club at the first of its series of winter meetings. Dr. Louis Fuldner read a paper discussing various solutions, and a general expression of opinion followed. The proper solution of calcium chloride, according to the experience of those who advocated its use, is four pounds to a gallon of water. This solution will not freeze above a temperature of thirty degrees, and does not injure the tubing. A twenty per cent. solution of pure glycerine stood next in favour.

MR. ROBERT PRATT, of South Bridge, Cupar, N.B., has sent us a sample of a new liquid anti-rust preparation known as "Spirit-Otium" he has lately introduced. It is intended to take the place of vaseline in protecting the bright parts of motor-cars and cycles from the effects of wet and rust; it is applied by means of a small brush, and not only acts as a protective coating, but on being cleaned off leaves the parts as bright as when new. Although "Spirit-Otium" has only been on the market a short time, it has, we understand, already been extensively adopted in Scotland

THE Parsons Motor Company, Limited, has been registered with a capital of £5,000, to carry on the business of manufacturers of and dealers in motors, motor-cars and vans, etc., and to adopt various agreements. The first directors (to number not less than two nor more than five) are Messrs. W. H. Parsons, J.P., H. Parsons, W. White, and G. S. Pettigrew, and the registered office is at Town Quay, Southampton.

MR. W. A. SALE, of Luton, gives a remarkable instance of the steadiness of running of the motor-car, an instance which should do much to reassure those who are of opinion that vibration is a serious obstacle in the modern automobile. Mr. Sale recently had occasion to fill up his acetylene lamp with water at Hockliffe, and unwittingly left the jug from which the water had been poured standing on the step of his Humber car. On arrival at Luton, nine miles distant, Mr. Sale found the jug still on the step.

SOME time ago Messrs. Matthew Wells and Company, of Manchester, sent us a sample tin of their "Wellsaline" lubricating oil for air-cooled engine. The oil is quite free from acids or impurities. We have given the sample a practical trial, and find that it fulfils all the claims made for it, no lubrication troubles whatever having been experienced. Messrs. Wells also supply lubricating oil for water-cooled motors and for steam engines, and in view of their great experience in this branch we do not that these are equally efficient as we have found that for air-cooled motors.

CONTINENTAL NOTES.

An Austrian Military Motor-car.

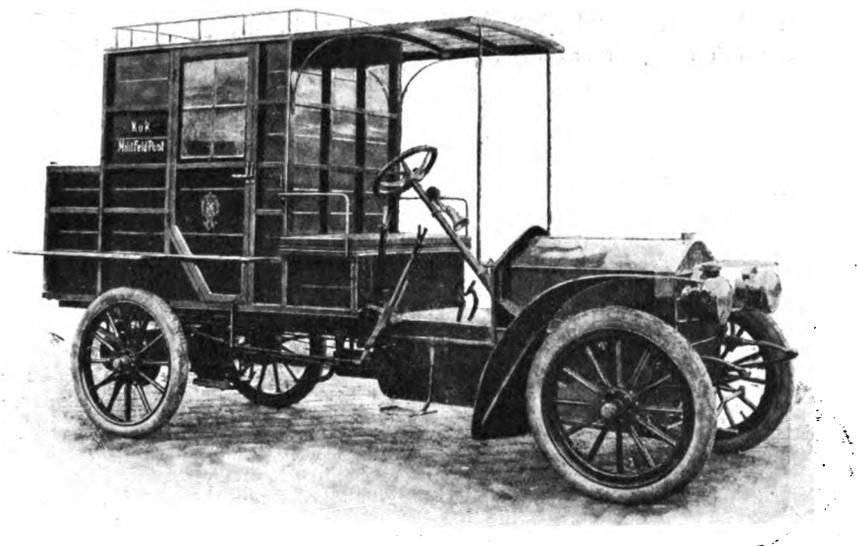
The Austrian Daimler Motor Company, of Neustadt, Vienna, are at present engaged on the construction of a new military motor-car, which is to be fitted with a quick-firing gun. The latter will be so arranged that it can be raised or lowered at will and also that it can be set at any angle on the car.

◆ ◆ ◆

German Cars for England.

A report is current to the effect that the Scheibler Automobil Gesellschaft, of Aix-la-Chapelle, has secured a contract from an English syndicate for no less than 150 motor-wagons and omnibuses.

◆ ◆ ◆



Public Services in France.

Arrangements are in hand for the establishment of a public motor-car service between Enghien, St. Gratien and Montmorency. The vehicles to be used will be De Dions, with 22-h.p. four-cylinder motors, and have accommodation for twenty passengers.

◆ ◆ ◆

French Trials of Electric Vehicles.

The trials of electrical vehicles proposed by the "Auto" have already been alluded to in the *Journal*. It has now been decided to hold the trials in May next. The competition will be directed to deciding the merits of the vehicles for town and suburban service, and will take into consideration the cost of up-keep per day for the distance run, the relative comfort, ease of control, and silence of the vehicles, and the price. There will be three categories, or classes, as follows:—Class 1.—2-seated vehicles, of a maximum weight of 1,300 kilogs. Class 2.—4-seated vehicles, maximum weight 1,500 kilogs. Class 3.—6-seated vehicles with luggage carrier to take 30 kilogs. per passenger, maximum weight 1,800 kilogs. All classes may have either open or closed bodies, or bodies which may be opened or closed at will, but they must all be completely upholstered. The vehicles must have at least one double-acting brake, and also a sprag. The number of entries is not limited, but no manufacturer may enter two vehicles of similar type and dimensions. For each car entered before the 15th March a fee of 20 francs must be paid, the entry fee being doubled after that date. Entries close on the 1st May, 1905. The trials will consist of eight daily runs of about 100 kiloms. in Paris and suburbs, returning each evening to the charging station.

The above Illustration depicts the Military Field Mail Delivery Van furnished by Messrs. M. A. Wyner for use in the recent Austrian Manœuvres.

◆ ◆ ◆

A Public Service in Sweden.

The Jungner Accumulator Company has recently started a public service of electrical motor-omnibuses in the town of Norrköping. Three vehicles are in use, having accommodation for ten passengers and the driver. They are provided with a battery of Jungner accumulators, and are designed for a speed of twelve miles per hour.

◆ ◆ ◆

A German Motor Volunteer Corps.

The Geman Automobile Club is taking steps to organise a Motor Volunteer Corps on the lines of that in Great Britain.

Public Services in Germany.

A company has just been formed at Emmerich with the title Die Automobilfahrt Emmerich-Cleve to run a public service of motor-cars between the two places named. In Breslau, too, the Automobilverkehrs Gesellschaft has been organised to establish a public service between Breslau and Klarenkranst, twelve miles away, and for the transport of the mails between the two places.

◆ ◆ ◆

The British International Cup for Motor-Boats.

At the International Motor-boat Conference held in Paris a few days ago it was decided to hold the race for the British International Cup for motor-boats on September 11th, 1905, in the Gulf of Arcachon. This is a fine piece of inland water on the west coast of France, about thirty-five miles south-west of Bordeaux. It was also resolved that in the case of motors driven by paraffin it shall not be permissible to carry petrol on board for the purpose of starting the engine.

◆ ◆ ◆

The Crawhez Cup.

It is announced that the Baron Pierre de Crawhez, the well-known Belgian *chauffeur*, is presenting an international cup to be competed for by motor-car builders. The contest will be over a distance of 500 kilometres, and will be one of both speed and reliability. Each firm competing will have to enter a team of three cars, and marks will be allotted in accordance with the order of arrival at the finishing point, the firm securing the least number of points holding the cup for a year. The cars not completing the whole distance will be credited with as many marks as competitors, plus one.

◆ ◆ ◆

The Burton Motor-Boat Challenge Cup.

The cup presented by Mr. A. Burton to the Automobile Club of Cannes is to be competed for annually at Cannes five days at the most after the last race at Monaco. It will be an International event, open for motor-boats not exceeding sixty feet in length, the distance being 100 kilometres. To secure the cup outright it must be won three years in succession.

◆ ◆ ◆

Gordon Bennett Race.

New courses for next year's Gordon Bennett race are being suggested almost daily. The authorities of the Department of Eure-et-Loir have proposed a circuit in the Beauce and Perche districts. It embraces a run from Chartres to Nogent-le-Rotrou, 56 kilometres, to Chauteaudun 62½ kilometres, and from Chateaudun to Chartres 44 kilometres. There are three level crossings, and at least three neutralisations on the course. The International Commission of the race is to meet at Paris on the 12th inst., to decide on the regulations for next year's contest.

◆ ◆ ◆

Motor-Cars in the Russian Postal Service.

The Union Motorfahrzeugfabrik Gesellschaft, of Nuremburg, Germany, has lately supplied a number of petrol motor-vans to the Russian postal authorities. The vehicles are of two sizes, both having the Union Co.'s system of friction drive; the smaller vans are of 6-h.p., and are designed to carry mails up to a load of 10 to 12 cwt. at speeds up to twenty miles per hour. The larger vans are being used in the parcels post service; they are of 8-h.p.

CORRESPONDENCE.

THE SLUMP IN THE VALUE OF AUTOMOBILE CLUB PATRONAGE.

The following letters have been addressed to the Secretary, A.C.G.B.I. :—

November 29th, 1904.

The Secretary.
Automobile Club, 119, Piccadilly, W.

DEAR SIR,—I have been informed that the Automobile Club of Great Britain and Ireland purpose giving their patronage to the exhibition held at Olympia by the Society of Motor Manufacturers. I would remind you that upon more than one occasion the exhibition held under the auspices of the Automobile Mutual Protection Association, and controlled by myself, has received the patronage of the Automobile Club, and this patronage I have found most useful and as such have paid for. I understand the question of payment is distasteful and objectionable to your committee, and would therefore ask your committee to extend to the Agricultural Hall Show the same consideration which they have to the Olympia Show, and grant to that exhibition the patronage of the Club. Trusting you will bring the matter before your committee.—I remain, yours truly,

(Signed) C. CORDINGLEY.

December 3rd, 1904.

DEAR SIR,—Regarding my communication of November 29th, and your reply thereto of the same date, upon further reflection I have decided to withdraw my application. My reasons for doing this are, that I should not care to bind myself to support what may be in the view of myself and my friends something which may not be advantageous to the industry. Freedom of action and thought are to me far better than the doubtful privilége of the support of an organisation which last year assessed its value at £500, but which this year has apparently depreciated to nil.

Regarding the club's patronage, which was for the third time accorded (and paid for) my exhibition last year, I distinctly stated to club officials that it was not worth having; I did not want it; and only upon entreaty did I accept it. Kindly therefore, take this communication as a definite withdrawal of my application of November 29th, and in the meantime, I beg to remain.—Yours truly,

(Signed) C. CORDINGLEY.

THE LANCHESTER CAR.

TO THE EDITOR OF *The Motor-Car Journal*.

SIR,—I have much pleasure in answering "Enquirer" as to the Lanchester car, being a *bona fide* enthusiast and having no interest whatsoever in the firm. I have driven Lanchesters for the last two years, an air-cooled car for nine months and then their new water-cooled 12-h.p., and would not exchange my car for any on the road. I have not had a very large experience of other cars, but have handled a 20-h.p. French car of well-known make, and am able to draw a comparison between the different types.

Firstly, up to forty miles per hour (as far as my experience goes) I think the tiller steering ideal. As placed on the Lanchester, it lies in a most happy and comfortable position for the natural repose of the arm. Contrary to general opinion, there is no inconvenience owing to "backlash," the "feel" being so delicate it is particularly handy on greasy roads and in traffic.

(2.) Air cooling was successful, but the 12-h.p. water-cooled now turned out is an immense improvement in every way. (3.) Range of speed on any one gear is quite sufficient, I can get as low as six to eight miles per hour on the top speed, and can pick up on the top speed at even lower owing to the admirable clutch. (4.) The governor levers give perfect control, and have this advantage over the throttle, that when running slow the petrol charge is entirely cut off in proportion to the speed, and thereby economises fuel and keeps the engine cool. Either cylinder can be cut out at will, and if one is set to cut out oftener than the other, the only result is a little more work on one cylinder than on the other and a loss of speed. (5.) As the right hand naturally rests on the steering arm, so the left hand naturally drops to the speed levers, and should you not be familiar enough to find, with certainty, the levers in the dark, it is perfectly natural and reposeful to let the left hand rest on the speed lever. (6.) I can say in answer to this query, that I have no trouble, and the car is running as well as ever after 8,500 miles. I may add that all parts liable to wear are easily got at and simple to "fake up." (7.) Nothing can possibly be safer or quicker in an emergency than the Lanchester system of speed levers and brakes, one movement of pulling back the lever frees the engine and applies the brake. A Lanchester can be jumped back and forth (from forward speed to reverse) as no other car can. (8.) As regards hill-climbing, the Lanchester for its *listed* h.p. is unsurpassed, and in a give-and-take run can hold its own with much higher powered cars, owing to the way it can climb on its top speed after other cars have long since changed down. The peculiar springing gives the car a delightfully easy motion, and the ample accommodation for luggage is invaluable on tour.

I would like to draw attention to a point often overlooked, viz., the wire wheels. I do not think a single case has been recorded of the collapse (except, of course, a regular smash) of the Lanchester wheel; it is a scientifically built wheel, no stretching in damp weather, or contraction in dry, no wearing loose; they last for ever, will run with half the spokes knocked out, and can be repaired at home. The Lanchester is the only genuine British car (as far as design goes); it is a good car, and deserves success.—Yours truly,

ARTHUR A. PAZOLT.

TO THE EDITOR OF *The Motor-Car Journal*.

SIR,—I have a Lanchester car and herewith give my experience of the machine. The questions are answered as numbered by your correspondent. 1. Tiller steering is preferable to wheel for locomotion in traffic but not for speed. 2. I do not consider air cooling a success. 3. Speed variations very satisfactory and comfortable, but great care required in adjusting same; range of speed variation quite equal to any other car. 4. Governor levers do not give as great control as throttle levers; one or both cylinders can be cut out; machine gets hot, loses power and speed if one lever is set to cut out the governors oftener than the other. 5. Control and speed levers as placed in Lanchester equally good as those placed on the off side of other cars. 6. The car is decidedly trouble-some to keep in order. If you go into a strange garage as I did when touring, there will not be a man in the place to adjust a screw, owing to the peculiar construction of the car. My bill for repairs in six months is £70, besides three new tyres and £10 for repairing tyres; distance traversed 7,000 to 8,000 miles. 7. Control and brake first-class. 8. Hill-climbing speed and comfort very good. In conclusion in my opinion this make of car is not adapted for long distances, averages of 500 miles per week, "real touring." The delicacy and intricacy of the machinery renders the machine too liable to get out of order.—Yours truly,

X.

TO THE EDITOR OF *The Motor-Car Journal*.

SIR,—In reply to a letter which appeared in the *Journal* of the 26th ult., I give the following information as a disinterested owner and from my own practical experience.

The tiller steering is far more comfortable than the wheel, being natural position of the arm when resting. It is possible at an instant's notice to practically turn the car at right angles without any danger of upsetting the vehicle, owing to the wonderful way in which the car is sprung. In the wet weather you have a greater control over the car, being able to bring it into track again the moment it begins to skid, and owing to the length of the car it gives you more time to act and correct it. I might mention that it is possible to do anything with the car in the grease by one who has good judgment and nerve. The only disadvantage is that it is impossible to turn round in an average-sized road without reversing and going forward again, owing to there being insufficient range of lock.

The air cooling is perfectly satisfactory, provided you keep the fans clean after each run (which is not much trouble) keep them properly lubricated, and if the car is driven properly.

It is impossible to control the speed by means of the ignition.

The governor levers are quite as efficient as a throttle lever as far as control is concerned, but if it is desired to drive at, say, eighteen miles an hour without declutching, as the governor blades cut in and the explosions take place, the car seems to run in jumps and starts; if, however, the levers are raised altogether the running is all that could be desired. One or both cylinders can be cut out at will. If you raise one governor lever without the other, one cylinder does all the work.

The levers between the seats are most convenient, being well within reach at a moment's notice.

I think the Lanchester will compare with most cars of its own weight and horse-power for speed. It will climb practically any hill on lowest speed.—Yours truly,

M. L. RENDRAG.

MAGNETO IGNITION.

TO THE EDITOR OF *The Motor-Car Journal*.

SIR,—The question of magneto ignition has taken a firm hold on the public, and it seems to me that the ordinary high tension will soon die out. Try a car fitted with both ignitions, i.e., high tension magneto and ordinary high tension. It will go certainly 10 % better on the magneto, the increased speed being doubtless due to the richer spark. People say, "Keep the ordinary high tension as a reserve." Well, the chances are that in the remote (as magnetos give practically no trouble) occasion when recourse is had to the ordinary ignition, the cells will be down through having been out of use for so long.—Yours truly,

MAGNETO.

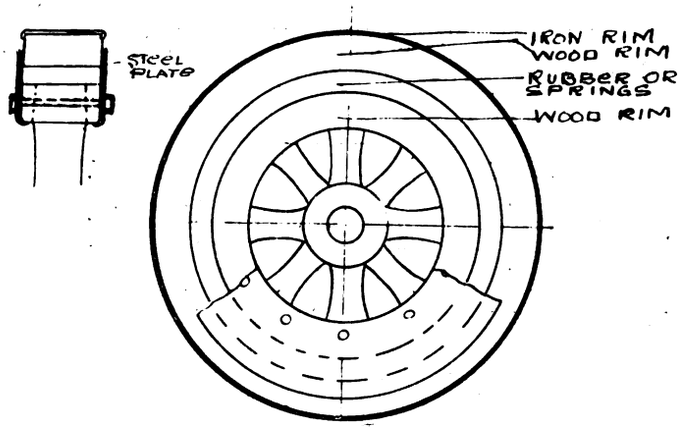
COST OF RUNNING.

TO THE EDITOR OF *The Motor-Car Journal*.

SIR,—I should like to express my thanks to "S. C. G." for providing your readers with the interesting particulars given in his letter. This is the sort of information which is required by prospective motor-car purchasers, and if any of your readers can give further particulars

Digitized by Google

as to the cost of running cars per year, I am sure there are many of us who would be extremely thankful.



Personally I should be glad to hear from anyone regarding the upkeep of a motor-van with solid tyres, or at least solid tyres on the driving wheels.—Yours truly,

J. G. R

WHEELS FOR MOTOR-WAGONS.

To the Editor of *The Motor-Car Journal*.

Sir,—I am enclosing you a rough drawing of a new wheel for steam wagons and other heavy vehicles which I am putting on the market.

As you can see by the sketch, there is a double rim—an ordinary outer rim to which the iron tyre is shrunk, and an inner rim to which the spokes are attached in the ordinary manner—between which the two rubber or steel springs are inserted. Where springs are fitted, the space between the two rims is greater than when rubber is used. The outer rim is kept in position by a steel plate as shown.

There is a great need for a wheel of this sort, especially where steam wagons are used by city corporations for night work, etc. Many have, and are still endeavouring to, overcome the trouble of vibration over sets, and the noise, by trying an altogether spring wheel, and in some cases "wood to the road" wheel. But, after many weeks' practice and experiments with the Thornycroft steam wagons, I am convinced that the only and proper mode of attaching springs to the wheel itself is in the manner illustrated. The device will not alter the general appearance of the wheel very much. I should like some faults to be found by some of your readers interested in this question.—Yours truly,

C. De Rouet.

SIX VOLTS FOR IGNITION.

To the Editor of *The Motor-Car Journal*.

Sir,—With regard to Mr. W. F. Rhodes' enquiry in the last issue of the *Journal*, there are many motorists who recommend running on six or eight volts instead of the usual four volts. Nevertheless, before he makes the change, Mr. Rhodes should find out from the manufacturer of the coil fitted to his car what it is capable of standing, as there are undoubtedly many coils not capable of standing much more than four volts.—Yours truly,

Regina.

To the Editor of *The Motor-Car Journal*.

Sir,—I have used 8 volts on a 1902 type Oldsmobile for two years. The coil was supplied with the car, but gave trouble with the dry cells supposed to work it.

It would be best to ask the makers of a coil whether it would bear a higher voltage, as there may be danger of breaking down the insulation on a short circuit through heating. I risked it.—Yours truly,

Belfast. J. Brown.

THE CLYDE CAR IN THE HEREFORD TRIALS.

To the Editor of *The Motor-Car Journal*.

Sir,—In Mr. Worby Beaumont's highly interesting and instructive paper on the "Development of the Light Car" he refers to the comparatively low petrol consumption of the Clyde car, as though an error had been made in the quantity registered. The above trial did not show up the true capabilities of the car, for the following reasons.

On the first run up Frome's Hill a large non-competing car ran into the Clyde car (as reported in the press at the time), and bent one of the front wheel axles badly, also the steering gear. In spite of this the driver continued his journey with the front wheels running inwards, and the car always tending to steer to one side of the road. A protest was lodged, and the judges next day gave permission to repair the damaged parts. Owing to the impossibility of effecting the necessary repairs in time to start with the next run, it was decided to drive the car in its crippled condition to the end of the trials.

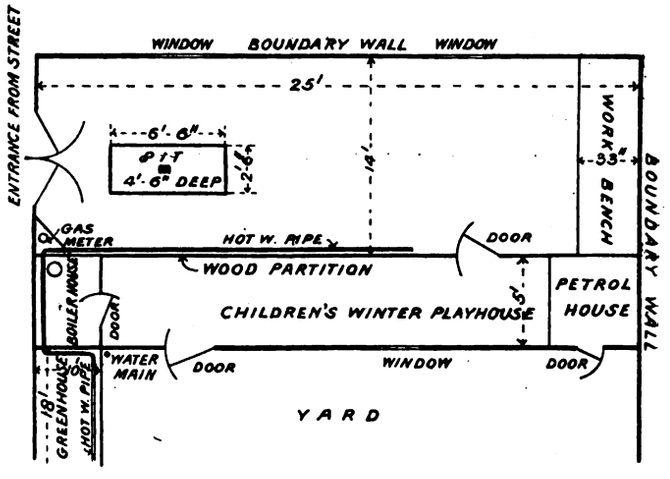
The effect of the front wheels running inwards was to act as a brake, so much that at the finish the treads of the tyres were ground nearly through to the canvas. In addition to this, the bent axle caused the cone of the ball bearing to bend on the cup so hard that it was afterwards found that the cone had turned blue owing to the friction. This car before and since the trials has run regularly over ordinary roads on a consumption of one gallon to every fifty to fifty-five miles, with a full load, and this is not unusual, as other Clyde cars of its type will give the same result.

As showing the extra work the engine had been doing owing to the accident, the car, on its return from the trials, and before being repaired, was driven up a hill with a gradient of one in seven. It only got up the hill with difficulty, with the driver in alone, whereas before the trials it took the hill with driver and passengers at 8½ miles an hour. Still, in these trials there is a great element of luck, and it is now a matter of waiting till the next trials, so as to give the Clyde another opportunity to show its real capabilities.—Yours truly,

C. H. Wait.

TILLER STEERING.

To the Editor of *The Motor-Car Journal*.



Sir,—In the *Journal* of December 3rd there are three letters in reply to query re Lanchester car. Each writer distinctly gives his opinion that the tiller is preferable to wheel steering. May we assume that all other drivers of the Lanchester are of the same opinion? Also, do not those who have tried *any other* form of tiller consider it more handy in every way than the wheel? If this is so, why do not makers think about it, and offer us the best, simplest, and cheapest form of steering, instead of the more expensive and inconvenient wheel?—Yours truly,

A.B. 50.

MOTOR-CAR HOUSE.

To the Editor of *The Motor-Car Journal*.

Sir,—Having read your note respecting motor-car houses in the *Journal* of the 12th ult., I beg to state that I am not used to drawing to scale, but have enclosed you a ground plan of the motor-house I had built about two and a half years since. I find it most satisfactory, and think other motorists would find one built on similar lines advantageous. I will therefore endeavour to explain the sketch. In the first place the house is 12 feet high, with tile roof and a boarded floor, so as to keep all damp from dripping on the car, with a manhole in so as to allow a place for lumber. The house has 9 in. walls all round. The entrance from the street to boundary or end of working bench is 25 ft., the width is 14 ft., with a lean-to greenhouse, 18 ft. long by 10 ft. wide, and same height as the motor-house. The entrance has two doors opening inwards, with two glass panels in each. The pit is 6 ft. 6 in. long, 2 ft. 6 in. wide, and 4 ft. 6 in. deep, with 9 in. brick wall, 8 in. concrete bottom; also a drain to carry water away when washing the car down. The floor is 8 in. concrete. Two windows

to give light are provided; also a bench to do minor work. The house is heated with hot water pipes, as you will see; the pipes run out of the greenhouse through the boiler-house into the motor-house. Both places can be heated at one time or separately, by simply turning one or other of the cocks. The boiler is heated by gas, and has a 3 in. pipe to take the fumes of the burnt gas away. Divided off by a partition is a small play-house for my children in wet weather. The petrol store has 9 in. walls, bricks laid in cement; 9 in. concrete roof. 8 in. concrete floor, with fireproof door facing the yard. The door has about forty ¾ in. holes near the top, so as to allow any gas escaping from cans to get away.—Yours truly

F. W. Allbones.

Digitized by Google

STEAM CARS.

To the Editor of *The Motor-Car Journal.*

Sir,—Mr. T. E. Henderson states that the steam car has all its energy stored ready for a short run or climb, and can do it well, but afterwards it is not always ready to continue its performance. The idea that steam cars accumulate a great pressure beforehand is, I think, now quite exploded, and I may say that standing still waiting for the signal to start on a short run or climb is the worst start it is possible for a steam car to have.

On the other hand, it is well known to those who have had to do with steam car racing, that if a good timing is to be made the steam pressure must be kept down 25 per cent. below working pressure before the start, in order that the fire may come on full immediately the car is started, the boiler making steam up to full working pressure whilst racing. I should like to point out that on the Mount Washington hill climb, a little 8-h.p. Stanley steam car came off better than a 40-h.p. petrol car, and not on a short climb. Also, I do not think Mr. Henderson has handled a modern steam car, and I shall be pleased to demonstrate that 30 miles per hour can easily be maintained up hill and down.—Yours truly,

B. 126.

AN INTERESTING MOTOR QUERY.

To the Editor of *The Motor-Car Journal.*

Sir,—Although warm air is considered to furnish the best mixture for a petrol engine, it is the experience of practically every motorist that in the cool of the evening, after sunset, the power of his engine is immensely increased. Although it may have lagged during the warm, bright hours of sunshine, the fall of night brings with it an acceleration of pace that is undoubted. There are evenings when the motor seems fairly to "take the bit in its teeth," so to speak, causing the car to simply romp home. Good as it may have run during the day, it then runs better, no matter how the ignition or throttle levers may be regulated. Despite the fact that it is at variance with accepted beliefs, the phenomena or contradiction has never been satisfactorily explained; indeed, small attention appears to have been paid to it, although it would seem to offer a field of possible discoveries of value. Various reasons have been advanced as to the cause of this change in the behaviour of a motor, there being many who consider that it is not due so much to change of temperature as to atmospheric conditions. It would therefore be interesting if some expert motorist could define exactly what takes place, as then an attempt might be made to supply the same conditions artificially during the day, thereby getting so much more power out of the same quantity of fuel.—Yours truly,

Inquisitive One.

STARTING TROUBLE.

To the Editor of *The Motor-Car Journal.*

Sir,—Will any of your readers kindly tell me how to overcome the following difficulty? I have an 8-h.p. car, single cylinder Simms' engine, magneto ignition, which I can always start at the second turn of the handle when commencing a journey or when the engine is cold, but after running some miles and stopping, I have to turn sometimes a dozen or more times to start the engine. Why should it be more difficult to start when the engine is warm; would the auxiliary accumulator set for low tension magnetos remove the difficulty? How are they used? I should be glad of the experience of any of your readers who have used same.—Yours truly,

Fired Out.

[We are inclined to think that "Fired Out's" trouble is not at all to do with the ignition, as if this were the case he would have the same difficulty when starting cold. The trouble is generally reversed, trouble in starting cold and not when hot. We should be rather in favour of trying the compression, and if found to be weak when hot, use a somewhat thicker lubricating oil. This appears to be the only possible trouble, as the engine will readily start when the lubricating oil is cold and will cause a good compression, but invariably does so when it is warm and likely to let the compression pass the piston.]

WINTER PRECAUTIONS.

To the Editor of *The Motor-Car Journal.*

Sir,—Now that the winter is coming on, I should be glad to know what means I may safely employ to heat my motor stable. The shed is with wood roof and tile floor, and as it is only temporary, I do not wish to put in a hot water installation. Would it be permissible to use a coke stove of the "Tortoise" type in a corner of the shed, or would the stove have to be outside, and the flue simply carried through? Petrol is stored outside, only the small supply in the tank and carburettor on the car being in the shed.—Yours truly,

W. J. L.

[It would be an unwise risk to have anything of the nature of an open fire, even that of a "Tortoise" stove, in the motor house, as one never knows when a car may return from a run with a leaky petrol tank or pipe. The stove should be outside, with flue through the stable, though it is would be rather uneconomical in fuel with an iron stove unless it could be arranged to warm an adjoining room. If the stove is entirely outside, one of those with tile bodies would seem preferable. We have known of an inexpensive hot-water apparatus being used thus rigged up with a couple of discarded car radiators and a coil of copper pipe over a paraffin heater as boiler, the radiators being coupled in parallel, to get easy circulation.]

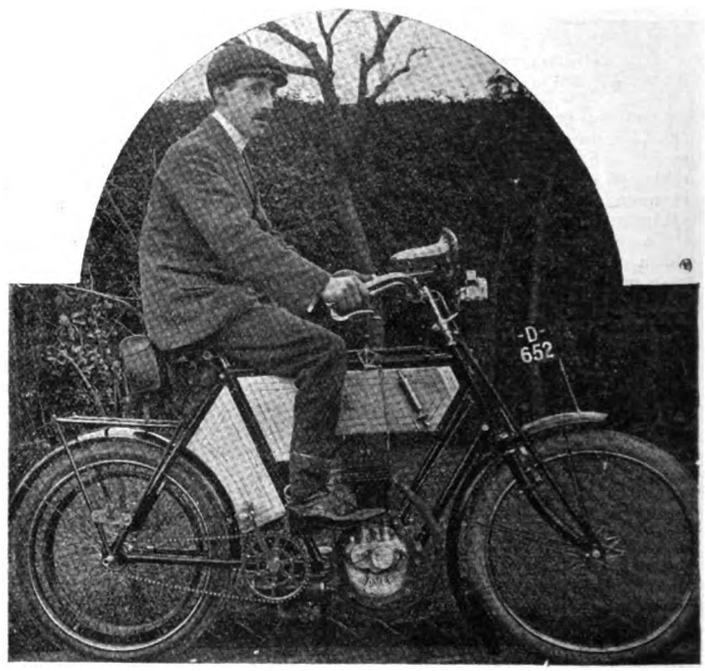
NON-SLIPPING TREADS.

To the Editor of *The Motor-Car Journal.*

Sir,—My car is put by for the winter. What is the best course to preserve the tyres? Non-skids are constantly referred to, but I notice no reference to "Lemperurs." My experience is that one alone seems to afford complete protection; two not being tried, as one sufficed.

On first using this device two covers were in quick succession burst. The tyres were Dunlops, and had travelled about 2,000 miles. Is this the fault of the tyre, the non-skid, or otherwise? R placing with new covers, the result has been very satisfactory.—Yours truly,

George Drinkwater.



Isle of Man.

[We shall be pleased to have the experience of other users with regard to non-skidding devices.]

FOOT RESTS FOR MOTOR-BICYCLES.

To the Editor of *The Motor-Car Journal.*

Sir,—I thought perhaps some of the readers of the *Journal* would like to hear of a foot rest I have made and put on my motor-bicycle. It will be seen from the photograph how much more comfortable it is to have one's feet on the rest than it is on the pedals. I have found it of great advantage. After one has ridden 40 miles without a stop, one gets

quite stiff, with the feet always on the pedals; but now, with my feet on the rests, I can ride 40 or 50 miles without getting off, and feel just the same as when I started. With the rest fitted in front of the pedals, one sits right on the springs of the saddle and does not get the shaking caused by the holes in the road. The rests do not, of course, interfere with the pedals.—Yours truly,

A. C. Beech.

Motor-Cabs.—In reply to the inquiry *re* motor-cabs by a hotel proprietor in our last issue, the Dixi Motor, Limited, 20-22, Brompton Road, S.W., and Messrs. Delamotte and Foster, 422, Birkbeck Bank Chambers, E.C., are able to supply motor-cabs for hotel and station work.

Invicta Accumulators.—A Belfast reader of the *Journal* asks for the name and address of the firm who manufacture the Invicta accumulator for motor-cars.

Primary Cells for Charging Accumulators.—Several correspondents have written in reply to Mr. C. Crompton's letter of last week to the effect that the cells he describes are those of the Boron Battery Company, of Liverpool.

Induction Coils.—Replying to Mr. F. J. Gregg, the Guenet induction coils are made by M. J. Guenet, 5, Rue Montmorency, Paris.

A Satisfactory Hotel.—A London motorist writes enlogistically of the treatment he has received at the White Lion Hotel, Devizes, and also of the reasonable charges at the hostelry, the proprietor of which is kindly disposed towards motorists.

Owners for Tyres Wanted.—The police authorities at Chippenham, Wilts., have two motor-car tyres for which they are seeking the owners.

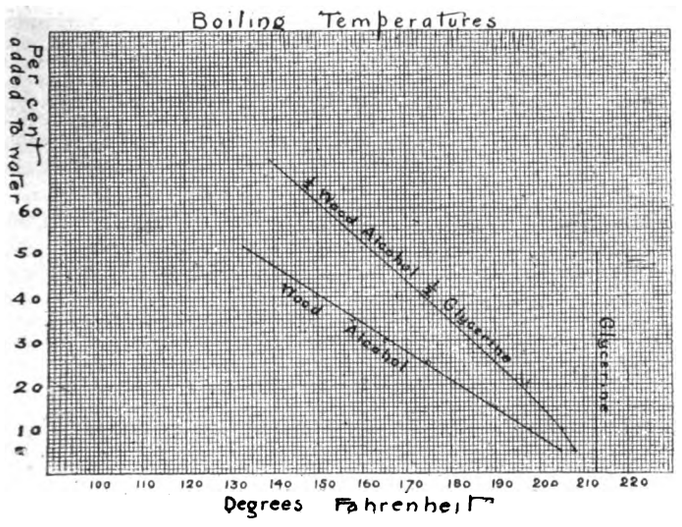
COLD WEATHER PRECAUTIONS.

ANTI-FREEZING EXPERIMENTS.



By HENRY SOUTHER.

SINCE my first article (see *Motor Car Journal*, November 12th, 1904, page 768), further investigation made to determine the relative good qualities of three anti-freezing mixtures has developed facts that place the water-cooled car beyond the point of risk or danger. It has been found that some machines containing a very small amount of cooling

liquid boil easily with alcohol on a mild day, but it must be stated, in connection with this, that the amount of alcohol used was greatly in excess of what is necessary for this season of the year. In my own case I added some 30 per cent. more than a month ago, and within a few days found that I still had 20 per cent. left, showing that the loss is not very bad from a financial standpoint with wood alcohol at 3s. per gallon.

The use of glycerine added to water is advocated by many and used successfully. It destroys any rubber tube connections slowly but surely that there may be in the circulating system, but that is not a serious matter. The percentage of glycerine required to meet a given temperature is very much larger than the percentage of alcohol required, and the cost is more than double It occurred to the writer that a mixture of alcohol and glycerine would, perhaps, after all, meet all objections best, and this has been tried. The accompanying diagrams show the curves for the freezing of various percentages of wood alcohol added to water, a

mixture of half alcohol and half glycerine added to water, and a mixture of pure glycerine added to water. One peculiarity in these curves will be noticed at once; that the wood alcohol curve is nearly a straight line; that the efficiency of the wood alcohol and glycerine mixture in meeting freezing temperatures increases very rapidly with an increase of percentage, and at about 30 per cent. is quite as efficient as the wood alcohol alone. This mixture is practically good for 10 degrees below zero. The glycerine curve is nearer a straight line, but its efficiency increased very rapidly after passing 30 per cent.; but it is seen that 30 per cent. glycerine will freeze at about 15 degrees F., and that to be safe for 10 degrees F., below zero, somewhere in the neighbourhood of 55 per cent. will be necessary.

The other diagram shows the boiling points of the three compounds. In boiling, a mixture of glycerine and water behaves very differently from the others—the glycerine raises the boiling point of water only about one degree, no matter what percentage may be added up to fifty per cent. Pure glycerine boils at about 330 degrees F., which point is so far from that of the boiling point of water that the glycerine behaves entirely independently, and the water boils, leaving the glycerine in a perfectly liquid state. The mixture of half wood alcohol and half glycerine is decidedly better so far as boiling is concerned than the pure alcohol mixture. From these results, it is seen that the half and half mixture with water is very good as far as freezing is concerned, and, also, fairly good as to boiling.

It, therefore, seems to me that if the half and half mixture is used motorists will get the best results, adding a small quantity of wood alcohol from time to time as the weather gets colder, to reduce the freezing temperature. The glycerine will stay there all the time as a constant without loss, and insure against any moderate freezing temperatures. If all glycerine is used, then a very large percentage is seen to be necessary. It is scarcely worth while to add less than 35 or 40 per cent., which will suffice for five degrees or ten degrees F. There is certainly no reason, with these data before one, why a water-cooled machine should not be run in any weather, and even left in a cold stable throughout the entire winter. It may fairly be said that the freezing problem is settled. —*The Motor World.*

CLUBS AND ASSOCIATIONS.

NOTTINGHAM.

THE fifth annual dinner of the Notts. Automobile Club was held at the Victoria Hotel, Nottingham, on Friday of last week, the company present including Colonel H. C. L. Holden (chairman of the A.C.G.B.I.), Messrs. Clay (Chief Constable of Nottingham), E. P. Hooley (surveyor of the Notts County Council), C. Hardy (president of the Notts Club), A. R. Atkey (hon. secretary), Dr. Herrick, Dr. Ashwell B. Granger, H. Belcher, Dr. Gass, J. C. Bennett, M. Ross-Browne, P. L. Jones, R. S. Clifford, W. M. Hutchinson. W. D. Foster, Dr. Palmer, G. H. Kirk, J. Anderson, Dr. Thomson, R. R. Latham, and the gentlemen whose names follow in the report. In the absence of Colonel Powell, Mr. Ross-Browne briefly proposed the parent body, coupling with it the names of Colonel Holden and Mr. Orde, who responded. Mr. Claude Johnson gave the "Notts. Automobile Club," and the secretary, Mr. A. R. Atkey. He paid a well-deserved tribute to the splendid services of Mr. Atkey. The last named gentleman, acknowledging the toast, said in all his duties he had invariably received splendid assistance from the gentlemen present, who always displayed a helpful spirit of enterprise and enthusiasm. The club had incidentally formed friendships and fostered a spirit of companionship. The motor-car, he said, had other virtues besides its puff and smell. Mr. S. F. Edge gave "The Sport and Industry," together with the names of the Hon. C. S. Rolls, Messrs. Jarrott and Instone. "The Visitors" was proposed by Mr. E. W. Wells, and responded to by Messrs. T. W. Staple-Firth, P. S. Clay, and E. P. Hooley; and "The Chairman," given by Mr. Booth Granger and acknowledged by Mr. C. Hardy. During the course of the evening it was announced that Mr. Atkey had been obliged, through pressure of business, to tender his resignation as hon. secretary. Mr. E. W. Wells expressed the great appreciation of the members present of the great services he had rendered the club, and presented him with a gold watch value £25, that had been subscribed for by his fellow-members as a token of esteem. Mr. Atkey was carried shoulder-high to the chair, and amidst loud cheers accepted the gift, which he acknowledged with feelingly expressed gratitude.

YORKSHIRE.

THE Yorkshire Automobile Club held its fifth annual dinner on Friday of last week, at the Great Northern Hotel, Leeds. There was a record attendance, and the proceedings were of a very enjoyable character. Mr. A. W. M Bowville, of Bridlington, one of the vice-presidents of the club, took the chair, and was supported by the Lord Mayor of Leeds (Mr. R. Armitage), Messrs. E. Hepper, J. H. Kaye, R. S. Kirk, A. Kirk. H. R. Kirk Harrison Benn, Major Tarry, Arthur Willey, J. Hepper, Dr. Rumboll, L. Hey (hon. treasurer), A. W. Dougall (hon. secretary), H. A. Jones, R. Winn, Norris, Hepworth, Walter Jackson, T. Whitaker, A. Masser, H. A. Routh, T. Atkinson, E. Faiers, F. Marwood, and others. In proposing the toast of "The King," the chairman referred to His Majesty as "the first motoring monarch of Merrie England." The chairman afterwards proposed "Automobilism." He thought the movement had suffered from the inventor. He thought the inventor was rather too much of a specialist; he did not think enough of what had been done in engineering practice in other branches. He had not a sufficiently catholic outlook on the matter. Mr. E. Shrapnell Smith proposed "The Yorkshire Automobile Club." He said that as motoring grew difficulties of organisation were springing up all over the country. He suggested that the best solution of the difficulties would be strong local clubs and county federations. Mr. E. H. Hepper, responding to the toast, said in Leeds there were very few drivers who drove cars at an objectionable speed. It was likely that during the next session of Parliament a Bill would be brought in for the universal lighting of all vehicles. and they as a club. as well as all other road users, would be only too delighted when that Bill was passed. Mr. J. H. Kaye also

Digitized by Google

responded on behalf of the Huddersfield branch. Mr. Rees Jeffreys, in submitting the toast of "The Town and County Authorities of Yorkshire," mentioned that there were more than 200 local authorities in the county having charge of over 13,000 miles of road. He urged that the authorities should combine to abolish the toll gate on Selby Bridge, on the Great North Road. The Lord Mayor of Leeds, in replying to the toast, said that in Leeds very large additions and improvements had been made to the principal streets. He had himself experienced great inconvenience owing to the presence on the roads of slow-moving vehicles without lights. Such vehicles were not only dangerous and disagreeable to automobilists, but also to people who drove horses, and he should be glad to see a universal lighting Bill passed. In conclusion, his Lordship said that although at present he was not an automobilist, he hoped to become one next year. (Applause.) Major Tarry, Chief Constable of Leeds, also replied.

A general meeting of the Club is being held on the 9th inst.

SOUTH-EAST ESSEX.

The South-East Essex Automobile Club held its first annual dinner on Thursday evening, December 1st, at the Alexandra Hotel, Southend-on-Sea, Essex. The chair was occupied by Dr. Silva Jones, one of the pioneer motorists of the district, and a very pleasant evening was passed, aided by the usual toasts and songs.

THE RESPONSIBILITY OF A MOTOR GARAGE PROPRIETOR.

Before Mr. Justice Lawrance and a special jury, in the King's Bench Division, an action has been brought by the Hon. Richard Molyneux, Mayfair, to recover from Mr. E. C. Cresswell, High-street, Newmarket, owner of a garage and repairer of motor-cars, the value of a motor-car which was destroyed by fire whilst in the care of the defendant, alleged to be due to the negligence of the defendant and his servants. The defendant denied negligence and also denied liability. Mr. Duke, K.C., in opening the case, said the plaintiff, through the agency of a friend, the Hon. Mr. Stanley, purchased a car in Paris in June of last year, giving for the car and the accessories the sum of £930. In January of the present year the plaintiff lent the car and the services of his chauffeur to a friend who had a house in the neighbourhood of Newmarket. On the 26th January one of the pumps of the car went wrong, and in consequence the car was taken to the defendant's garage for repairs. On the following day a fire broke out on the defendant's premises, and several cars, including the plaintiff's, were burnt up. The fire was caused by the explosion of petrol vapour, and the plaintiff alleged that the defendant was responsible for the destruction of the car. The plaintiff, his driver, and Mr. E. H. Lancaster having given evidence, Mr. Powell, for the defence, submitted that no negligence had been proved on the part of the defendant, and therefore he was not liable for the damage done. The fact was that the plaintiff's man had dropped some of the petrol from his car, and this was unfortunately fired by the electric hand lamp, which, when an apprentice was about to use it, gave him a shock, upon which he dropped it. It was true that a lamp was taken from the plaintiff's car, and it was after getting that lamp that the petrol fired, the flames spreading and destroying the building, including some eight cars.

During the second day's hearing Mr. Henry Belcher, manager of Humber (Limited), Beeston, said that their works were lighted entirely by gas. In the provinces nearly all garages were illuminated by gas, and it was a general practice to light and extinguish motor-car lamps in the garage. He had also seen open forges in garages where they were used as repair shops. On Tuesday the hearing of the action was concluded. Mr. Ronald Walker, for the plaintiff, having replied on the whole case, his Lordship summed up, and the jury, after an absence of two hours and a quarter, found a verdict for the defendant, for whom judgment was given.

ALLEGED OLD CAR FOR NEW.

The action of the Automobile Components Co., Ltd., v. Lewis came on for trial on Monday before Mr. Justice Ridley and a common jury, in the King's Bench Division. No one appeared for the plaintiffs, and the case was only proceeded with in regard to defendant's counterclaim, defendant being Mr. Corney Lewis, a dentist, of Pontypridd. Mr. Lewis said in August last year, seeing some advertisements about motor-cars, he communicated with the plaintiff company, asking their terms for a small second-hand car. They replied saying they had a new car, absolutely reliable, for £75 12s. He agreed to take it, and paid a deposit of £24, giving bills for the balance. The car was sent in September, but when he received it he found that it was anything but a brand new reliable car. The tyres were worn out, and no thing that could be done would induce the engine to work. He therefore claimed to recover his £24 deposit, £4 12s. for carriage to Cardiff, stalling at 2s. 6d. per week, and other sums amounting to four guineas for expenditure in respect of the car, together with the return of his bills. Mr. Joseph Aylifle, of T. Aylifle and Sons, motor-car manufacturers, of Cardiff, said he examined the car, and found the tyres perished and the machinery unworkable. In the result plaintiff's action was dismissed with costs, no one appearing to support it. On the defendant's counter-claim the jury found a verdict for the defendant, damages £47 5s., with delivery up of the bills. Judgment with costs.

IGNITION.

On Monday Sir Oliver Lodge read a paper on "Ignition as applied to Internal Combustion Engines" before the members of the Automobile and Cycle Engineers' Institute.

Having described the general principles governing the ignition of inflammable gaseous mixtures, Sir Oliver went on to point out that such ignition involved the raising of the mixture to a certain critical temperature locally, and that combustion then spread from this ignition centre. The spreading was influenced by the concentration of the mixture—that was, the proportion of combustible to incombustible molecules, by its state of compression and by its temperature. Since also the molecules of different gases had different rates of motion, the lightest moving fastest, the predominance of the lighter constituent also favoured spread of combustion. In a rich mixture the rate of combustion became so rapid as to be explosive, because many molecules came within the influence of the ignition centre, but in a weak one, owing to the comparative fewness of combustible molecules, the spread of combustion took a meandering course, or might fail altogether. To increase the rate in a weak mixture compression would be resorted to, and it would be fired at several points simultaneously. The speed of combustion was also affected by the contiguity of cold surfaces, such as the walls of the cylinder in a gas-engine; the result was to extinguish the combustion to a certain extent, and there was bound to be some unburnt material. Hence it would be better to work with hot walls, if possible, and he wondered whether a century hence engineers would still be using water-jacketing. The use of hot materials was not outside the possibilities of invention, and the present system seemed a mistake, like that of the Newcomen engine, in which everything was cooled down at each stroke. He proceeded to explain the advances that had been made in the methods of ignition. Some of the older methods were described, and then electrical devices; first magnetos and those using low-tension currents were discussed, as well as those that employed the high-tension current of an induction coil. A method which depended on inserting in the circuit a pair of Leyden jars, the spark from the outer coatings of which was employed to fire the mixture in the cylinders, was also described. This arrangement had the advantage that short-circuiting was impossible, and that the spark was not affected by moisture—indeed, would actually pass under water.

CASE DISMISSED.

Mr. Alfred Hutchinson, motor-car driver to Sir W. G. Armstrong, Whitworth and Company, was summoned at the Bow Street Police Court on the 2nd inst. for that he did unlawfully use a certain motor-car for a period of one hour after sunset and one hour before sunrise on which there was not kept burning a lamp so contrived as to illuminate and render easily distinguishable the letter and figures on the identification plate fixed on the back of the said motor-car. Evidence was given by two policemen. One stated that upon receiving a signal from another policeman he flashed his light to the driver to stop and the driver stopped. Both policemen admitted on cross-examination by Mr. Staplee Firth that the lamp was burning brightly, but that it was fixed too high up. Mr. Worby Beaumont gave evidence for the defence and stated that he had examined the lamp in the position in which it was fixed. Mr. E. Gascoine also gave evidence, and ultimately Mr. Fenwick dismissed the case, stating that he considered that as there was a doubt he would give the defendant the benefit of it.

CASES AGAINST MOTORISTS.

Place.	Summoned for	Fine.
Bradford	Driving without a licence	5s.
Birmingham	Using unregistered motor-cycle	Dismissed on payment of costs.
Marylebone	Driving unregistered car	£5, etc.
Bromley	Keeping motor-carriage without licence	10s.
,, ...	Driving dangerously	£1, etc.
Ayr	Failing to stop when signalled to	£1, etc.
Brighton	Dangerous speed	£5, etc.
Thames	Keeping motor-car without licence	1s., etc.
West London.....	Allowing motor-car to travel backwards for a greater distance than necessary.	3s., etc.
Lambeth	Dangerous driving	£3, etc.

A motor lifeboat will be stationed at Newhaven for the winter.

THE

Motor-Car Journal.

VOL. VI.] LONDON, SATURDAY, DECEMBER 17, 1904. [No. 302.

Published Weekly by CORDINGLEY & CO., 39 & 40, Shoe Lane, London, E.C.

COMMENTS.

ALREADY the central political organisations of the principal parties in the House of Commons are tabulating the owners of automobiles belonging to their particular political faith—or at least, such as have expressed their willingness to lend their vehicles for the purpose of bringing voters to the poll at the general election. At the bye-elections the motor cars have proved a greater factor than they are likely to be in the general contest, for the simple reason that concentration upon any one constituency will not be possible. When it was found—before the last reform of the law relating to elections—that the cost of carriages by single candidates was running into hundreds of pounds, Lord James of Hereford secured a provision for more polling-places and the abolition of the direct hiring of carriages. Now the latter have to be lent, and just as voters were getting used to walking to the poll, the motor-car has come along, disturbing all the notions of political agents. For the voter wants a ride in a motor-car and some, more obstinate than others, have declined to vote unless such provision was afforded. Should they be equally intractable when the general election takes place, a new terror will have been added to the difficulties of the political agent.

◆ ◆ ◆

An Exception.

THERE are, of course, a few discordant chords in the chorus that favours the use of the automobile for electioneering purposes So far as Sir Henry Aubrey-Fletcher is concerned, little electioneering is likely to be done by motor-car in his division of Sussex. Sir Henry assisted in the recent Horsham fight, and there, in his own words, they had "the screeching, howling noise and smell of motor-cars dashing through the villages day and night." Speaking at the annual fete of Worthing Primrose Leaguers last week, Sir Henry said he thought he could promise them one thing—they would never see him dashing about in a motor-car. He would sooner go to any exertion, wear out horse after horse, and tramp miles on foot about his constituency, than go about in a motor-car. Really!

◆ ◆ ◆

Mr. Balfour as Motorist.

WITH this issue we give as a Supplement an interesting picture, showing the Rt. Hon. A. J. Balfour just returning from a motor-car trip to his official residence, No. 10, Downing Street, London. The interest of the Premier in the automobile movement is no new thing; it began in the days when Dashwood Hill contests were a feature in the motor car year, and we remember the famous occasion in 1902 when Mr. Balfour mounted the hill on a 40-h.p. Mercedes—Mr. Campbell Muir driving—in 1 min. 13 sec. Since then he has become an enthusiastic motorist, making many long journeys by car, and in other ways showing how closely he follows the movement. The Premier not only regards the motor-car as a means of pleasure; he sees in it some help to the solution of many of the modern difficulties associated with the congested populations of our great towns.

Motor Experts on the Bench.

LAST week we referred to the innovation on the part of Judge Addison, K.C., at the Southwark County Court, in having a motor expert sitting with him in order to secure proper guidance during the hearing of a case involving automobile technicalities. Soon after we went to press judgment was given, when his Honour complimented the legal gentlemen on the trouble they had taken, expressing his astonishment at the great amount of technical knowledge displayed. During the hearing the expert, he said, was necessary, because of the want of technical knowledge in the court, and if judges only had the courage to appoint advisers in similar cases an enormous amount of time and contradiction would be saved. When it came to the question of the payment of the expert's fees, the judge suggested that the parties in the case should share. The defendant, who won the action, claimed, however, that the expert was necessary solely as the result of the plaintiff's alleged breach of contract. Judge Addison controverted this with the modest suggestion that it was his own want of special knowledge that made the expert's services necessary, and the point has been referred to the Registrar for settlement. Apparently in cases where such assistance is to be called into requisition each party should, according to the Judge of the Southwark County Court, bear a moiety of the expense.

◆ ◆ ◆

Seaside Races.

MOTORISTS will be very busy next year in connection with the many motor car meets and races that are being organised at English sea-side resorts. The secretary of the Yorkshire Club, for instance, has just received from the district council of Filey a letter sanctioning the holding of speed trials by the Club on the sands at that growing place. Blackpool, too, will have speed trials, somewhat similar to those which recently took place. The Southport Corporation is anxious that that town shall not be ignored. The Lincolnshire Club promise a meet at Skegness, the South Wales and Monmouthshire organisation will hold a race gathering at Port Talbot, and another gymkhana at Hastings is also in contemplation. Should Bexhill, Eastbourne, and two or three other towns which have always shown some partiality for such gatherings decide to invite motorists again, it is evident that the holiday period of the year will be largely filled, so far as motorists interested in racing are concerned.

◆ ◆ ◆

Warnings in Surrey.

MOTORISTS touring in unfamiliar places have frequently come to danger when the presence of a notice warning them of the steep decline or the narrow sharp turning would have saved bad accidents. Dye House Hill, at Thursley, near Godalming, is a case in point. Several accidents have occurred there, and the corner is one of considerable danger to all users of the road. Attempts to induce various organisations and authorities to put up a warning board having failed, Mr. C. Cordingley has, at length, persuaded the Hambledon Rural District Council to erect the necessary boards at his expense, and thus motorists will, in future, have due warning when nearing that particular spot.

A Ten Guinea Tax.

THE members of the Berks and Oxon Chamber of Agriculture are doubtless very reasonable persons in their individual capacity, but when they appear in all the glory of their collective importance they become somewhat one-sided in view and irrational in judgment. At their last meeting Mr. W. J. Henman proposed, Mr. A. Simmons seconded, and the meeting endorsed a resolution to the effect "that a tax of not less than £10 10s. a year be imposed on cars of four wheels or more, and that cars with two wheels pay £5 5s. per annum, in addition to the existing licences, the money to go to the County Highways fund in order to prevent as far as possible damage to the roads and the dust nuisance." An amendment was moved, but it was of nearly as drastic a character, so that automobiles were practically without advocates in the gathering. But surely Mr. Henman and his friends will, upon reflection, see how such a proposition would seriously prejudice a growing industry if it stood any chance of adoption—which it certainly does not.

◆ ◆ ◆

A Lady Automobilist.

THE Hon. Mrs. Maurice Gifford, whose portrait we reproduce, is one of the best-known lady automobilists in Lincolnshire. She runs a 12-h.p. Sunbeam, and is an expert driver, always steering her own car. On one occasion this year she and her husband took part in a driving competition promoted by the Lincolnshire Club in Grimsthorpe Park, when

The Hon. Mrs. Maurice Gifford on her Sunbeam Car.

she demonstrated her skill in driving by steering the car to victory. Not only is the Hon. Mrs. Gifford a keen automobilist, but she is an ardent follower of other sports and pastimes. Her favourite occupation in winter is hunting. Both she and her husband are strong supporters of the automobile movement in Lincolnshire, and once during the past season they organised a club meet at Boothby Hall, their place near Grantham, where a novel driving competition for the delectation of the members took place.

◆ ◆ ◆

Education needed in Wales.

AT Newport (Mon.) is a Chamber of Commerce, some of the members of which need education with regard to equine and automobile matters. Mr. H. Williams raised the question at the last meeting of the reduction of the maximum speed of motor vehicles passing through the district, and moved a resolution approving of the idea. This was agreed to with unanimity, some being of opinion that motor-cars were dangerous things. One speaker declared, in a tone of sweet reasonableness, that they were "like the infernal regions on wheels," a style of phrasing that certainly did credit to his powers of expression. On the same day a gentleman was riding a horse in Cardiff when the animal stumbled and crushed a woman carrying a baby, who was near, against the wall of a railway arch so severely that the infant's life is despaired of. Accidents with horses are more frequent than many people imagine, but, unless they are unusually serious, they rarely find their way into the papers. Why does not the Newport Chamber of Commerce concern itself with such dangers of the streets instead of adopting a minatory attitude towards a form of locomotion that will do much for commerce and business the welfare of which such an association exists to promote?

◆ ◆ ◆

The Economy of the Car.

BEFORE the members of the London Institution the Hon. C. S. Rolls has been lecturing on the development of motor traffic, and, with the aid of lantern slides, showing its advance during the last century. In the course of the address he said that the time was well-nigh ripe when the public would be able to purchase a small, simple, reliable car for £100 to £150 that would carry three persons and travel at the rate of twenty or twenty-five miles an hour. When the price of motor-cars came within the reach of the less moneyed classes, people whose work was in towns would be able to live in the country, instead of clustering as they now do around railway stations or tramway routes. The lack of success in connection with the tradesman's light delivery van had been owing to makers using the standard mechanism of their pleasure vehicles instead of designing special frames to carry the loads. Touching upon the transport of heavy goods, Mr. Rolls mentioned that a ton of goods could be carried forty miles for 5s. 6d. without any changing or handling of the goods from the start to the place of destination.

◆ ◆ ◆

Branding Motorists.

ACCORDING to Mr. F. W. Verney it would be well if motorists convicted of furious driving were to be compelled thereafter to have their cars painted yellow and marked with the Government broad arrow. We are almost surprised at the modesty of Mr. Verney, who has thus been giving ideas to the Buckinghamshire Chamber of Agriculture. Why not return to an earlier method of branding the individual, so that wherever he was he should be known and recognised as a very undesirable person? Ere motoring became popular ordinary mortals had a proper dread of conviction in the police-court; but, thanks to the travesties of justice that have been played by magistrates and police on many a country bench, the respect for the impartiality of the law has been greatly minimised since the Motor Car Act came into operation.

◆ ◆ ◆

Provincial Instruction.

SEVERAL owners of automobiles in the town of Warrington recently asked the Corporation to organise a class at the local Technical Schools for instruction in the theory, structure, and management of motor-cars, similar to those that are already in successful operation in the Metropolis. The authorities, however, could not see their way to accede to the request, whereupon the directors of Messrs. Joseph Crosfield and Son, Limited, resolved to hold the class in the Works' Assembly Room from 2.30 to 3.30 each Thursday afternoon. The attendance promises to reach or exceed thirty. At first sight it would seem somewhat extraordinary for a firm in no wise connected with the motor industry to adopt this course, but Messrs. Crosfield have always shown considerable public spirit with regard to such matters, and would like, through our columns, to thank the leading motor manufacturers and agents in this country for the kind way in which they have responded to requests for details regarding their special manufactures. In many cases these firms have not only sent their catalogues and driving manuals, but they have

Digitized by Google

sent photographs, lantern slides, and specimens of their material, and anything and everything which they thought was likely to prove of interest to members of the class.

◆ ◆ ◆

English Drivers in Ireland.

FROM a case which was heard in a Dublin police court the other day, it would appear that English motor-car drivers do not like Dublin any more than did the Rev. Robert Spalding appreciate London. The driver of a motor-lorry, belonging to the Leinster Paper Company of Clondalkin, was summoned for driving the vehicle without a licence. The company was also hauled before the magistrate for employing an unlicensed driver. At the court it was explained that they had previously had many licensed drivers in their employ, but they had left after a while to return to England. So before obtaining licences for any more drivers, they had decided to make sure they were likely to stay and thus avoid unnecessary expense. Under the circumstances the idea was probably one that appealed to common sense, but it contravened the legal position, so the owners of the motor-lorry and their driver were both dismissed with cautions and costs. The magistrate said that the company could not be allowed to train men at the expense of the public. "That," he said, "might mean a great many broken bones." We did not know before that there was any connection between licences and efficiency; perhaps Mr. Drury, the magistrate who thus illuminated his judgment with legal wisdom, will explain?

◆ ◆ ◆

Agriculturists v. Motor-cars.

THE Staffordshire Chamber of Agriculture, meeting at Stafford on Saturday, passed a resolution urging the Central Chamber and local authorities to take measures to ensure more stringent restrictions for the protection of the ordinary users of the roads against motorists. A strong protest was entered against wealthy men being allowed to race about the country for their pleasure without regard to the convenience and safety of the general population. A special ground of complaint was that the drivers employed were in the main ignorant and careless with respect to horses. Such generalisations, while sustaining public prejudice against motor-cars, do not carry us much nearer the solution of the problem. Agriculturists should remember the old antipathy of their class against railways in the early Victorian days and recognise how completely they have had to change their views.

A Reminiscence of the Military Manœuvres in East Anglia.—A De Dion Car in the Field.

◆ ◆ ◆

Motor Fire-Engines.

LAST week the Fire Brigade Committee of the London County Council recommended that tenders be invited for the supply of a motor steam fire-engine. Sir M. Beachcroft asked the Chairman of the Committee if he considered that motor traction was satisfactorily adaptable to fire-engines. Mr. E. Smith replied that the motor-engine already in the possession of the brigade had been fairly satisfactory. There were, however, things about such vehicles which rendered them less reliable than engines drawn by horses. The committee were watching every invention in that form of traction and its adaptability to fire-brigade purposes, and they hoped to make a fuller report in due course. At present, however, they could not entirely rely on motor fire-engines. The recommendation was adopted, and we hope the result will justify the committee in their experiment.

◆ ◆ ◆

An Expensive Little Trip.

AN amusing incident is related regarding a deputation consisting of the Chief of the Greenock Police, an ex-Bailie, and a motor-car mechanic, who recently visited Glasgow. They journeyed to the city for the purpose of weighing one of the vehicles which were then being used by the West of Scotland Carrying Company, Limited, in their motor carrying service between Glasgow and Greenock. On arrival at the company's works, it was pointed out to them that the warrant did not compel the company to place the vehicle on the weigh-bridge, and that the visitors would require to do this for themselves. The mechanic, who had been taken up from Greenock, then boarded the car, but in taking it through the work gates he drove the motor into the wall, of which a large portion was knocked away. He reversed the car, and it then ran across the roadway and damaged the wall on the opposite side, besides breaking a plate-glass window. A constable is reported to have come upon the scene at this juncture and demanded to see the driver's licence. This little matter had apparently been overlooked, and the officer thereupon took the names and addresses of the trio. It is believed that the damages consequent on the little outing will amount to considerably over £100.

◆ ◆ ◆

Indian Progress.

CONSIDERABLE interest attaches to the outlook for automobiles in India by reason of the forthcoming trials and competitions to be held there, and which are attracting international attention. From a French commercial journal we learn that only five years have elapsed since the introduction of motor-cars into India; there are now about 150 in the country, mainly in a few of the larger towns and in the capitals of some native States. The practical advantages to be derived from automobiles are as yet by no means appreciated; the European or native purchasers treat them as toys, available for short spins, but useless for long journeys. The chief reason for this is the lack of mechanics, drivers, and repairing shops. In spite of these drawbacks, the importation shows a steady increase; a considerable development of the trade might therefore be confidently expected to result from the establishment of garages with repairing shops attached, in such towns as Calcutta, Bombay, and Madras. It has often been suggested that automobile services

Digitized by Google

should be established in connection with existing railways; but hitherto such schemes have fallen through owing to the existence of difficulties which these establishments would obviate. The demand for very fast cars is said to be small, an average speed of about eighteen miles an hour being held to be sufficient in most cases.

◆ ◆ ◆

In the New Forest.

As in Ireland, animals have the right to sleep on the highway in the New Forest, and should an automobile happen to pass over their bodies, the owners pour forth all manner of threatenings against the motorists. Of course, the local owners of motor-cars are not the delinquents; at the New Forest Verderers' Court held at Lyndhurst it has just been asserted that such things are done "by the people who came from London on a Saturday night, and then went so fast that it was utterly impossible to stop them or know who they were." That cattle in the New Forest have been killed by motorists is apparently clear, and, although the drivers have no legal responsibility in the matter, it is satisfactory to learn that they are starting a fund from which to help commoners whose animals are destroyed in motor-car accidents. This, however, must not be regarded by motorists as condoning, in any way, furious driving through the New Forest, where every care should be taken to propitiate public opinion, and not to arouse ill-feeling.

The above Illustration shows the method adopted in the recent Vanderbilt Cup Race for rapidly Refilling the Petrol Tanks of the Competing Cars.

◆ ◆ ◆

Free Navigation for Motor-Boats.

Those interested in the development of the motor-boat movement in this country should watch with close attention the assistance which the authorities in France are giving to the progress of the sport. The Minister of Public Works in Paris has decreed that all pleasure-boats under ten tons having a mechanical motor are to have a free passage through the locks on the Marne between Charenton and Epernay. This removes the difficulties which owners of motor-boats have frequently experienced at the hands of lock officials. The same privilege is to be extended to all the locks on the Seine and other rivers and canals, and in a short time motor-boats, it is expected, will have free navigation through all the rivers in France.

Removal in the New Year.

Early in the new year the offices of *The Motor-Car Journal* will be removed from Shoe Lane to 27, 29, 31, and 33, Charing Cross Road—a new building of splendid frontage, large dimensions, and ample accommodation for automobile firms anxious to be conveniently near the chief avenues of the West End. We shall make a definite announcement as to the date of removal in an early issue; meanwhile this preliminary notice is made for the benefit of those who have lately seen *The Motor-Car Journal* sign in the windows of its future home, 27–33, Charing Cross Road, London, W.C.

◆ ◆ ◆

The Universal Lighting of Vehicles.

On Tuesday an important deputation was received at the Home Office by the Hon. T. H. Cochrane, Under Secretary of State for that Department. On another page we give the memorandum which had been prepared by the Motor Union on the subject, and in introducing the deputation the Hon. A. Stanley, M.P., said everybody admitted the anomalies and inconsistencies of the present lighting by-laws. The best way to amend them would be by legislation introduced by some member of Parliament, but in the present condition of affairs in the House of Commons no private member's bill would stand much chance of success. Dr. Boverton Redwood suggested that, pending the passing of a bill through Parliament, the Home Office should take action in the direction of endeavouring to secure that local authorities should adopt a by-law requiring the carrying of a front light and a rear red light, without any exemption of slow-moving vehicles. Colonel Crompton also spoke, and in reply Mr. Cochrane remarked that there was much force in pointing out the anomaly that the swift vehicle must carry a rear red light while the slow-moving one was exempt.

◆ ◆ ◆

Legislation wanted.

He promised that if a private member of Parliament would introduce a bill into the Commons embodying the views of the deputation no opposition would be encountered from the Home Office, an expression of opinion that should lead to a prompt response on the part of some M.P. anxious to increase the safety of our public highways. He also assured his hearers that should local authorities in future suggest by-laws containing exemptions from carrying lights for certain classes of vehicles, the Home Office would seriously consider whether such be sanctioned. There was no doubt that the best solution of the difficulty would be a uniform law for the whole country; and in that direction legislation must make an early move. Having regard to the practical acquaintance of many members of the Cabinet with automobilism, there should be little difficulty in securing the passage of such a measure as is suggested.

◆ ◆ ◆

Cornish Wisdom.

When the shortsighted people of Helston adopted a stubborn attitude towards the motor-'bus service of the Great Western Railway Company other councils learned wisdom. A discussion on the injury alleged, or supposed to have been inflicted on the roads of St. German's by the presence of such 'buses in that district has taken place at the local district council, when the advisability of caution in denouncing the company was advocated. The surveyor said the motor-'buses had come on them like a meteor, and they were not prepared to receive them. His own impression was that engineers and highway surveyors would have to find another method of macadamising and making up the roads, or they would sustain tremendous damage. In the dry weather the cars turned up the dust, and in the wet weather they took up the mud. He believed it would come to this, that they would be obliged to pave their roads in the middle for the cars. Evidently the lesson of the Helston obstinacy has been recognised in other districts of Cornwall.

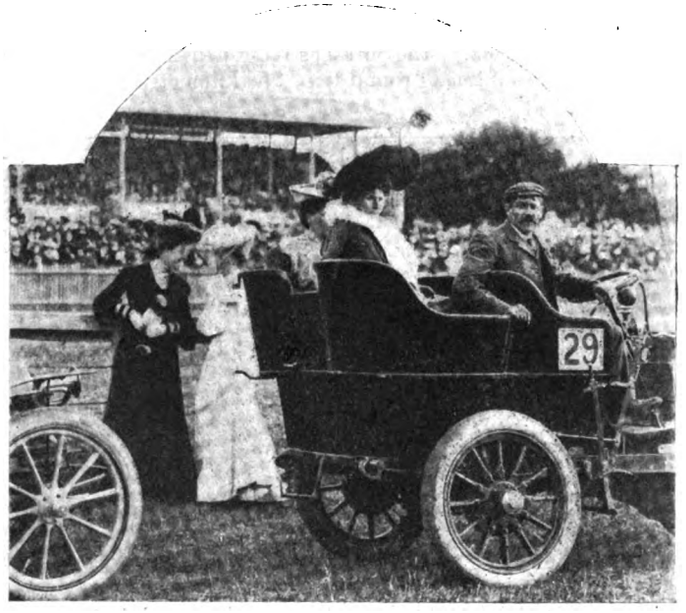
AUTOMOBILISM IN 1904.

REVIEWING the course of the automobile movement during the past year, we may surely declare it to have been a period of steady advance. The motor-vehicle has not merely effected one or two changes; it is transforming social conditions, and is likely to prove useful in the solution of some of the pressing grievances of the time. That it has received recognition from every class and every section is but a truism; the fact is that the Motor-Car has been given a permanent place in our industries, and is now a recognised factor in national life.



During 1904 the columns of the *Journal* have recorded the advance of the automobile in Royal favour. Our own King often goes from his palace in London to the Castle at Windsor by motor-car; the King of Portugal enjoyed the delight of motoring during his recent visit to England; the young King of Spain has defied the wishes of his Court, and persists in driving his own car; and in Italy, Belgium, Germany, and elsewhere the highest in those lands have bestowed marks of favour or have publicly identified themselves with the automobile movement. Equally gratifying has been the patronage of the chief personages in republican countries like France and the United States.

Looking at home, and glancing through our own columns for the past year, it may be recalled that we have recorded the march of the automobile in military esteem, its growing use by municipalities for street cleansing, the extension of public motor services by railway and 'bus companies, the use of the motor-car by bishops in pastoral visitation, the notable tour of General Booth, and the sanction of motor-cars as part of the necessary equipment of their officials by municipal and local authorities—all such developments are evidences of the invasion of the car into most conservative aspects of affairs. But in any backward glance everything is overshadowed by the fact that this year motorists have been subject to the pains and penalties associated with the operation of the Motor Car Act, the passage of which through the Houses of Parliament occasioned so much agitation and discussion in the later months of 1903. For the first time in our history private gentlemen have had their vehicles numbered like auction lots, and they have been at the mercy of local prejudice, police watchfulness, and magisterial bigotry. Those who hoped that the new Act would prove a satisfactory solution of the difficulties that had arisen in connection with the advance of the automobile movement have been grievously disappointed, and the many anomalies that have been discovered during the course of the year have shown that the contention of those motorists who were loth to welcome fresh legislation has been amply justified.

It was said that when the new Act came into operation police traps would no longer be employed to snare motorists, but experience has proved to the contrary. Anxious to propitiate rural councillors and bucolic grandees who, on village green and around the tables of the parish conclaves, denounce the coming and the going of the automobile, constabulary officers delight in devising ingenious plans wherewith to waylay motorists. In recent years the poacher, the marauder on the roadside, the petty tyrant of the hamlet, and similar persons of nefarious habits, were the objects of the policeman's quest. He was the terror of the evil-doer, the pursuer of the wicked one, and the most respected functionary in the village. Now, in some districts of the south, his calling has been degraded, and the unmanly system of espionage which he has had to practise upon motorists has led him to be despised, and, in constables of the better type, to despise himself.

Of course the police traps are not always devised and controlled by men in uniform. Plain clothes officers have been enlisted in the ranks of the motor-trappers, and these, lurking behind hedgerows, hiding in pig styes, secluding themselves in barns, and demeaning themselves in other ways, have become frequent sights on some of the southern main roads. Two or three men stand idly at a corner—probably a cross-road. They appear innocent indeed, lounging and smoking as though they were mere loafers—a habit, by the way, soon acquired by men who have to set traps to catch other men, and who conceive it their duty to give evidence of some kind or other, without the limitations that would be imposed by a strict sense of accuracy. And yet, when tackled by motorists who alight from their cars to view the scene, these men do not seem to appreciate their position. They are not entirely hopeless; but surely their superior officers must feel it is derogatory to the status of the police that they should be called upon to do such work.

Unfortunately the matter does not end there. There is little doubt that grave errors have taken place in the courts during recent months as a result of the keen desire of the police to secure convictions, regardless of truth or anything else of such a character. They know that the magistrates before whom they appear are invariably prejudiced, that their evidence will not be too closely sifted, and that the views of the presiding "justice" will probably be against the motorist. Can it be wondered that the motorist of to-day regards justice as a bye-word and equity on the bench as something which was, and is not now? Given a large amount of local prejudice, a constable always in association with those who foster such a condition of mind, and a magistrate full of a desire to air his pompous state against strangers of position, and the result is clear. Every week

At an Australian Motor Gymkhana.

during the year we have recorded quite a score of cases in which motorists have been convicted under the Act—a few dismissals have also been reported. Space has prevented the publication of all the cases which have occurred, but those made known to our readers have been sufficiently numerous, and distributed over an area wide enough, to convince any impartial reader that persecution rather than prosecution has been the order of the day.

It must be confessed that the feeling of fairness which was once associated with our legal procedure has had a shock during the year now closing. There is no guarantee of impartiality where motorists are concerned, and the uncertain reading of some clauses in the Act is another contributory factor to the present the state of affairs. Until the whole position is reviewed again at end of 1906 things will continue as now, unless, in the meanwhile, influence is exercised with county councillors and others to induce them to make the police feel the need of exercising reason in their imaginative moods and of bringing common sense to bear in the issue of summonses.

IN the recent successful 4,000 miles trial Messrs. S. Bowley and Son's "Special" motor spirit was used throughout and gave every satisfaction This "Special" brand has merits for reliability, efficiency, and economy.

CONTINENTAL NOTES.

A Public Service in Russia.

The "Journal de St. Pétersbourg" states that a project is under consideration for running an automobile service between Novorossisk and Sukhum by way of the Black Sea coast. The scheme, which is strongly supported by the local authorities and landowners, should prove of great benefit to the Caucasus, some parts of which are destitute of a postal service. There are, however, many difficulties in the way owing to the poor condition of the roads throughout a large portion of the route.

The French Carburettor Competition.

The Technical Committee of the French Automobile Club has just made the awards in respect of the competition of carburettors for special motors. Longuemare secures the gold medal for petrol carburettors for 8-9-h.p. De Dion engines; Claudel for a paraffin carburettor for the same motor, and Gautreau a bronze medal for a heavy oil carburettor for the Gautreau engine.

Motor Boat Racing on the Seine.

The motor-boat race known as "La Coupe du Salon" is to be held on Sunday next. The course is from the Alexander III. Bridge, near the Exhibition, to the Suresnes Weir, a distance of 12½ kiloms. each way, making the round trip 25 kilometres. The racing craft will cover the circuit four times—total distance 100 kiloms.; the big cruisers twice, equal to 50 kiloms., and the small boats once. The boats will be started in batches of three. The entries are about 80 in number, and include many of the boats which have competed in the leading events of the last season.

A French Motor Union.

A "Ligue des Chauffeurs" has just been formed in Paris to defend the interests of motorists. A committee has been appointed to draw up the necessary rules and regulations.

A Rouen-Trouville Motor-Boat Race.

The new French daily "Les Sports" proposes to organise a motor-boat race from Rouen to Trouville during next season. It is suggested that the competing boats should assemble on the river in Paris, and, after a fête in the Bois de Boulogne, promenade down the Seine as far as Rouen. A big water fête is to be held at the latter place prior to the start the following day for the race proper.

The Paul Meyan Cup.

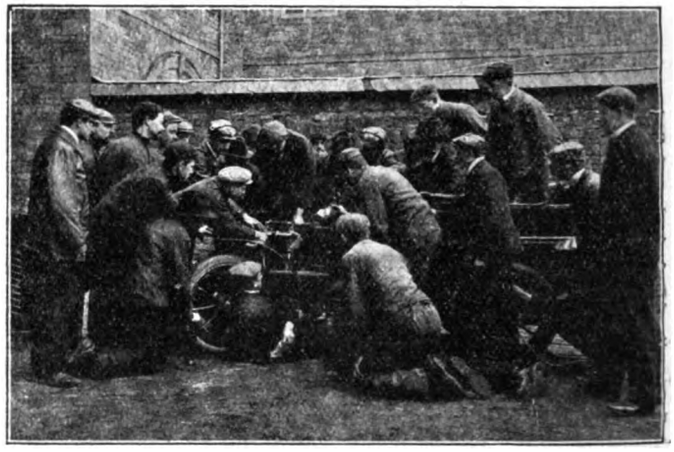
The Club Nautique de Nice has fixed April 18th, 1905, as the date for the motor-boat race for the Paul Meyan Cup, at present held by "Vas-y," belonging to M. A. Jean. The race, which has to be won two years in succession to secure the cup outright, is for boats up to 12 metres in length, and is over a 100 kilometre course. All entries should be sent to the club, whose address is 93, Quai du Midi, Nice. The list will close twenty days before the race.

Motor-Boat Racing in Germany.

June 29th and 30th next year are the dates provisionally fixed by the German Automobile Club for its motor-boat meeting at Kiel. The first day will be devoted to short races, while on the second there will be a competitive run from Kiel to Travemünde.

Another Steam Car for the Shah.

The attraction at the stand of the Gardner-Serpollet Company at the *Salon* is a 9-h.p. two-seated steam car for the Shah of Persia. This is gorgeously upholstered in damask and decorated all over, even to the lamps, with tassels hanging from the sides of the seats. This makes the sixth car M. Serpollet has supplied to the Shah.



An International Conference.

A conference of the International Association of Automobile Clubs was held at the A.C.F. club-house in Paris on Monday. Eighteen delegates attended, Great Britain being represented by Sir David Salomons, Colonel Holden, and Mr. Alfred Bird. Especial importance attached to the meeting owing to the fact that several points bearing on the Gordon Bennett Cup race were discussed. As a result of the conference, it may now be stated that the 1905 race will be run under the same regulations as this year. The proposals for reducing the weight-limit of cars, for a team contest, for a two days' race over 1,000 kilomètres, and for allowing only a fixed number of tyres to competitors, were dropped. It was decided that the annual contest should always be held in the last week of June, or as nearly as possible to that date. After a long discussion, the classification of cars by weight already established was officially adopted for all countries except Belgium, which accepted it only provisionally. In future, the term "heavy car" will mean a vehicle weighing over 650 kilos and a "light car" one under that figure, while the limit for motor-cycles is fixed at fifty kilos. Other decisions arrived at by the conference were that only one club in every country will in future be officially recognised, that danger and caution signals shall be blue and yellow, instead of red and green, and that due notice of all sporting events shall be given by each club to all the others to avoid clashing. A proposal to appoint an international commission for all sporting events was shelved, and another to create an international sign to be carried on motor-cars for the purpose of identifying law-breakers was dropped as being impracticable.

The Gordon Bennett Cup Race.

Although the course has not yet been decided upon, the entries for the French eliminating trials have already assumed

What is stated to be the first Automobile School in Germany has lately been organised in connection with the Technikum at Aschaffenburg, Bavaria. The illustrations given above show the students being taught how to steer and to deal with engine troubles, respectively.

Digitized by Google

imposing proportions. Seventeen firms have stated their intention of entering forty-four cars, as follow :—

Makers.	Cars.	H.p.	Makers.	Cars.	H.p.
Richard Brasier	3	110	Turcat-Méry.....	3	120
Mors	3	130	Clement-Bayard	3	120
De Dietrich	3	120	Hotchkiss.....	3	150
Darracq.....	3	140	Gardner-Serpollet	3	—
Gobron-Brillie ...	3	150	Delaunay-Belleville	2	120
Renault.....	3	90	Berliet	2	130
La Buire	2	120	Boyer.....	2	120
Rochet-Schneider	2	120	Brouhot.....	1	80
Panhard.....	3	120			

It is also reported that vehicles will be entered by Corre, C.G.V., Cornilleau, and Westinghouse. It is further stated that the A.C.F. has decided on passing some radical rules regarding the eliminating trials. It is to be laid down that not more than three cars, not only from one factory but of one type, may run. For instance, under the new order of things it would not be possible to run three Turcat-Mérys and a trio of De Diétrichs, because the last-named are made under licence from the former. The new regulation aims at the recognition of the fact that the design of an engine and car is equally important with its actual manufacture. The nationality of the drivers has also been considered, it being decided that none shall take part in the race who have not been domiciled in France at least two years.

◆ ◆ ◆

Switzerland and the Cup Race.

Messrs. Dufaux, who, it will be remembered, built a car for the 1904 race, but which did not start owing to an accident to the steering gear, are reported to have decided to build three 100-h.p. vehicles for the 1905 event.

◆ ◆ ◆

A New Liquid Fuel for Steam Cars.

On Thursday last week the Serpollet Company submitted one of their steam cars to a run from Paris to Rouen and back, the object being to demonstrate the possibility of using a new cheap heavy oil derived from coal-tar. M. Serpollet obtains the raw material from gas-works, and by subjecting it to a purifying operation, and by making certain additions to render it homogeneous, secures a liquid fuel which not only gives good results in the generator burner, but also shows a noteworthy economy in cost.

◆ ◆ ◆

Motor Prison Vans.

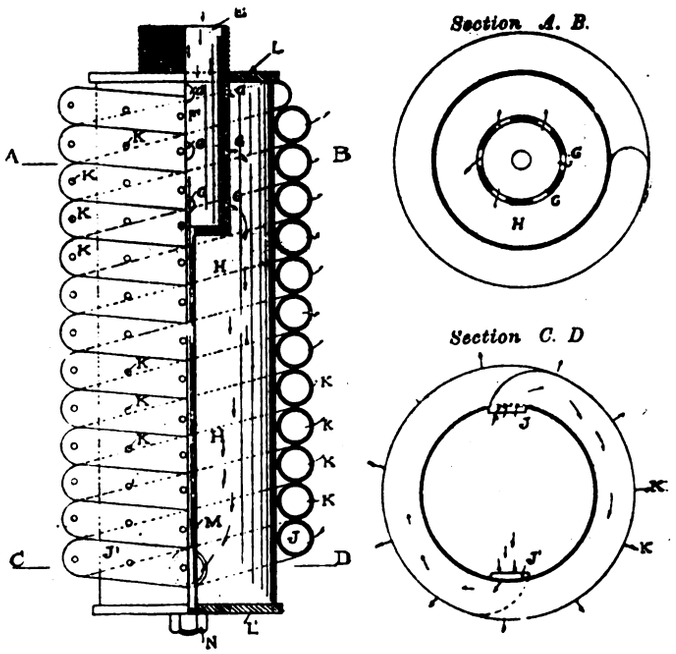
Motor-cars are already used for a variety of purposes in Paris. Quite a number of electric vans are used by the postal authorities Motor dust-carts have lately made their appearance, while now it is proposed to introduce automobile prison vans.

◆ ◆ ◆

A New Mercedes Car.

A new 70-h.p. Mercedes car was seen for the first time in Paris on Monday. The inlet valves are on the side of the cylinders instead of on the top and the cam shaf gear wheels are enclosed. The differential is separate from the change-speed gear, and on the differential shaft there is a ratchet and pawl sprag which immediately comes into operation should the car commence to run back on a hill. The other distinguishing feature is that the supply of gas is cut down when the clutch is thrown out by a lever working in connection with the clutch pedal.

Messrs. Perman and Company, Limited, has been registered with a capital of £6,000 to carry on, among other things, the business of agents for and dealers in motor-cars. The first directors are Messrs. G. Alston, R. O. Smith, and T. H. Wright.



The Brighton and South Coast Motor Garages, Limited, is the title of a company registered with a capital of £15,000 to establish agencies for the sale and purchase of motor-cars and vehicles, and to carry on the business of garage proprietors, motor and carriage dealers, etc. The first directors are Messrs. R. K. Moore, D'Arcy R. Baker, and V. H. Miller, and the registered office is at 18, Fleet Street, E.C.

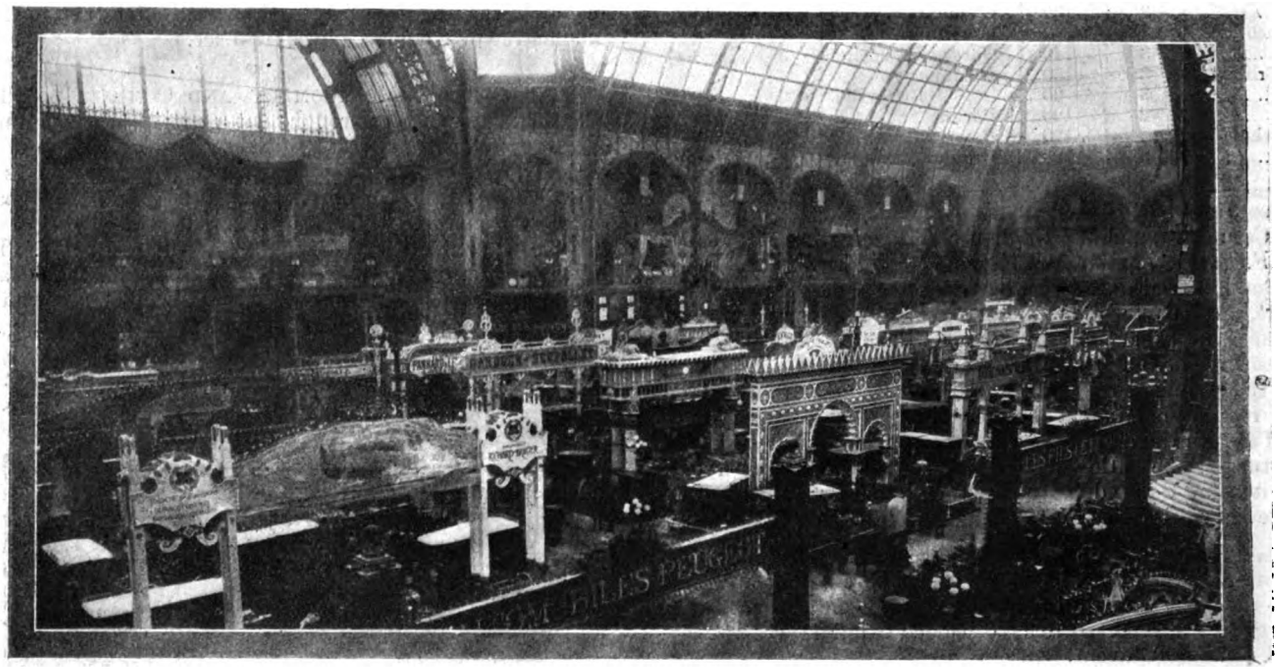
MOTOR CYCLING NEWS.

New world's motor-bicycle records for the hour and the 100 kilometres (62½ miles) were established by Anzani, on the Parc des Princes track, in Paris, last week. Riding an Alcyon machine with Buchet motor, he succeeded in covering a distance of no less than 55 miles in the hour, and traversed the 100 kilometres in 1 hour 8 min. 24 3-5 sec.

◆ ◆ ◆

Messrs. W. Montgomery and Company, of Bury St. Edmunds, have lately brought out a new silencer for the engines of motor-cycles. Referring to the accompanying detail drawings of the device, which is known as the Montgomery, E is the inlet to the silencer, the exhaust gases passing into the chamber F, where the charge is broken up and gets away by means of holes G into the outer chamber H, as shown by arrows. The force of the explosion carries the charge to the end of chamber H, whence it escapes into the coils J and J', which are wound round the outside of the chamber H, from end to end, in the form of a

double spiral, the ends projecting slightly into the chamber H. The gas passes through the coil and emerges into the open air by means of the small holes K drilled in the coils throughout their length. L and L' are circular end plates grooved to receive the cylindrical chamber H, the whole being held in position by means of a central pin M and nut N, so that the silencer can be readily opened out for cleaning purposes. It is claimed for the apparatus that not only does it effectively silence the exhaust but that, by its use, the power of the engine is increased, there being no baffle plates to cause back pressure.



◆ ◆ ◆

The Motor-Cycling Club is of the opinion that there should be a central organisation of motor-cyclists which should not be subordinate to the A.C.G.B.I., and is inviting the many provincial motor-cycling clubs to express their views on the point. The Motor-Cycling Club has no antagonism to the Auto-Cycle Club, but believes that the pastime could be placed on a more dignified basis by an organisation in which all the clubs should be represented. Its annual dinner was held on Saturday last, with Mr. S. F. Edge in the chair.

The Ordnance Survey have published a cheap map of Yorkshire on the scale of four miles to the inch. It is printed in colours, and shows all roads, with an indication of their character, as well as rivers, towns, villages and railway stations.

The Paris Motor-Car Exhibition.

General View of the Salon.

GENERAL IMPRESSIONS.

To say that the seventh annual Salon d'Automobiles eclipses all its predecessors is to give but a faint idea of the excitement that is at present prevailing at the Grand Palais, in the Champs Elysées, Paris. No sooner were the doors open on Friday of last week than the rush began, and within a few minutes the building was a mass of people representative of all nations. The Show was officially opened by M. Loubet, who arrived about 10.30 a.m., and who, after spending some time at the leading stands, subsequently distributed the much-coveted red ribbon of the Legion of Honour to a number of persons prominent in the world of motoring, including M. Clément, M. Armand Peugeot, M. Henry Brazier, M. Brouhot and M. Krieger. As for the Exhibition, it can only be described as magnificent. Thousands of pounds have been expended on the stands alone, the elaborate drapery and festoons of flowers by day, and the myriads of electric lamps by night, making up a scene of amazing splendour. Some idea of the blaze of light after dark may be gathered from the fact that not only is all the available current from the central stations in the neighbourhood taken, but that several temporary plants have been put down, that entrusted to the Mors Company being of no less than 1,500-h.p.

The most vivid impression left on the mind after doing the round of the *Salon* is that of uniformity. The gradual evolution of a standard design of car seems to be almost approaching finality, there being few wide divergences from the normal types, and still fewer "freaks"; in fact, unless one includes such persistent survivals as the extensible pulley and the like, these latter are practically absent. It may be inferred from this that little in the way of novelty is to be expected; and there can hardly be said to be any distinctive feature by which the *Salon* of 1904 is marked, as was the case with previous shows. Not that advance and improvement are absent, by any means, but they are chiefly in matters of detail. Accessibility, facility of adjustment, neater methods of control, lubrication and carburation arrangements have all received obvious attention, improvements in one or more of these directions being visible on nearly every stand. There seems to be more inclination on the part of French builders to cater for "the man of moderate means," there being few stands on which a light car is not to be seen. Up to 8-h.p. the single-cylinder engine is the favourite, the twin-cylinder being used for cars of from 10 to 12-h.p. Even allowing for the natural fact of exhibitors preferring to stage their largest cars, however, the prevalence of four-cylinder engines is marked, as their proportion is 72 per cent., to 6 per cent. of two-cylinder and 9 per cent. of one-cylinder cars. The three-cylinder car has evidently progressed, and now outnumbers the two-cylinder, while the horizontal engine has apparently succumbed, at least as a native, its last French defenders, Gillet-Forest, showing a vertical engine. There seems a tendency towards casting each cylinder, together with its water-jacket, separately, the use of copper and brass jackets shrunk on to the cylinders having made little if any progress. As regards inlet valves, the mechanically-operated type is steadily gaining ground, notwithstanding that the suction valve is retained by one or two leading concerns, notably De Dion-Bouton and Panhard-Levassor, the latter on engines up to 15-h.p. Pressed steel frames are all but universal, and appear on the De Dion and Renault cars, while the 50-h.p. Panhard has an armoured wood frame in which there seems more "armour" than wood. High and low tension magnetos far outnumber accumulators, and appear about evenly divided, while the tendency to fit both ignitions seems diminishing, which may be somewhat regretted, as there are good grounds for holding that two ignitions, capable of being used simultaneously, are not without advantage. The over-elaboration of carburettors is not so evident as last year, but substantial progress in these is noticeable, the Renault and Brasier double-jet systems and the self-adjusting Decauville carburettor, in which the governor is made to regulate the air inlet, attracting attention, while both the Renault and Decauville cars have a variable mechanism to their mechanically-operated valves by way of throttle. Live axles are rather more numerous than chain drives, and in several instances springs have been introduced, the Roy device being a large spiral spring in tension, of about ¾ in. section, surrounding the propeller shaft, while in the other cases small

Digitized by Google

spirals in compression are used. Chains, where employed, are for the most part shorter, with gear-boxes placed further back and connected with the clutch by some more or less flexible coupling. Expanding brakes are largely replacing exterior ones, the chief novelty in these being the pneumatic brake on all four wheels, with rams about 2½ in. diameter, exhibited on the Mercédès stand. A good number of cars have the Truffault friction shock absorber on the springs, while the use of a few short spring leaves on the upper side of springs for the same purpose is also in evidence; springs for the most part are carried outside the line of *chassis*. Honeycomb radiators have by no means ousted tubular ones, being only one-third as numerous; but fans are usual, opinion being about equally divided between placing them in the fly-wheel or behind the radiator. The circulation in the majority of cases is by pump, but Renault, Richard-Brasier and one or two others still adhere to the thermo-syphon system. Metal clutches have increased in number, but not much, direct or inverted cones being most popular, while some combinations of both systems are shown. The new De Dion clutch is a noteworthy device, while an interesting new departure is to be seen in the clutch on the 50-h.p. Panhard car. In change-speed gears, the *train balladeur* or sliding pinion type still holds its own, most makers now, however, providing for a direct drive on the top speed. A striking feature is the great prominence given to the side-entrance covered vehicle for touring purposes—landaulets, coupés, and double phaetons. Indeed, in cars of this class it would seem that a side entrance is now *de rigueur*, few if any of the old limousines with rear entrance being visible. It is to be noted, however, that the bodies now being fitted are somewhat heavier than formerly, and although the *chassis* remains the same, the weight of the complete car is greater. The result is that more power is needed, and that cars intended for touring purposes are rarely fitted with engines of less than 15-h.p. The tonneau and front-entrance double-phaeton types of bodies are still very popular for open cars.

THE EXHIBITS.

The exhibit of the WOLSELEY TOOL AND MOTOR CAR CO., LTD., marks an epoch in the history of this well-known concern, inasmuch as a car with a vertical engine is shown for the first time. Only a *chassis* is to be seen, but it is representative of a new two-seated car which is being introduced. The single cylinder is 4½ in. bore by 4½ in. stroke; the normal speed being 800 revolutions per min. The water-jacket and upper half of the crank-case are in one casting. The explosion chamber, with its water-jacket and valve chest, is a separate casting bolted on to the lower part. The valves are mechanically operated off one cam shaft, the inlet valve being located in the cylinder head. The pump is driven off the cam shaft. The commutator is also actuated off the cam shaft through bevel pinions, so that it is brought into a most accessible position. The radiator is of the ribbed tube type set in a frame forming the water tank. The transmission is also a new departure for the Wolseley Company, being through an internal cone clutch, gear box, cardan shaft, and live axle. The change speed gear-box, which is supported directly on the pressed steel frame, is adapted to give three forward speeds and a reverse. The cardan shaft and the axle are completely enclosed in an aluminium casing. Long dumb irons are fitted to the rear springs, the latter being of good length and outside the frame. The foot brake acts upon a drum on the cardan shaft, and the hand brakes on drums connected with the hubs of the rear wheels. The clutch and brake pedals are of the push-forward variety, and the hand brake lever of the pull-up type. The brake pedal is connected with the throttle in such a way that when the brake is applied the speed of the engine is automatically reduced. One of the standard 6-h.p. Wolseley cars, with horizontal engine, is also displayed, and side by side with it is a *chassis* of the 8-h.p. car. This has a double-cylinder engine of a new type, there being no central bearing to the crank shaft. The connecting rods work on to one crank, so that there is an impulse every revolution, a heavy balance weight being provided on the shaft. The drive is by Renold silent chain to the gear-box, which is in one with the casing to the differential on the counter-shaft, whence the power is conveyed to the road wheels by side chains. Four forward speeds and a reverse are provided. Fig. 2 depicts the 12-h.p. double landaulet, which is being shown for the first time. It has been introduced to meet the demand for covered vehicles, and, while following the usual general arrangement of Wolseley cars as regards the engine and transmission, a number of changes have had to be made to accommodate the new form of body. Thus the engine—a two-cylinder horizontal one—is below the driver's seat, the sides of the latter accommodating the radiator, which is thus in two parts. A light shaft extends across the frame just under the seat; it is driven by a belt off the engine, and carries at each end a fan to induce a current of air through the radiator. The steering is of the Panhard type, while we notice that the usual dumb irons at the rear have been replaced by springs. The vehicle, which is luxuriously upholstered, can accommodate six persons, including the driver, and is altogether an excellent example of modern automobiles for town work. The Wolseley Company also exhibit a 60-h.p. four-cylinder vertical engine for a launch, and a range of connecting-rods and pistons extending from 4 in. to 12 in. in diameter, the latter being the size used in the engines employed in submarines.

Messrs. C. S. ROLLS AND Co. were apparently fortunate in the lottery for space wherein to exhibit, for the first time, the new "Rolls-Royce" cars. The vehicles, which have been designed in consultation with the Hon. C. S. Rolls, are manufactured by the well-known engineers, Messrs. Royce, Ltd., of Manchester. The vehicles on view include a 10-h.p. two-cylinder, a 15-h.p. three-cylinder, and a 20-h.p. four-cylinder car. A 30-h.p. six-cylinder vehicle is also being made. The cars have been designed on the multiple system, which gives complete interchangeability of parts. The cylinder dimensions (95 mm. bore by 127 mm. stroke) are

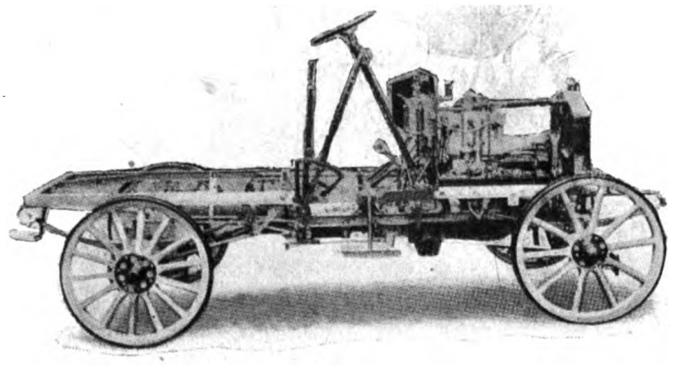

Fig. 3.—Chassis of the Rolls-Royce 10-h.p. Car.

the same for the two, four, and six-cylinder cars; such parts, therefore, as valves, pistons, connecting rods, etc., are the same in all types and are interchangeable. The valves are mechanically actuated, the inlets being located in the cylinder heads. The crank shaft is provided with bearings at the ends and on each side of every crank. The crank chamber is of aluminium, and is in halves jointed horizontally, the lower half carrying the bearings. An inspection door is provided to enable the connecting rods to be examined without dismantling. The cams on the half speed shaft are machined from a solid bar, and are driven by completely enclosed spur wheels. The ignition is by coil and accumulators; the commutator is fixed on the dashboard, and is provided with high and low tension portions, a single coil and trembler being used. To avoid the necessity of moving both the commutators and the various connecting wires or sliding contacts, the drive of the revolving portion of the commutator is arranged to be advanced or retarded by sliding one member of the skew gear along its shaft. The carburettor is of the float-feed spray type, and is fitted with a special automatic valve which accurately adjusts the carburation for all speeds of the engine, and enables the latter to run "dead slow" with the maximum of torque when required. It is provided with a throttle, to enable the gas to be shut off by the governor when descending hills, or when the speed becomes too fast. The governor, which acts on the throttle, is controlled from the steering wheel, by means of which it can be set to control the engine at almost any speed from 140 to 1,400 revolutions per minute, equalling respectively about 7 to 36 miles per hour on the top speed. A pedal is also provided by means of which the governor can be cut out and the speed of the engine consequently accelerated. The pump is of the cog wheel type, and is driven by skew gearing off the half-speed shaft. The radiator consists of vertical thin solid drawn brass tubes, through which the water circulates, with horizontal brass plates, which act as cooling surfaces. A fan is provided to draw a current of air through the radiator, this being mounted on a swinging bracket, so that the tension of the driving belt may be readily adjusted. The clutch is of the leather-faced internal cone type; it is connected to the gear box by a universal joint. Three forward speeds and a reverse, with a direct drive on the top speed, are provided, the power being conveyed to the rear live axle by a cardan shaft. The rear axle consists of a central aluminium case containing the bevel gears and the differential; attached to this case are two solid drawn steel tubes, upon each of which is mounted a road wheel. Inside the tubes is the revolving shafts driving the road wheels from the differential in the bevel gear case. The revolving shaft has fitted on squares on its outer ends jaw clutches, which engage with teeth formed in the outer ends of the road wheel hubs. The steering is by means of a steel worm working in phosphor bronze sector, provision being made to take up the end play in the worm by means of an adjustable bush. The frame is of the usual pressed steel pattern, being deepened in the centre to prevent deflection, and is long enough to provide a roomy side entrance body, the wheels being placed well back for this purpose. The front axle is of nickel steel, having each end formed into a deep and substantial fork supporting a vertical pivot on which the road-wheel rotates. A special oil-retaining and dirt-excluding hub is used for the road wheels, the end play being taken up by central flanges and washers, which are advantageously arranged to ensure good lubrication. The foot brake is at the rear end of the gear-case, and acts through the differential gear; the brake blocks are supported by vertical levers which are drawn together by a smaller lever on a floating fulcrum. The hand brakes are of the internal double-acting type having metal to metal surfaces, and are formed by expanding two curved levers within a drum, which forms part of the driving-wheel hub. Ample adjustment is provided for taking up the wear, and the brakes being double acting, the car is held equally well backwards or forwards. These two side brakes are compensated by a special arrangement of levers. The lubricator is placed on the dashboard; it consists of an aluminium vessel containing a pump driven from the engine by belt, the pump being used to force oil continually at a pressure of, approximately, 20 lbs. per square inch, and capable of being regulated to give the necessary feed to the various bearings about the *chassis*. A hand-pump is also provided by which the engine can at any time be given an extra supply of oil. The engine is so accurately balanced, and the carburation so perfect, that when the car is standing still there is an entire absence of noise and vibration; while when the car is running the only noise heard is the ticking of the trembler coil. The claims on this point, and also that the car can be almost entirely driven on the top direct speed, were borne out in the course of a short spin we made in one of the 10-h.p. two-cylinder cars with Mr. Rolls, who also gave us a demonstration of how the car could get away from a standing position on the top speed.

Four different models are being made by Messrs RENAULT FRERES for the 1905 season, viz., 8-h.p. single-cylinder, 10–14-h.p. double-cylinder, and 14–20-h.p. and 20–30-h.p. four-cylinder, specimens of each of which are on view. Fig. 5 depicts the motor of the 8-h.p. car, from which it will be seen that while the valves are mechanically operated the arrangement adopted is quite a new departure. The ignition is by high-tension magneto

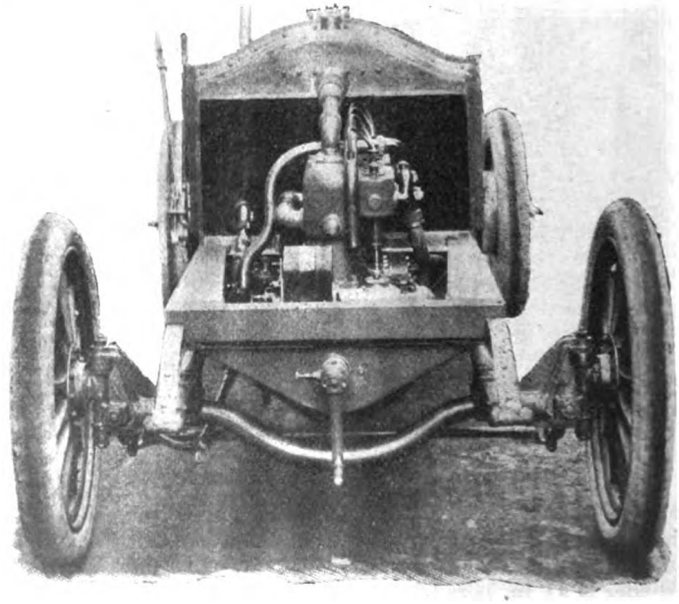

Fig. 4.—Front View of Renault 20-30-h.p. Car. (*See page* 865.)

Digitized by Google

mounted on the end of the cam shaft. The water circulation is on the thermo-siphon system. A view of the engine on the 10-14-h.p. car is given in Fig. 6, in which the arrangement of the mechanically-operated valves and the high-tension magneto is clearly shown. It will also be observed that the rim of the flywheel is provided with vanes to force a current of air through the radiator, which is set in a frame, comprising top and bottom water tanks, the whole being mounted on the front of the dashboard. By the action of the fan-shaped flywheel a very powerful suction is caused underneath the bonnet, and

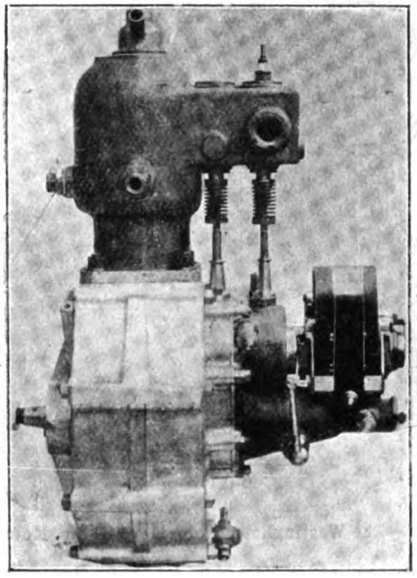

Fig. 5.—The Renault 8-h.p. Motor.

thus a strong current of cold air is forced through the radiators. The engines of the 14-20-h.p. and the 20-30-h.p. cars are similar to the 10-14-h.p., except that they comprise four cylinders. It may be mentioned, however, that the 8-h.p. and 20-30-h.p. engines are fitted with a compression release to facilitate starting. In all the motors a special wear-resisting metal is used for the bearings; the inlet valves, too, are provided with the variable lift device Messrs. Renault have used so successfully for several years. In the larger engines an automatic governor is provided, this acting on a butterfly valve on the admission pipe; a pedal

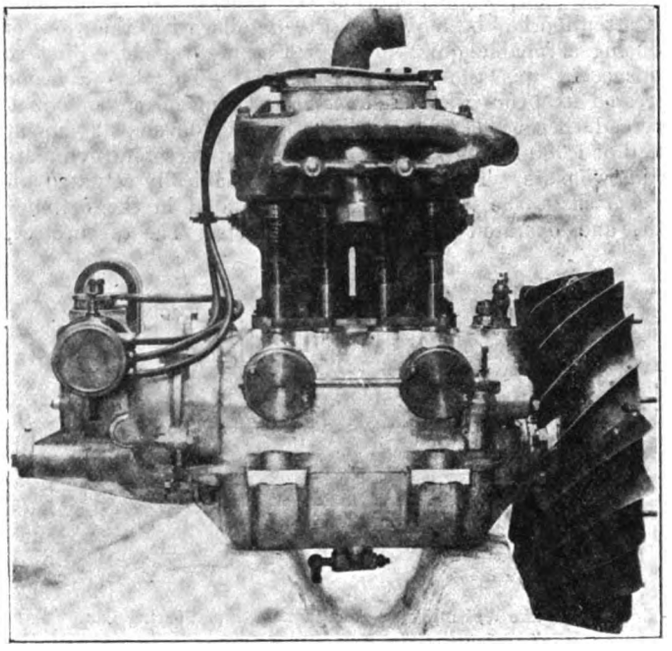

Fig. 6.—The Renault 10-14-h.p. Motor.

admission pipe and commands the auxiliary air inlet by a rod. The clutch is of the leather-faced cone type arranged to give a gradual engagement. The change speed gear has been slightly modified; it is adapted to give three speeds forward and a reverse with direct drive on top speed. The cardan shaft and live axle system of transmission is still retained, but we notice that a new form of spherical universal joint is being used. The brakes are of the metal-to-metal expanding type. A shield extending well to the rear protects the under side of the engine, clutch, and gear box from mud. A noticeable departure is the adoption of pressed steel frames and the suppression of the subsidiary frame for the support of the engine and gear box. The springs are of good length, and we notice that an additional transverse spring is now provided at the rear in the case of the larger cars.

The CUDELL MOTOR COMPAGNIE displays three types—

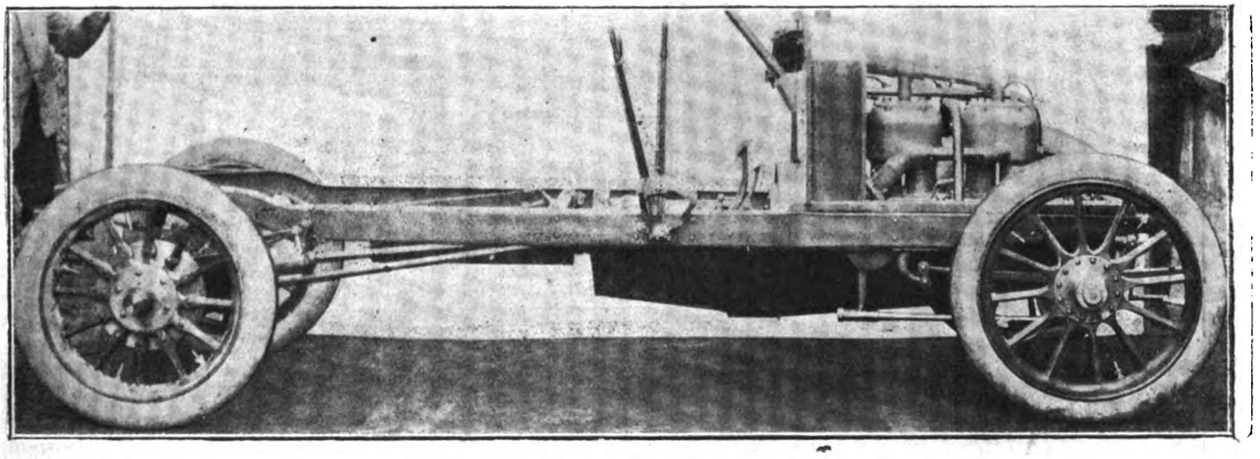

Fig. 7.—Chassis of Renault 20-30-h.p. Car.

accelerator is also fitted. The cam shafts have the cams cut therein out of the solid. The ignition is so arranged that it is automatically advanced or retarded, the hand lever usually fitted being now abandoned. A new form of automatic carburettor is also employed, enabling the air lever to be also dispensed with. The supplementary air admission is regulated by a brass disc, which partially closes the

10-h.p. double-cylinder and 20 and 35-h.p. four-cylinder. The largest *chassis* is a very interesting model, the engine having both the inlet and exhaust valves located in the cylinder heads, being mechanically actuated off one cam shaft by rods and tappets. The crank shaft, too, is mounted on ball bearings. The frame is of pressed steel, while the axles are of tubular steel made by Messrs. Krupp, of Essen.

A new-comer to the Salon is the Société Westinghouse, of Havre, which has recently taken up the construction of automobiles, and exhibits a number of cars built to the designs of M. Albert Schmid. It may be said at once that the Westinghouse-Schmid cars—this being the name by which they are to be known—are likely to take a prominent place among high-grade automobiles; for, while following the generally accepted lines, great attention has been paid to the details, with the view of producing a reliable quiet, and easy-running vehicle. First to be inspected was the 20-28-h.p. *chassis*. This has a frame of pressed steel construction, supported by long springs on equal-sized road wheels. The engine (Fig. 9), which develops 24-h.p. at a speed of 1,000 revolutions per minute, comprises four cylinders cast in two pairs The valves are all mechanically actuated off one cam shaft, the inlet valves being located in the cylinder heads, and operated by rods and tappets. The carburettor,

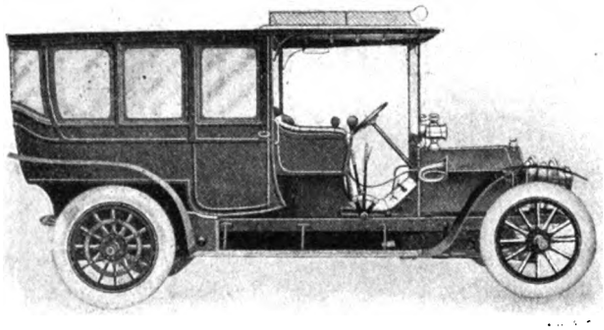

Fig. 8.—The Westinghouse-Schmid 20-28-h.p. Touring Car.

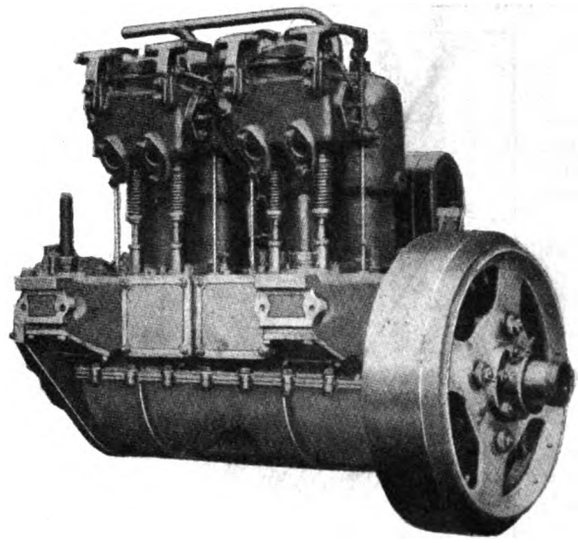

Fig. 9.—The Westinghouse-Schmid 20-28-h.p. Motor

magneto, and pump are all mounted on the engine. The magneto is of the high-tension type, and is gear driven. The governor is enclosed in the crank chamber; it acts on a piston throttle regulating the admission of gas to the engine; the carburettor is of the automatic air regulation type. The water circulation is maintained by a gear-driven pump and a honeycomb radiator. The clutch, which is of the leather-faced cone type, is so arranged that it can be removed without interfering with the engine or the gear box. The latter is adapted to give four speeds and a reverse with direct drive on top speed

cylinders cast in two pairs, the inlet valves being on one side and the exhaust on the other, all being mechanically actuated. It is in the transmission, however, that the principal novelty lies. The power is transmitted through a leather-faced clutch to a gear-box, from which extend two cardan shafts, one driving on to the rear axle and the other on to the front one, so that all four road wheels are driven. No less than three differential gears are employed, one on each of the axles and one in the gear-box. It is claimed that the car is proof against side-slip, and that steering is in no way affected. The gear-box is adapted to give

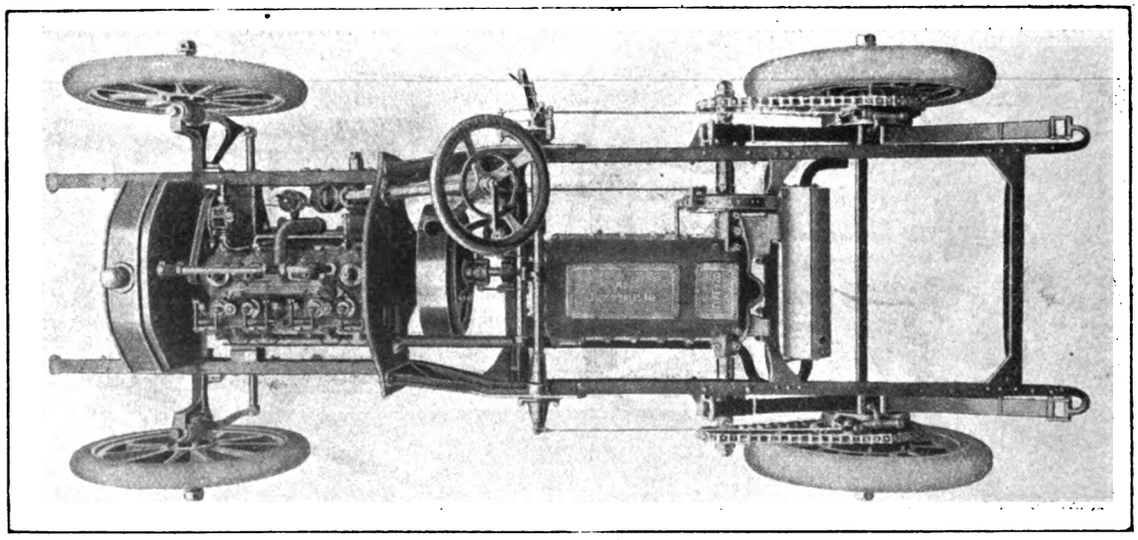

Fig. 10.—Plan of Chassis of Westinghouse-Schmid 20-28-h.p. Car.

The shafts in the gear box run on ball bearings. From the differential shaft the power is conveyed to the rear road wheels by side chains. We notice that the steering bar is placed behind the front axle instead of in front as usual. The vehicles exhibited include a side-entrance double-phaeton with canopy and a handsome side-entrance limousine (Fig. 8). The latter has an unusually long wheel base, the rear part of the body having

three speeds forward and a reverse. We noticed that the live axle does not carry the weight of the car, the road wheels being mounted on a sleeve, and having the power transmitted to them through the axle ends. As regards the standard Spyker cars, these are shown in two sizes, 16-h.p. and 20-h.p., both having four-cylinder engines. The car follows the usual lines of cardan-shaft transmission vehicles, among the features being the

Holland is represented by the SPYKER COMPANY, at whose stand we met Mr. A. House, of Bradford. The novelty of the display is the *chassis* of a 35-h.p. four-cylinder car. The frame is of pressed steel filled in with ash, while the engine has the

Digitized by Google

ready means of access to the pinions in the gear-box, and the pivots of the front wheels, which are entirely enclosed and work in an oil bath. Ball bearings are used throughout, while the brakes are of the metal-to-metal type.

Prominent among the few British firms exhibiting at the *Salon* is the HOZIER ENGINEERING COMPANY, LIMITED. This firm has given quite a national appearance to its stand by the adoption of a design composed of stately columns of imitation granite supporting a stone arch. This is set off with stags' heads, surmounting shields on which are placed crossed claymores. Over the stand are

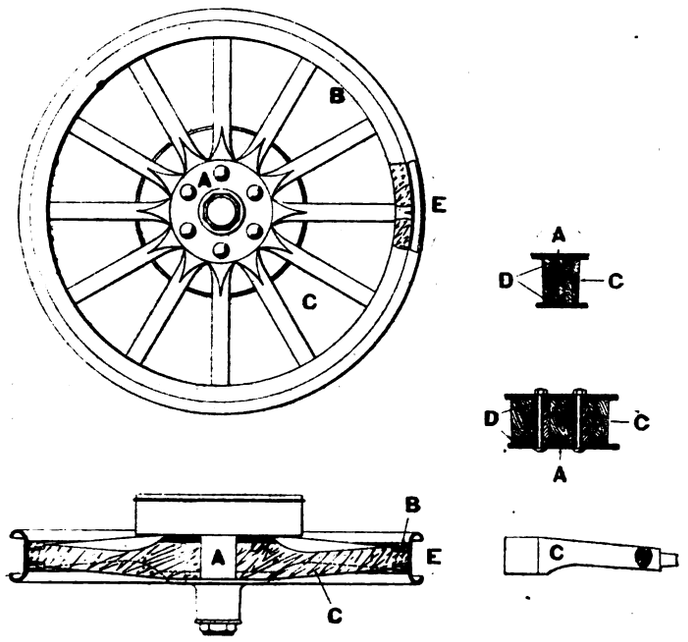

Fig. 11.—Details of "Staggered" Wheel of Argyll Car.

A—Iron Hub. B—Wheel Felloes. C—Spokes, right and left hand.
D—Fibre Packing between small edge of spokes and rim of wheel. E—Steel rim of wheel

draped the national flag of Scotland, the Union Jack and the Tricolour. The exhibit itself consists of two Argyll cars, a *chassis* and a number of special novel features. One of the cars is a 10-12-h.p., fitted with an Aster two-cylinder engine, built with a long frame, on which is mounted a handsome side-entrance body. The body is built of pressed sheet metal, and is on Roi des Belges lines, the tonneau being very roomy and comfortable. We learn that the engine has been completely re-designed by the Aster Co. in consultation with the Hozier Co., in order to better fit it to the requirements of this popular type of car. The most striking alteration is the arrangement of cylinders and valves. Separate castings are employed and the mechanically-operated inlet and exhaust valves are arranged on opposite sides. The water spaces around the cylinders are greatly increased, and the diameter of the valves is much larger than before. The commutator is no longer on the end of the cam shaft, but in a much more accessible position, being driven by a small shaft lying at about 45 degrees to the vertical. The thermo-syphon system of cooling is still a feature of this car, but the type of honeycomb radiator has been changed, the feature being the section of the tube used; this is hexagonal at the ends and like a cross in the middle, and, as a consequence, a large cooling surface is obtained and very free circulation for the water. In order to obviate any chance of leakage due to the springing of the joints as a result of road shocks, the radiator is carried in a cradle, and is supported on a bed of soft material, which deadens the shock and keeps the radiator from being strained. To facilitate the cooling of the water, a well-designed fan built up of six aluminium blades set on a brass centre and driven by a belt is placed behind the radiator. The fan is run on a spindle carried eccentrically, and so arranged that the belt can be tightened by simply turning the spindle round and clamping it. The well-known Govan change-speed gear is still fitted; certain minor improvements may, however, be noticed. A ball bearing has been introduced into the gear-box to lessen the friction when running free wheel to the low gears. The common form of pin joint for the control levers leading to the carburettor, commutator, &c., has been substituted by a neat form of ball-and-socket joint. The steering is effected by a triple-threaded screw turning in a phosphor-bronze nut, the whole being encased and working in thick oil or grease. The front axle has been re-designed, the swivels now being carried between the jaws of a cast-steel fork at either end of the curved and brazed tube which forms the axle. A ball bearing is introduced in the swivels to allow of easy steering. The rear axle runs on roller bearings, and consists of nickel steel shafts, with mild steel cut gears, case hardened. These are supported by a suitable case and outer tubes carefully stayed to prevent sagging. The road wheels are built on a new and patent principle (Fig. 11), the point aimed at being great lateral strength, so as to be capable of resisting the strain caused by side-slip, etc. To achieve this the spokes are "staggered" in the vertical plane, alternate spokes passing to the right and left sides of the iron hub. The joints between the spokes are so arranged that should the wheel at any time become loose through the wood shrinking, it can be tightened up by drawing together the hub flanges by means of the bolts holding the hub together. The front road wheels are carried on ball-bearings. The three-cylinder 12-14-h.p. car is fitted with an "Argyll" engine, the cylinder dimensions being 90 mm. by 120 mm. stroke. The car itself is a detachable tonneau, built on Roi des Belges lines. The wheel base is 7 ft. and the track 4 ft. 1¼ in. The engine is of compact design; it is provided with a centrifugal governor acting on a definitely-balanced double-beat throttle valve. The commutator is situated below the bonnet and readily accessible; the pump is a centrifugal one, gear-driven at the same speed as the crank shaft, and is so placed as to be easily detached if required. The engine is hung direct from the pressed steel frame by brackets cast on the crank casing. Probably the most popular improvement made in these cars is the clutch: the metal and leather type has been abandoned in the case of the three and four-cylinder cars, and the Hele-Shaw metal to metal clutch adopted (Fig. 12). This clutch is encased in

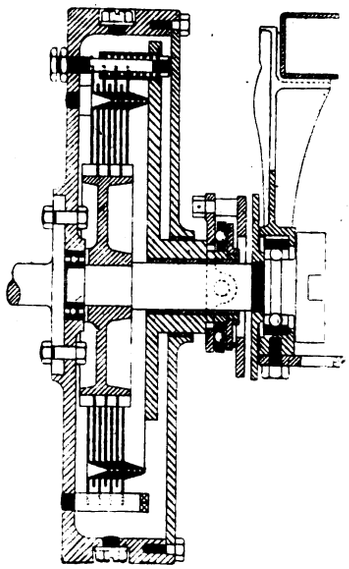

Fig. 12.—The Hele-Shaw Clutch on Argyll Car.

the flywheel and runs in an oil bath, and consists of a series of discs of steel. The alternate discs are notched along the outer and inner circumferences. The one set of discs engage with all projections within the fly-wheel, while the alternate set mesh with ribs or keys on a boss on the gear-shaft. The plates are kept in contact by a coiled spring. The action of the push pedal in disengaging the clutch is to overcome the pressure of this spring, and allow a set of small springs between the steel discs to free the plates from each other. The advantages claimed

Digitized by Google

for this device are:—(1) great gripping power, (2) large wearing surfaces, kept well lubricated, (3) the motion is imparted to the car without shock, and (4) the clutch can be allowed to slip any amount that may be wished. This feature is a very valuable one, as it allows of the car being driven slowly on the top gear with the engine running at its normal. We learn that for the 1905 season the Hozier Company will manufacture a four-cylinder touring car of 20-24-h.p., fitted with an "Argyll" engine having cylinders 95 mm. bore and 130 mm. stroke. The wheel base is 9 ft. 3 in. by 4 ft. 6 in. track, which allows of a very roomy side entrance body being fitted. A splendidly finished *chassis* is shown on the stand. All the best points in the design of their other cars have been incorporated, as well as some features peculiar to this type. In examining the *chassis*, one is specially struck by the quality of the workmanship, and we note with pleasure the marked advance which this firm has made in this respect even on last year's exhibit. The pressed steel frame is of an inverted U section, deep in the middle and tapering towards the ends. On this *chassis* is shown a new joint for the cardan shaft. This consists of two steel sleeves, one keyed to the driving and the other to the driven shaft; each sleeve ends in a double prong, the edges of which take the form of epicycloidal teeth, the teeth being parallel to —instead of as in a gear wheel at right angles to—the axis

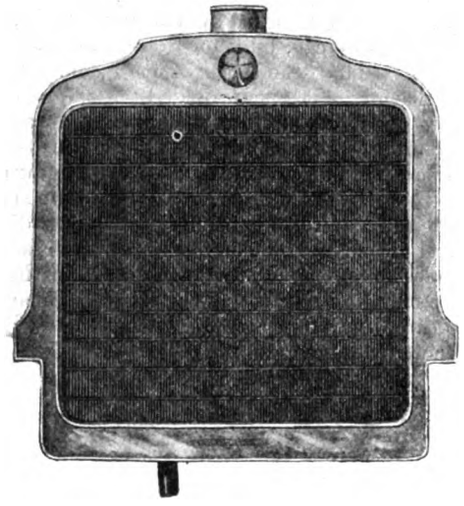

Fig. 13.—The Grouvelle-Arquembourg Framed Radiator as used on Richard-Brasier Cars.

of the shaft. These teeth when meshed together form a hollow sphere. Inside this is placed a ball to keep the teeth in proper relative positions, the whole being covered by a dust cap. The advantages claimed are, sweet running and large wearing surfaces, the teeth rolling on each other when the cardan shaft revolves. The back axle has the same general appearance as that fitted to the 1904 "Argyll," but it is so arranged as to permit of its being opened out without removing it from the car. This is obtained by dividing the case containing the bevel gear and differential on a horizontal plane through the centre. Besides this a large inspection door is provided to allow of the condition of the gear being readily ascertained at any time. The live axle is of nickel steel of ample proportions, while the machine-cut steel gears are of good size and excellent workmanship; in fact, the whole *chassis* is a creditable piece of work.

Messrs. GROUVELLE AND ARQUEMBOURG, whose radiators are employed by most of the leading French concerns, have a big display of their *refroidisseurs cloisonnés*, or framed radiators for use in connection with the water circulation of petrol motors. These radiators are made in several forms, each in a variety of shapes and sizes. Thus there is the plain radiator, set in a neat frame; a similar cooler, but fitted with a fan to induce a current of air through the air spaces formed by the radiating ribs; and finally the framed radiator with water tank and fan combined. The latter are made in a variety of shapes to meet the desires of different manufacturers. A new carburettor adapted for cars and motor-cycles is also displayed. Two views of the smaller type are given in Fig. 14; it is of the constant-level pulverising type, and consists of a chamber A, in which is a float fitted with a needle valve which closes the petrol inlet as the float rises. From the chamber the spirit passes to the spraying chamber F, placed transversely at the rear. The latter is of special design, the internal surface being in the form of a sinuosoidal curve, by means of which the suction of the motor, even when the latter is running slowly, is claimed to be sufficient

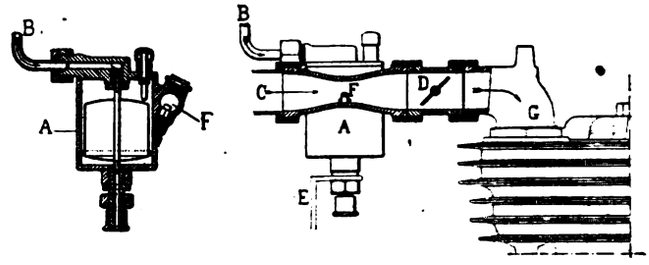

Fig. 14.—Sectional Views of Grouvelle Arquembourg Motor-Cycle Carburettor.

to maintain a constant carburation. The carburettor, which is so arranged that it can be readily taken to pieces for cleaning purposes, is provided with a throttle valve D. As will be seen, the device is exceedingly simple and compact.

The pressed steel frame, with mud-protecting shield forming part of the same, still forms a prominent feature of the cars made by LA SOCIETE NOUVELLE DES ETABLISSEMENTS DECAUVILLE. For the 1905 season six models are being made, viz., 12-h.p. double-cylinder, and 12-16-h.p., 16-20-h.p., 24-28-h.p., 30-35-h.p., and 40-50-h.p., all four-cylinder. The two last named have side-chain transmission, while the others have the standard Decauville live axle, in which the rear road wheels are not fitted

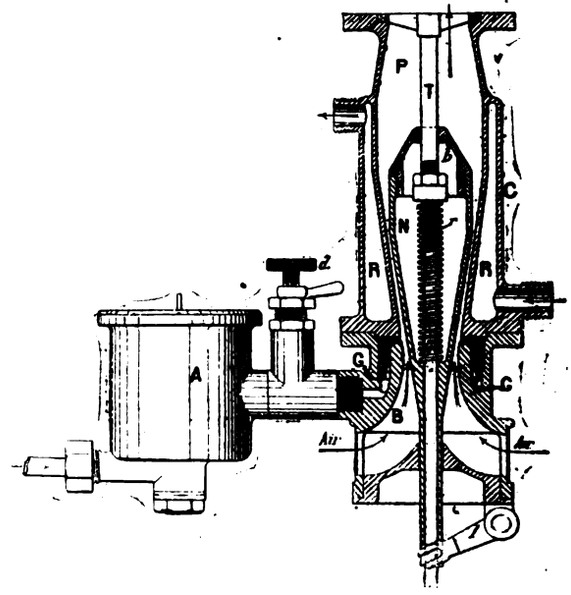

Fig. 15.—Section of Decauville Carburettor.

on the axle but on a sleeve surrounding the same, the power being transmitted to them through "dogs" on the ends of the axle. A new form of automatic carburettor is one of the Decauville Co.'s most striking apparatus for the 1905 season. In the new device all the air has to pass round the spraying nozzle, and this, with the variable opening for the admission of air, gives an automatically-controlled perfect mixture at all engine speeds. A sectional view of the new carburettor is given herewith, from which it will be seen that it comprises the usual float-feed chamber and a conical mixing chamber C. Within the latter is

Digitized by Google

a moveable cone N, by means of which the quantity of air admitted through the two openings at the bottom is automatically regulated, the cone N being more or less raised by the suction of the motor against the action of the spring. The spirit is drawn in through openings in the cone G. A hot water jacket, R, is provided to the mixing chamber C. Provision is also made in the four larger cars whereby the quantity of gas admitted to the cylinders may be varied from that drawn in during the complete suction stroke down to zero. This is effected in an ingenious yet simple way and without in any way affecting the valves or their lift. A clutch pedal is connected up to the new arrangement, so that as the clutch is withdrawn the supply of gas is automatically partially cut off.

The DARRACQ COMPANY has a magnificent stand, the design of which is intended as a reproduction in miniature of an Arabian

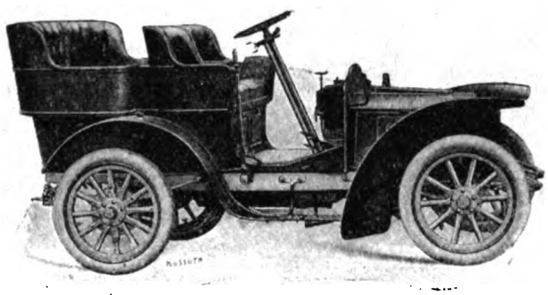

Fig. 16.—The Darracq 8-h.p. Car.

gateway. This is one of the few concerns whose 1904 models have been shown in England ere being exhibited in France, and as a description of the same was given in a recent issue of the *Journal*, no lengthy mention is necessary at the present time. It will suffice, therefore, to briefly state that for next year this concern is making seven types of cars: 8-h.p single cylinder; 12-h.p. double-cylinder; and 15-h.p., 18-20-h.p., 20-22-h.p., 28-h.p., and 30-h p. four-cylinder. The chief object of interest is the new model 8-h.p. car. The one on view is fitted as a four-seated car, with tonneau body, but it is also supplied as a two-seater. The vehicle has a pressed steel frame, in the forward part of which is set an 8-h.p. single-cylinder engine, 112 mm. bore by 120 mm. stroke. The inlet valve is mechanically operated, and is provided with a device in conjunction with the governor whereby its lift,

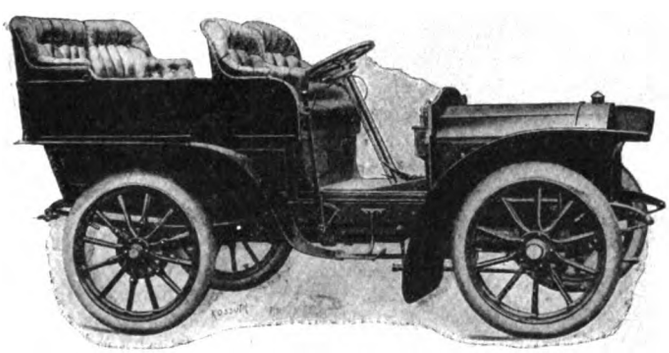

Fig. 17.—The Darracq 18-20-h.p. Car.

and consequently the speed of the engine, can be regulated. The change speed gear-box is adapted to give three forward speeds and a reverse controlled by, as usual in Darracq practice, a lever on the steering column. On the top speed the drive is direct through the cardan shaft and bevel gear to the live axle. The brakes are of the metal-to-metal expanding type. There are a number of detailed improvements in the car, among which may be mentioned the fitting of side panels to the front mudguards, which prevent the splashing of mud on to the front wheels. The exhibit also includes a 30-h.p. four-cylinder *chassis*, and examples of the 12-h.p. and 15-h.p. cars, among the latter being a handsome landaulet. The vehicles are on similar lines to the 1904 models, but comprise a number of changes in detail. Among these are the adoption of forged steel axles of H section; the steering column is now sloped considerably more, and magneto ignition can be fitted at the option of the purchaser, either alone or as a secondary ignition. The brakes are of the latest design, being internal expanding, metal-to-metal, and holding equally backwards and forwards. A new type of governor has been adopted, working on an eccentric controlled by hand and foot, and an improved form of pump is being used which makes it impossible for the water to leak, and at the same time is much more efficient than previous patterns. The Darracq Company is devoting much attention to side-entrance cars, all the larger vehicles being available in two lengths of *chassis*.

THE PANHARD-LEVASSOR COMPANY has lost none of its favour, if the crowds which continually gather round its handsome stand may be taken as any criterion. The smaller types of Panhard cars show but little change from last year. The armoured wood frame is still retained, as are also automatic inlet-valves on engines up to 15-h.p. In each case the cylinders are cast separate, and we notice that the 24 and 35-h.p. engines, which have mechanically-operated inlet valves, are fitted with an arrangement whereby the lift of the latter can be varied, enabling the engine to be started more readily, and its speed regulated. The "Eisemann" high-tension magneto ignition is still used, but an auxiliary battery is now provided, controlled by a two-way switch to facilitate the starting of the engine. Interest at this stand is mainly centred on the new 50-h.p. Panhard car. The four cylinders are cast separately, with the

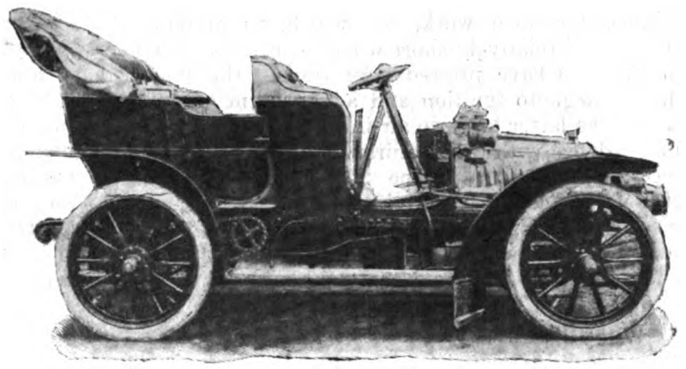

Fig. 18.—The Panhard Side-Entrance Double Phaeton.

mechanically-operated inlet-valves on one side and the exhaust valves on the other, while the five bearings which support the crankshaft have their caps bolted to the upper portion of the crank-chamber, to enable the lower half of the latter to be removed without disturbing the shaft. A new departure is found in the method of automatically governing the speed of the engine; the usual centrifugal governor is replaced by a hydraulic arrangement working in conjunction with the water-circulating system, the increased pressure of water—due to increased engine speed—being utilised to control the throttle-valve in the required way, the throttle opening being more or less closed according to the water pressure. Passing to the transmission mechanism, we find a new clutch consisting of a series of discs running in an oil box. The change-speed gear is of the sliding type, giving four speeds forward and a reverse, with a direct-through drive to the countershaft on the top speed When the latter is in use, the side shaft inside the gear-box remains stationary, so that the transmission losses due to friction are reduced to a minimum. It is worthy of note that all the cars on view are fitted with side entrance bodies.

The GLADIATOR COMPANY has four models on view—10-h.p. double-cylinder, and 11-h.p., 15-h.p., and 24-h.p. four-cylinder. The radiator is of the ribbed pipe variety set in a neat frame. The transmission is by side chains, and among the several noteworthy features may be mentioned that the cylinders are all cast separately, the inlet and exhaust valves being arranged on opposite sides and mechanically actuated. The differential gear is entirely separate from the change speed gear-box, the con-

Digitized by Google

nection between the two being by a jointed shaft. The wood and steel frame is still retained, but we noticed that the usual dumb irons at the rear have been substituted by halves of semi-elliptic springs. The larger cars are provided with both high-tension magneto and coil and accumulator ignition.

La Societe Mors has a large stand on which are shown five different sizes of cars, viz., 12-16-h.p., 14-19-h.p., 19-24-h.p., 24-32-h.p., and 40-52-h.p., these all having four-cylinder engines and frames sufficiently long to take side-entrance bodies, the

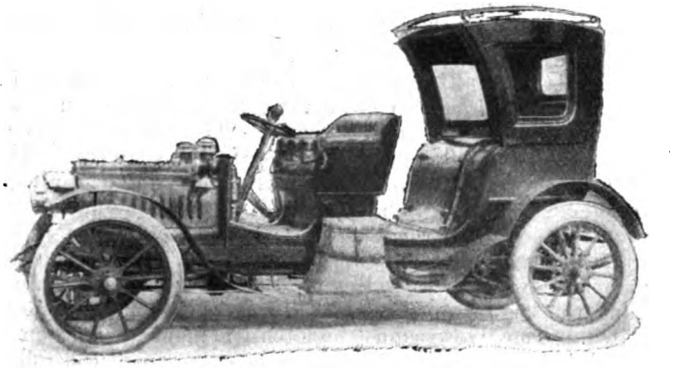

Fig. 19.—The Mors "Cab."

vehicles on view including a limousine coupé and a landaulet. The latter has the engine under the front seat, and has been designed for town work, for which, on account of its silent running and relatively short wheel base, it is excellently suited. All the cars have pressed steel frames, the motors have low-tension magneto ignition and a new form of automatic carburettor; the latter has two air inlets, the mixture being regulated in accordance with the requirements of the engine at different speeds. The engines of the 24-32-h.p. and 40-52-h.p. cars are fitted with a compression release device to permit the motor to be easily started, and a cog-wheel water circulating pump. The radiator is of the ribbed-pipe variety. A double cardan joint is provided between the clutch and the gear-box. The shafts of the gear-box in the 14-19-h.p., 24-32-h.p., and 40-52-h.p. cars run on ball bearings. The 40-52-h.p. car, which is designed for fast work, has a special steering gear and three rear springs, one lateral and two longitudinal. A feature of the motor is that the crank shaft is placed not in the centre of the cylinders, but a little on one side, as in the Mors racing cars of 1904, the object of this being to avoid the lateral reaction of the pistons.

A number of interesting light cars are are shown by M. Bailleau, of Longjumeau Fig. 20 shows the two-seated car; it has a tubular frame, and can be fitted with either a 6-h.p. or 9-h.p. single-cylinder De Dion engine with water circulation on the thermo-syphon system The change-speed gear is dapted to give three speeds forward and a reverse and a direct drive on the top speed. From the gear-box the power is conveyed by a cardan shaft to a live axle. The road wheels, differential, and clutch run on ball bearings. Altogether the Bailleau cars should meet the views of many motorists seeking reliable vehicles at moderate prices

La Compagnie des Automobiles Hurtu, which is now represented in England by Messrs. E. and H. Hora, Limited, displays two interesting models—10-h.p. double-cylinder and

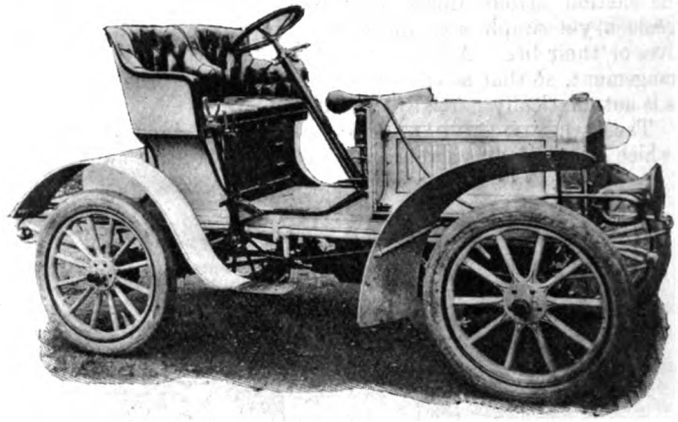

Fig. 20.—The Bailleau Light Car.

16-18-h.p. four-cylinder. The vehicles have pressed steel frames, narrowed at the front to increase the lock of the steering wheels. The engines have separate cylinders 85 mm. bore by 120 mm. stroke; the valves are mechanically actuated off one cam shaft, the inlets being arranged in the cylinder heads. The ignition is by coil and accumulator or by magneto as desired, the 16-18-h.p. *chassis* on view being provided with the latter. Four speeds forward and a reverse, with direct drive on top speed, are provided on the larger car, the 10-h.p. vehicle having, however, only three forward speeds. The gear box, which is supported directly on the main frame, is provided with ball bearings. The transmission is by enclosed cardan shaft to the live rear axle. All the brakes are of the metal-to-metal expanding type. To prevent strain on the engine or gear, a universal joint is provided on the clutch shaft. The cars appear to be built on sound lines, and, like all modern vehicles, can be fitted with side-entrance bodies.

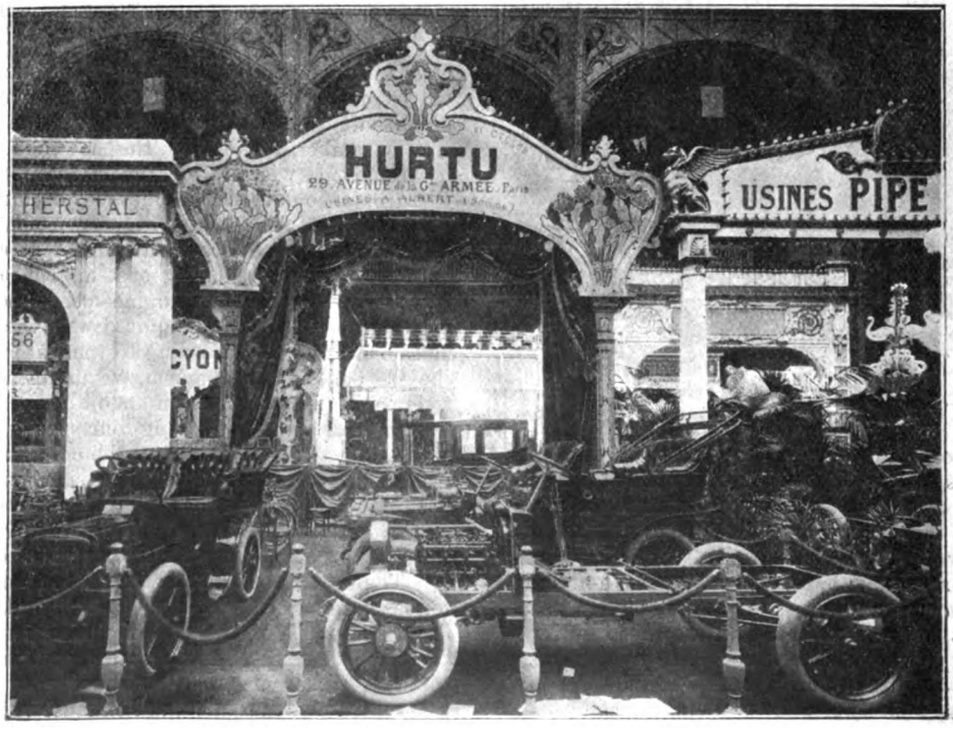

Fig. 21.—View of the Hurtu Company's Stand

Messrs. Desponts and Godefroy have a large display of radiators, both of the honeycomb and ribbed-pipe types, these being shown in a variety of shapes. "Jupiter" acetylene head-lights and mechanical lubricators are also to be seen, while of especial interest at the present time is their *chauffer-ette*, or foot-warmer for motor-cars. A description of this apparatus was given in a recent issue of the *Journal*, but it may be mentioned that it consists of an arrangement fitted in connection with the piping connected with the circulation of the engine cooling-water.

THE COMMERCIAL VEHICLE EXHIBITS.

By E. Shrapnell Smith.

I JOURNEYED post haste to the Serres de la Ville, in the Cours la Reine, on the morning of the 8th instant, rueing the fact that spells of intermittent driving over stretches of "Kleinpflaster" roads in Rheinland had occasioned so serious a delay as three days beyond the opening of this section of the *Salon*. My perturbationproved to be a quality of supererogation, for everything was chaos and ample time remained to me. The customary practice of certain exhibitors to be late had been distinctly widened by the unroofing of a portion of the

Fig. 22.—The Brillie Four-ton Petrol Lorry.

large glasshouse during the storm of the previous week. Machine tools, motor boats, petrol omnibuses, and steam lorries, were chiefly outside the building rather than in position on the stands. Horses strained in traces to *camions* upon which shapely hulls submitted, unresisting, to Philistine hands and methods in their unloading and staging; meanwhile the Seine glistened below, silently demanding the boats for her care and carriage. The approaches were ankle-deep in yellow mud, and sympathy forced one to take a turn at the wheels behind an exhausted hay-motor. A commissionaire before the entrance gate, where no turnstiles were yet, politely explained that my invitation card for the opening function, which was dated for the 9th, was not available on the 8th—in short, that to-day was not to-morrow. But a diplomatic reference to *The Motor-Car Journal* proved an irresistible *open sesame*.

Visits on succeeding days made it clearly evident that France is awakening to the scope which commercial vehicles offer. All the great houses are prepared to supply workmanlike small delivery vans and open trucks, to which end the *chassis* have been specially strengthened. It is no longer a question merely of superimposing a different body on the underframe of the pleasure car, for the models are essentially suited to the steadier and severer grind of daily service in business work. This development in the use of the lighter commercial types is reflected in the streets of Paris, one being complementary to the other, for it is a noticeable feature that, amongst the stream of automobiles which cheer the eye and gladden the heart of the motorist in the gay city, the occurrence of the *camion de livraison* daily becomes of greater frequency. Beyond this stage, heavy motor traffic has yet to advance. The motor-wagon, laden with its five tons of beer, of stone, of paper, or almost any load one may choose to name, which is regularly seen in any London line of traffic, is conspicuous by its absence here. Enquiry at the stands, and from members of the Automobile Club de France, particularly from my friend, M. Georges Forestier, the engineer-in-chief of the Department of Roads and Bridges, demonstrates, to the exclusion of contradiction, that France will never know the applications of the five-ton motor lorry as we do in England. The physical and commercial conditions of the two countries provide one explanation, for England stands alone in her volume of internal trade, taken in conjunction with the short distances between her productive centres and the high ratio of road mileage to superficial area, whilst, as regards town uses, it is only for regular loads of definite character that commercial success can result. London, and other English cities, apparently offer more opportunities of this kind. At least, the fact remains that there are probably ten times more five-ton lorries at work in London, where the roll exceeds a total of two hundred, than there are in Paris.

I went carefully over all that was exposed, twice and yet again. Not a few of the exhibits—it were kinder not to make particular reference—are doomed to a short existence when they reach actual use. The boldness with which some of the machines had been labelled for a *charge utile de* 4,000 *kilos.*, when perhaps 1,500 kilos. was a reasonable average load, tempted one to smile until the desire was checked by the certainty of bitter disappointment in store both for the user and the builder. It is the old story of ignorance of road conditions, for, no matter how brilliant the engineer, or how good the material, theory is rudely upset when it comes to running on bad roads, especially with iron tyres. The most promising vehicles, to my mind, were those exhibited by the Société des Automobiles Eugène Brillié (19, Rue Auber, Paris), whose construction is undertaken and carried out by MM. Schneider and Cie., Le Creusot and Havre; the *avant-train* of A. Latil, 9, Rue Neuve-de-Villiers, Levallois-Perret; the *trains automobiles à propulsion continue, système Ch. Renard*, shown by Surcouf and Cie., Rue de Bellevue, Billancourt; the Bretin lorry staged by Mathian Frères, 147, Rue de Tolbiac, Paris; and the five-ton steam lorry of Turgan, Foy and Cie., Rue Carnot, Levallois-Perret.

The construction of the Brillié vehicles is exceptionally solid and well thought out for the purposes in view. The four-ton type (Fig. 22) is fitted with an 18-24-h.p. four-cylinder motor, with both petrol and alcohol carburettors, and with high tension ignition. Magneto is added, to work on the same plugs if required. The motor runs, normally, at 900 revolutions per minute. The transmission is of the ordinary cardan type, with direct drive on the third forward gear, which is the highest; the transverse differential shaft is close to

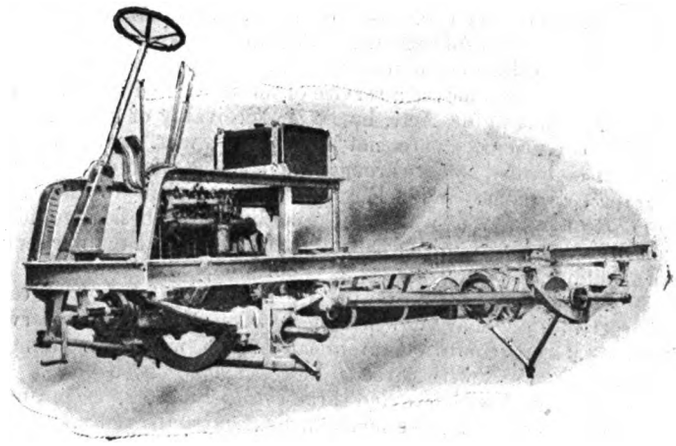

Fig. 22.—Chassis of Brillie Petrol Lorry.

the back axle, and carries pinions with twelve or fifteen teeth, which can be changed by a patented method of altering the centres of this shaft relatively to the internally toothed rings on the driving wheels. All is satisfactorily enclosed and oil-tight, whilst powerful Lemoine brakes are applied externally on the drums. The three speeds range from 2¼ to 7½ miles an hour, above which the engine can be accelerated by 30 per cent. The lorry, including platform, weighs 3½ tons, and I was able to examine the records of tests made on a gradient of 1 in 10, with a load of five tons, up which the climb was performed at two miles an hour on a wet macadam road, and this with only six-inch tyres on the driving wheels of thirty-seven inches diameter. The makers guarantee the b.h.p., and the speeds under load, and I observed that they

Digitized by Google

mploy a friction clutch having a metal face on the male member with the leather on the female face, which forms part of the engine fly-wheel.

The *avant-train Latil* is a neat, compact and promising invention, which has stood the test of time. It has been in use some four years, and the *Maison Goulet-Turpin*, of Reims, who bought one of the early machines several years ago, have bought three more, the last of these being on the stand. The two-cylinder engine and gear-box are carried transversely above the front axle, from the frame. Cardan shafts carry the drive to short shafts which run in bearings held in brackets which are part of the substantial flap castings of the front springs. On the outer end of each of these short shafts is a spherical jaw, smooth on the inside except for a horizontal projection, or fork, about three-eighths of an inch deep, which fits a groove cut in the steel ball, about two inches in diameter, which lies between the spherical jaw on the driving shaft and a similar spherical jaw, but with a vertical projecting fork, which is attached to the pinion which engages the internally toothed ring attached to each front wheel. This special ball joint gives the necessary play and an efficient drive, and the wear is practically *nil*. All the shafts are parallel, the motor is close to its work, and a remarkably high percentage of the engine power must reach the rim of the front wheels. The tare weight of the vehicle is under two tons for a load of 3½ tons, and the price is only £340, in Paris, including solid rubber tyres on the front wheels, with a 12-h.p. motor. I look upon this system as the novelty of the heavy section and hope to see it in London hereafter.

The Renard train has already been fully described in the *Journal*, so I shall refer only to the improvement that has recently been made in the suspension for the six-wheel type. The frame is carried on compensating rods which give points of support capable of accommodating themselves to the variable lifting of any wheel without any appreciable effect upon the level of the vehicle body as a whole. The arrangement also permits of the front or rear wheels being raised by irregularities on the road surface without any reduction in the load upon the centre axle, which requires the greatest possible weight for adhesion in driving. A number of the Renard vehicles have recently been ordered for service as omnibuses between Dieppe—Oriel—Le Treport. In England this system will have no practical application for road trains, as the use of more than one trailing vehicle removes a service of motor-cars within the pale of the Traction Engine Acts, but it is conceivably of great interest under conditions, as are not infrequently met, where a trailer cannot be hauled solely through the tractive effort of the towing motor car alone, and where the transmission to the trailer of part of the power, whereby the additional adhesion could be used for aiding propulsion as whole, might assure a regular service of a suitable character.

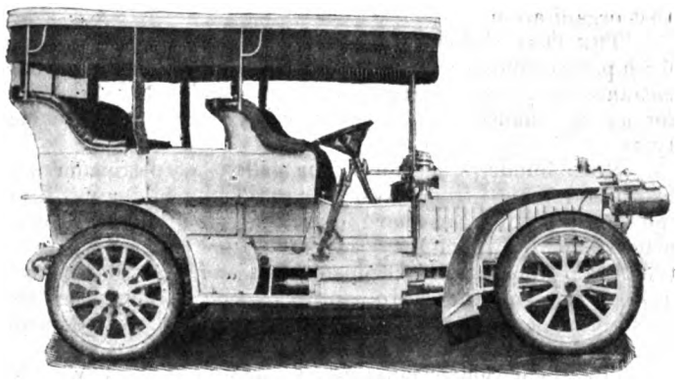
Messrs. Mathan Frères deserve mention principally because the petrol lorry they show has been taken from actual service, and because its condition, after nearly 7,000 miles of running in and around Paris with three to four ton loads, is so good. The vehicle is fitted with two and three cylinder motors, according to demand. This firm, like many in England and France, will hire their motor-lorries to any firm for two or more weeks, as a trial, for an inclusive charge, which in their case is from twenty-five to thirty francs a day. There is no special feature in the design that calls for reference.

The name of Turgan, Foy and Cie. is known to English readers and to all who have attended the *Poids lourds* trials at Versailles and elsewhere. It is a sign of the times that these builders of boilers and steam engines are also getting out internal combustion motors, though they have every confidence in the continued demand for *camions à vapeur* for years to come. Their 60-h.p. five-ton steam lorry and tractor is, indeed, an achievement of which they may well be proud, though the price of £960 seems rather stiff. The provisioning is ample throughout, no less than 245 gallons of water being carried, and this quantity is none too much for the normal load of ten tons, five each on the motor lorry and the trailer, when traversing heavy roads. A strong ratchet is fitted on the back axle to guard against any risk of running back, which is a useful provision where such great weights are in use.

My interest is, I must admit, ever in the heavier loads, for that is what will aid the British manufacturer and the agriculturist, so long as we can secure a true proportion between traffic, carrying agency and road structure. I do not overlook, however, the many encouraging signs that talent and capital are surely combining to elucidate the problem of mechanical road transport.

I have ventured to advise constructors to always avail themselves of every scrap of road experience before launching out into selling, and I now repeat that new-comers to the heavy branch of automobilism will find no royal road to success. It was interesting to learn from such constructors as the Société Decauville, the Société Delahaye, and the Société Peugeot, whose reputation as car builders is generally acknowledged, that they have been perfecting commercial lorries at their works for a long time past, and that they are now ready to supply to the public what they have proved to their own satisfaction in their own haulage over protracted periods. I hope they will rapidly develop their capacity, which remark applies to many other makers, such as the Hagen lorry, with 12-h.p. motor, a tare of 3 tons and the same useful load; the Krieger petrol-electric lorry, with 16-h.p. motor, a tare of 2½ tons and a useful load of 5 tons; the Bardon lorries, with 6 and 8-h.p. motors, having single cylinders but two pistons, for loads of 1½ and 2 tons respectively; the Zappa and Schars steam wagon, which is the first of its type, intended to take a 5-ton load; the De Dion-Bouton lorry, for about 2 tons of useful load, in which the front spring shackles hang on bifurcated leaf springs, which are bolted to the frame of the vehicle, whereby specially easy suspension is attained; the Delahaye light tower-wagon, which has been sold to the Alexandria and Ramleh Electric Railway; the four-cylinder 25-30-h.p. wagon by Adolph Saurer, Arbon, designed to carry 5 tons; and, last but not of least interest, the 2-ton lorry of the Neue Automobil Gesellschaft, whose London house, the N.A.G. Automobile Company, Limited, of G.B. and Ireland, of Great Portland Street, W., will be exhibiting at the Agricultural Hall, Islington, in March of next year.

It is a pity that the heavy vehicle section has been relegated to a building several hundred yards from the Grand Palais, though the fact that the motor-boats are similarly "outlawed" makes for the likelihood of a fair proportion of visitors. One is able to detect much in common with English practice, both in point of constructive details and business methods, and all the makers appear to look upon the commercial types as a growing asset to the industry. In conversation, I gathered distinctly that they recognise the necessity for reasonable prices and the fact that trade concerns will not, were they able, pay anything in the nature of fancy prices. Taking a line through the various quotations, French makers are selling 2-cylinder 1½-ton lorries which are capable of taking that load at an average of six or seven miles an hour at £350, inclusive of rubber tyres. This is below home prices, but the French machines are not so strongly built in the wheels, axles, or frames as English roads have proved to require, and the loads would have to be reduced accordingly. The diameters of the driving wheels seldom exceed thirty-four inches, and this is insufficient for smooth running except on good surfaces, whilst the platform areas are almost universally too small for the bulk of a load of general goods, such as groceries, provisions, fruit, or cotton. Some of the machines have very narrow platforms placed inside the wheel gauge, but this can easily be remedied by packing from the frame so as to raise the floor above the tops of the wheels.



I have certainly seen ample to prove that, whatever position English makers may hold in their own markets, and that is difficult to prognosticate, they have no monopoly for export orders. Output alone can secure to them any advantage, for the French builders appear to be definitely behind our leading houses in that particular, and for commercial vehicles only.

(*To be continued.*)

HERE AND THERE.

THE other day we had an opportunity of inspecting a special 30-h.p. six-cylinder Napier car which has now been shipped by Messrs. S. F. Edge, Limited, to India. The car, of which an illustration is given herewith, is extremely quiet, and it is claimed to be able to travel at from four to forty miles per hour on the highest speed. The body is built of aluminium and is fitted with entrance doors at the sides. The upholstery

is of real leather, and is of the most luxurious description. Light dust curtains are attached to the sides of the canopy. A combined glass wind and dust shield is provided at the rear end of the body, the central portion of which can be opened if required, and there is also a glass wind shield over the dash-board in front of the front seat.

THE Duke of Marlborough has just purchased a 3¼-h.p. Clyde motor-bicycle.

THE United Kingdom Motor Tyre Manufacturing Company, Limited, has been registered.

THE Bromley (Kent) District Council's Surveyors have reported in reference to certain roads to be scheduled under the Motor Car Act.

THE South British Trading Company, Limited, are bringing out a "three-in-one" oil which is claimed to be useful for lubricating a wide range of machinery.

IN connection with the special course in January for the staff officers at the Staff College, Camberley, it is proposed to hold a Staff Ride, the cars of the Motor Volunteer Corps being used for the purpose.

THE "Boon" Variable Gear Syndicate, Limited, has been registered with a capital of £5,000 to acquire an invention relating to improvements in driving and gearing mechanism for motor-cars, and to adopt an agreement with Mr. A. W. Boon.

MESSRS. DONNE AND WILLANS, LIMITED, has been registered with a capital of £5,000 to acquire the business of a manufacturer and repairer of and dealer in motor-cars carried on by Mr. M. Donne, at 27, St. John's Square, Clerkenwell, E.C. The first directors are Messrs. R. St. J. Willans and M. Donne.

THE Resilient Hub (Jackson's Foreign Patents) Syndicate, Limited, has been registered with a capital of £5,000 to adopt an agreement with Messrs. J. E. Hodgkin and E. C. P. Scott, and to carry on the business of hub, axle, tyre, wheel, and lamp manufacturers, etc. The registered office is at 32, Victoria Street, S.W.

MOTOR PLANTS, LIMITED, is the title of a company registered with a capital of £10,000, to adopt an agreement with Mr. H. B. Graham and Mr. A. J. Smith, securing their services, and to carry on the business of manufacturers of and dealers in motors. The registered office is at Winchester House, Victoria Square, Birmingham.

FROM Messrs. W. Galloway and Company, of Gateshead-on-Tyne, we learn that the Stanley Motor Carriage Company are placing on the market for next season no less than five new models, three of them having the boiler in front under a bonnet. Perhaps the most interesting of all the new models will be a 20-h.p. touring car to seat five, with side-entrance tonneau body.

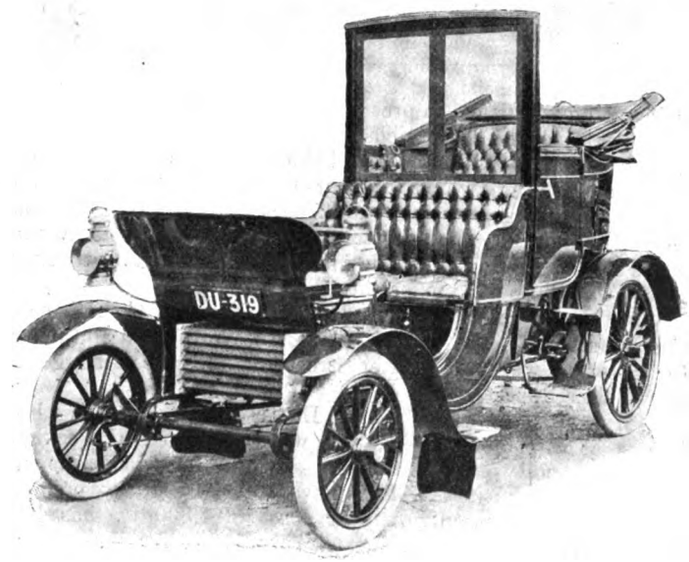
MR. J. W. ORDE has been to Douglas in connection with next year's motor racing in the Isle of Man.

THE floor of the garage should be kept free from oil as a precaution against fire, and also to save the tyres from damage.

MESSRS. HUMBER, LIMITED, have placed their contract for the supply of accumulators for the ensuing year with the Prested Battery Company.

AN automobile club has been formed for Harrogate. Dr. Ozanne has been elected president, Dr. Holroyd Pannal, treasurer, and Mr. W. C. Priestley, secretary.

THE business carried on by the Regent Street Garage at 151A, Regent Street, has been acquired by Messrs. S. F. Edge, Limited, and is now directly connected with 14, New Burlington Street, W.



THE Agricultural Handbook for the year 1905 contains articles of great interest and utility to agriculturists. It is edited by Messrs. C. R. Adeane and Richardson Carr, and is published at "The County Gentleman" offices.

AT the meeting of the Oswestry Town Council a letter has been read from the Great Western Railway Company, intimating that the company had it in contemplation to work the Oswestry branch by means of a rail motor service as soon as the necessary vehicles had been constructed.

DURING the last week or two the motor-'buses of the Isle of Wight Express Motor Syndicate, Ltd., have been flitting about the island. The ordinary fares charged will be: Sea View to Ryde, or *vice versa*, 6d.; Cowes or Newport to Ryde, 1s.; Sandown or Bembridge to Ryde, 9d.; St. Helens to Ryde, 7d.

PROFESSOR H. S. HELE-SHAW has resigned his position as head of the Faculty of Engineering at the Liverpool University in order to proceed to the Transvaal Colony, where he is undertaking the duties of senior professor of the new Technical Institute which is to be established there. He will leave England early next year.

SIR WILLIAM SELFE, judge of the Rochester County Court, last week awarded a labourer £21 damages and costs for injuries sustained through being knocked down and run over by a motor-car. His Honour held that the accident was caused by the defendant attempting to pass a string of dockyardsmen going home from work and not allowing sufficient room.

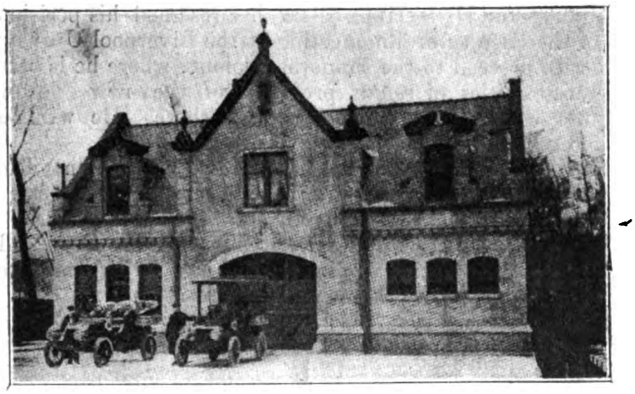
The above Illustration depicts a new design in Duryea Carriages recently built by the Duryea Company, Ltd., for Dr. Ca'verley, of Folkestone. The car is built on a standard chassis of 15 h.p., and is identical, so far as the front portion of the carriage is concerned, with the usual type. The rear portion, however, is constructed as a landaulet with fixed glass screen in front, the entrance being, of course, at the side.

THE Canterbury (New Zealand) Automobile Association has decided to co-operate with the Auckland Association in securing a reduction of the heavy charges made for the conveyance of motor-cars by steamer between the various ports of the colony.

Digitized by Google

THE Torquay Motor-Omnibus Company has been able to pay a dividend of 7½ per cent.

THE Motor Omnibus Trust, Limited, has been registered with a capital of £1,000, to carry on the business indicated by the title.



MR. A. MILLS has been elected captain, Mr. M. Blackwaller secretary, and Mr. Thistle treasurer, of the newly-formed Cardiff Motor Club.

THE Hozier Engineering Company, Limited, have secured the rights to fit the Simplex ignition, illustrated in the last issue of the *Journal*, to Argyll cars.

AN error respecting prices has been appearing in the Speedwell Motor Company's advertisement, the price of the 10-h.p. light Speedwell car being £10 more than was stated.

WE are officially informed by the Dublin, Wicklow and Wexford Railway Company that they are now running a steam lorry for the carriage of goods between Ferns station and Newtownbarry.

THE best private motor-car garage in Chicago is stated to be that of Mr. Shepherd. Situated in the rear of that gentleman's house in the southern part of the city, the garage is of an inviting appearance. On the ground floor are located the storing room, with accommodation for three or four cars, and repair shop, while in the upper storey are found the sleeping quarters of the mechanics and bath rooms. The lower floor is furnished with every modern convenience for the repairing of motor-cars save a lathe. The floor is of cement, laid on pressed bricks, while the

wainscoting is finished in pressed brick. Located in the garage is a turn-table and a spacious repair pit. Outside, at a safe distance from both the house and the garage, is located a 120-gallon petrol tank, which, of course, is underground. A pipe runs to the garage, with a shut-off cock attached to it just outside the building. If at any time the men desire to fill a tank while a car is inside the building, all they have to do is to attach a hose to the pipe and run it into the garage.

AT the last meeting of the General Purposes Committee of the Wrexham Town Council, plans were presented and passed for motor-car works in Chester Street for Messrs. H. Higginson and Walter Roberts.

MESSRS. E. AND H. HORA, LIMITED, who have long been known as carriage builders, and whose premises at Peckham cover between two and three acres, are entering with spirit into the automobile business. They have just erected new premises in the Peckham Road. A floor space of 4,800 ft. has been fitted with electric lifts, and heated throughout for the purpose of a second-hand showroom. In this department also they are arranging that second-hand cars for sale may be examined by an expert, who will submit to intending purchasers the exact state of the cars, engines, etc.—a new feature in the second-hand business which should be of interest to prospective buyers. The firm are also making bodies for motor-cars, in connection with which department they have a large plant of new machinery. Messrs E. and H. Hora are also taking up the agency for the new Hurtu cars, and are supplying half-a-dozen motor-'buses to Messrs. Tillings, Ltd.

THE makers of Peter's solid tyres are guaranteeing them for 10,000 miles run.

THE Warwickshire Chamber of Agriculture has been discussing the use and abuse of motor-cars, without, however, coming to any definite conclusion on the matter.

THE Birmingham Motor Show will be held from January 21st to 28th, 1905, under the management of Mr. Walter Cawood. A special section will be devoted to touring cars and tri-cars.

A CIRCULAR giving the conditions of the Long Distance Trials which may be carried out under the auspices of the A.C.G.B.I. has just been issued by the Technical Department of that organisation.

THE Dixi Motors, Limited, have despatched to Calcutta a 6-8-h.p. two-cylinder Dixi car, fitted with a four-seated side entrance body with doors to both back and front seats. It is for use up country, and is fitted with extra strong pneumatic tyres.

NINE hundred and forty-four gallons of petroleum which had been removed from Liverpool to Blackpool for use during the recent motor trials have been confiscated by the Blackpool magistrates, by whom Mr. James Hamilton, general manager of the Anglo-American Oil Company, was fined £1 and costs for having brought the petrol to Blackpool without the chief constable's permission. Mr. Roland Robinson, who defended, said there would be an appeal.

THE regulation prohibiting a locomotive to be driven along the highway without having on it a person competent to apply the brake was held by the Stratford Bench on Saturday to have been infringed in a case where, though there were two men on the locomotive, the brakesman, instead of being at the rear of the van where he could apply the brake, was with the motor. Only a small fine was imposed, it being stated that the vehicle had now been fitted with a pneumatic brake.

THE Birmingham and Midland Motor-Omnibus Company, Limited, has been registered with a capital of £60,000, to adopt an agreement between the Birmingham Motor Express Company, Limited, and to carry on the business of motor-car, omnibus, van, and cab proprietors, carriers of passengers and goods. The first directors are Messrs. W. J. Taylor, J. Jordan, T. Ottey, W. Roberts, and E. A. Olivieri, and the registered office is at Winchester House, Colmore Row, Birmingham.

THE inquest on Lieutenant Sidney Flavel, who died from injuries received in a motor-cycle accident, was held at Leamington the other day, and a verdict of accidental death was returned. From the expert opinion offered it was deduced that Lieutenant Flavel, who was picked up on the night of the 14th of November at the bottom of a hill near Warwick Castle, must have come down the incline very quickly, and that the machine skidded, causing him to come into collision with a lamp-post.

AMONG the pneumatic non-slipping and unpuncturable tyres lately put on the market is that known as the "Lucas," for which the Fabry Automobile Co., Ltd., are the sole concessionaires for the United Kingdom. This consists of a casing made of canvas and rubber, similar to the ordinary pneumatic tyre. The outside covering is made of "chrome" leather, which is firmly secured by a special process, and in addition is sewn to the "talon," which it completely covers thereby not only preventing the tread from coming off but materially strengthening one of the weakest parts of the ordinary tyre, and consequently increasing its life. The tread is fixed on the outside covering by means of steel rivets, and another "chrome" leather covering is added for the purpose of protecting the cover from the rivets. It is consequently absolutely impossible for the studs to injure the casing or inner tube. At the Versailles trials in February of the present year it was proved to be possible to drive at speed round corners on specially prepared greasy roads, and to suddenly apply the brakes without side-slipping; and it has also been proved to be possible to drive over nails or newly-metalled roads without puncturing, thereby not only saving much time and labour for repairs, but also expense. The "Lucas" tyres are made in all sizes, from 1,370 mm. by 120 mm. for heavy cars to 650 mm. by 55 mm. for motor-cycles.

CORRESPONDENCE.

THE USE OF THE ACCELERATOR—FOOT v. HAND CONTROL.

To the Editor of *The Motor-Car Journal.*

Sir,—I have read Mr. Percy Richardson's article in the *Journal* of the 10th inst. on the above subject, and I must say I cannot agree with him that the use of the foot accelerator is dangerous. The two makes of cars which I may claim to have had most experience with, namely Panhard and Mercedes, differ completely in their method of control. While Messrs. Panhard have always kept rigidly to the idea of the foot control, though introducing certainly a control on the wheel besides, which is totally ineffective as regards acceleration, the Daimler Motoren Gesellschaft have on the other hand steadily refrained from introducing a foot control. From the experience I have had of both these types of cars, I must say that the ideal form of control on a car would to my mind be a combination of the two. The Mercedes governor and throttle is so arranged that at whatever speed the motor is set to run by the hand throttle, the governor keeps the engine running constantly at that speed, provided, of course, it is not subjected to an overload. If therefore you are running in traffic and can set the car to run at say ten miles an hour and you suddenly wish to accelerate quickly, it is necessary to move the lever on the steering wheel, guiding the car through possibly very difficult traffic with one hand. The same applies to driving in the country, round corners and on winding roads. In practice a Mercedes car is guided entirely by the left hand, the right hand, which is usually the stronger, being reserved entirely for operating the throttle. If a foot accelerator were added to these cars, the control would be absolutely perfect. On the other hand, the Panhard system, which depends upon the use of the foot accelerator, possesses other disadvantages. In practice the control on the steering wheel is closed to such a point that when the accelerator is "up" the engine runs at its lowest possible speed, and in order to get any power from the motor at all it is necessary to depress the accelerator. The accelerator is, in practice, always down, causing the throttle to be open to its fullest extent, therefore, in Panhard driving the engine is either giving its maximum or its minimum power with practically no variation. In traffic this is handy, as London driving consists in alternate quick bursts and quick stops, but for country work or on winding roads, where the power of the engine exceeds that required, it is very trying to the foot and to the car, as it necessitates constantly drawing the clutch.

Summing up the advantages of both systems, it appears to me that the foot accelerator system possesses the great advantage of leaving both hands free to operate the steering wheel, which, after all, the lives of the driver and occupants of the car depend on, and that great acceleration can be obtained in the smallest possible time, and finally, that the operation of putting on the brake must immediately release the accelerator owing to the fact that the same foot operates both pedals, and thereby renders the engine free from the dangers of racing. The system of hand control has the great advantage that the motor can be made to run at the will of the driver at any constant speed from minimum to maximum. Both systems appear to me to possess advantages and disadvantages, which, if combined, would give a control that would be altogether safe and satisfactory. I believe I am right in saying that M. Jenatzy's Mercedes in the Gordon Bennett race was fitted with a foot accelerator which gave him very great advantage over other competitors, though I admit that racing conditions are altogether different to touring.—Yours truly,

J. E. Hutton.

To the Editor of *The Motor-Car Journal.*

Sir,—I have read with interest Mr. Richardson's article on the above subject. Personally, I do not see there is any great question over the matter. The foot control has many advantages, so has the hand control; the solution therefore seems to me to be a combination of the two, working independently or otherwise. In the four-cylinder 15-20-h.p. Brooke cars we arrange the governor to cut out at 500 r.p.m., above which speed the foot accelerator has to be used, and if this is depressed the hand control can still be used for all speeds, but if the foot accelerator is not depressed then the hand control can be used only for speeds below 500 r.p.m. of the engine; this means, that for all speeds above this the foot accelerator has to be depressed.

In our 1905 28-35-h.p. cars I think we have a still better method; it has the same action as in the 15-20-h.p. above described, but is so arranged that the hand control has an extension which eventually acts on the governor and increases the tension on the spring, so increasing the governed speed of the engine. I believe this is the ideal control. Yours truly,

Maudsley Brooke.

To the Editor of *The Motor-Car Journal.*

Sir,—Referring to the question as to foot or hand control of the accelerator, we are pleased to say that we agree very much with Mr. Richardson that the control of motor-cars should be simplified as much as possible, and have throughout followed this principle to the fullest possible degree in the construction of Duryea carriages. By the accelerator is meant, we take it, the mechanism by which the governor can be more or less put out of action, but in our vehicles we use no governor at all, thus avoiding a certain number of parts and placing the full control of the engine more directly in the driver's power. Then we agree with Mr. Richardson when he says that a human being is only possessed of one pair of hands and one pair of feet, so, whilst one hand will be required for working the gear-changing and brake levers, and the other must necessarily be always on the steering handle, we place the engine control, or what would be equivalent to the accelerator in other cars, *i.e.*, the throttle, in the steering handle itself; thus the driver has not even to move a finger to grasp a lever, but simply raises or lowers his wrist as he requires to advance or retard speed of the engine and car. This makes the simplest possible control, and places both the speed and the direction of the car entirely in the one hand, which of necessity must always be grasping the steering handle, so that the control is not only of the simplest possible character, but is as instant in action as thought. You will gather from this that we are entirely in favour of hand control. —Yours truly,

Henry Sturmey.

To the Editor of *The Motor-Car Journal.*

Sir,—With reference to Mr. P. Richardson's article in your last issue on foot v. hand control, I quite agree with him that a foot control is infinitely ahead of the ordinary hand levers on the steering gear. I should like to point out that one English maker is at the present time fitting a foot throttle actuated by the withdrawal of the clutch pedal, which up to the present time has proved very satisfactory indeed and is most convenient in traffic. But what I cannot understand on the part of the large firms is that so far they have put nothing whatever on the market in the way of a foot accelerator worked on the combined throttle and ignition system of control as fitted by an English firm in the form of a hand lever, and which works as well as can be wished. But it has the disadvantage of requiring both hands, one on the steering gear and the other on the throttle lever, and, as Mr. Richardson remarks, an ordinary human being is only possessed of two hands and two feet; it leaves the horn to be worked as best it can. The foot control would do away with this difficulty, and, to my mind, would be a great improvement. I am of the opinion that in a few years we shall see cars driven entirely on two or three pedals, and sincerely hope I may "be there to see."—Yours truly,

Charles E. N. Storr.

MORE ENGINE TROUBLES.

To the Editor of *The Motor-Car Journal.*

Sir,—Will you give me your opinion on the following trouble. My two-cylinder Aster engine, when working with the car at rest, makes a most peculiar hammering metallic noise when running at a fair rate against the governor, but not when "raced" or run very slow. This "tinny" hammering occurs with every beat of the engine when the back cylinder trembler is held out of action and does not occur at all when the other trembler is held down. The same noise occurs intermittently when on the road, and on all three speeds, also invariably whenever the clutch is withdrawn for gear changing. The engine has just been carefully overhauled here by a good firm, in an endeavour to locate the noise; they report the engine in good order throughout, and are, like myself, puzzled. All the usual tests have been tried and every part of the engine and connections seen to.

I imagine the trouble has something to do with ignition.—Yours truly,

Perplexed.

[We think that "Perplexed" will find the trouble in the inlet valves. The fact of not having the springs in each case at the same tension would cause a slight hammering in one cylinder and not in the other. This would not be noticeable at a high speed with the throttle open, but would when closed, the suction causing a partial vacuum in the inlet pipe, thereby aiding the valve to close more quickly, and having the tendency to hammer the valves, more especially if the springs are somewhat strong. We should advise trying a little weaker spring on the cylinder which appears to cause the trouble.]

To the Editor of *The Motor-Car Journal.*

Sir,—I should be very glad if some of your many readers could assist me in the following matter. In consequence of the frost my cylinder was burst. I took advantage of the accident and put in a new one, a little larger in the bore, viz., 4 in. instead of 3½ in. After being completed I find my power on the low gear very much lower than previously, owing, I think, to the engine running slower. The top speed is very much the same, but more powerful. The engine also runs very irregularly, sometimes running down, then racing away without any alteration in the petrol or sparking. The water circulation is very unsatisfactory, and causes overheating, also premature firing. The cooling is done by radiator. The water supply up to the time it reaches the pump is right, but when it leaves the pump and reaches the water jacket appears to be instantly generated into steam. Therefore no water gets round the cylinder. The steam appears to pocket in the return tube, which has to travel down below the outlet of the cylinder some 16 inches, then rises again to top of the tank some 3 or 4 inches higher than the cylinder level. I may say the engine is fixed on back axle and tanks under the bonnet in front. The car is of French build, and is eighteen months old. The lubrication is, I think, at fault: previously it was from the crank chamber and very satisfactory indeed. Now a lubricator is fixed on the side of cylinder, the oil afterwards being returned

Digitized by Google

in a small well on top of the chamber into which the lower end of the piston dips. The silencer is very defective, consisting of a case, 15 in. long by 5 in. dia., in which are six half-inch tubes, perforated, running the whole length and open at each end. I shall feel very grateful for any suggestion to remedy the above.—Yours truly.

A READER OF THE JOURNAL FROM THE FIRST ISSUE.

THE COST OF RUNNING.

To the Editor of *The Motor-Car Journal*.

SIR,—As your correspondent "J. G. R.," and others, might be discouraged by the figures I recently gave showing the cost for running my car for one year, I should like to add a few particulars to those already supplied. The item "repairs" included the addition of two sprags, and also two rubber rollers, one fixed on each side of the car frame for the purpose of preventing the front wheel covers from being injured by coming into contact with the spring hinges when going too sharply around corners. "Repairs" also comprised a pair of guards to prevent mud dropping from the splash boards into the band brakes; also a zinc covering to flywheel to prevent the oil being thrown about the inside of the bonnet; also the replacing of two broken springs of the back wheels. Mine is a French car, and I think the springs must have been rather too light for our bad roads. I have therefore had thicker leaves substituted and now carry spare straps and plates for repairing broken springs. I have also smashed one of my splash-boards twice. Once it was my fault and the other time it was not, but I paid for both. Accessories include a clock at a cost of 30s. and an odometer for the same sum. Tyres include £8 8s. for Samson non-skids on hind wheels.

"J. G. R." will see, therefore, that some of my expenses were not absolutely necessary—merely luxuries; and while on the subject of repairs I would suggest that it is not always the biggest people who do these most satisfactorily. The cycle agent or an intelligent ironmonger will frequently do the work better than the Blundering Motor Company, Limited. He gives his personal attention to it, whereas at the company's works some apprentice may be deputed to experiment on your car, while the fitter is sent away to take the orders of the last arrival, who "can't wait." As to insurance, the chief contingencies to provide against are fire and third party claims, and £5 a year should be sufficient to cover these in the case of any moderate sized car, such as a 10–12-h.p. Some companies stipulate that the car owner shall pay the first 40s. or 50s. in case of damage, etc.: the result is that I have had to make good my own damage on two or three occasions, and my rather large premium has been clear profit to the insurance company. Other companies will accept a very low premium if the car-owner will pay the first £10 of everything insured; for instance, a premium of £7 10s. is reduced thereby to £3 3s. This seems to point to the conclusion that as it is so unlikely that any damage or claim beyond £10 will occur, it may be hardly worth while to insure at all. With regard to rent, enquiry at all the stables and garages in the locality will sometimes result in payment of a much lower rent than formerly, or, in your present landlord offering to accept a considerable reduction, as in my own case. In short, with a little trouble and care a car can be run at a very moderate sum. If car owners were to give others the benefit of their experiences more frequently I think we could with better prospects face the crowd of car-sellers, insurance agents, repairers and garage owners, who all take so much interest in our welfare.—Yours truly,

S. C. G.

SUNRISING HILL CLIMB.

To the Editor of *The Motor-Car Journal*.

SIR,—My committee regret that an error has been discovered in the particulars of the above competition, recently published, which affects the result.

The Argyll car when first weighed was 19 cwts. 1 qr. loaded, and 15 cwts. 2 qrs. unloaded, leaving 4 cwts. 1 qr. only as the weight of the four passengers. As the passengers did not average the ten stone required by the rules, a boy was taken on the car, which then weighed, loaded, 1 ton and 3 qrs. The alteration from 19 cwts. 3 qrs. to 1 ton 0 cwt. 3 qrs. on the weighing card, which was filled in with ink pencil, became indistinct owing to the rain, and the weight of the car was read as 1 ton 9 cwts. 3 qrs., and was taken as such when working out the handicap. On the basis of the corrected weight, the Daimler car driven by Mr. Percy Martin takes the first place, and I shall be obliged if you will publish this correction in your next issue. I may add that on discovering the mistake Mr. W. H. Cook at once placed himself in the hands of the committee, and the prize will therefore go to Mr. Martin.—Yours truly,

A. G. JOHNSON, Hon. Sec., *pro tem.*

WINTER PRECAUTIONS.

To the Editor of *The Motor-Car Journal*.

SIR,—Replying to "W. J. L.'s" enquiry in the last issue of the *Journal*, many motorists heat their motor stables by means of a coal stove. While this can be done, there is obviously a good deal of danger involved in an open fire in a shed containing a car charged with petrol, for, if the tank should ever become leaky without the owner's knowledge, an explosion would be almost certain to result. Obviously when the motor house is located near a building provided with a steam or hot water heating system, the problem is a comparatively easy one, as radiators or flues are then readily installed in the stable and connected with the heating system of the building. Where the owner's residence is not equipped with any of these modern heating arrangements, and where the installation of such a system is impossible, or inadvisable for any reason, the stable must necessarily be heated by means of a stove. In such a case, however, I consider it advisable to locate the stove in a partitioned-off corner of the stable, or in an addition thereto, and to simply lead the heated air from round the stove through the shed containing the car. With such an arrangement, it is absolutely impossible for inflammable vapours to reach the stove, and all danger of fire or explosion is eliminated. The heating efficiency of the stove under such conditions may not be so great as if it were placed directly in the stable, but the latter arrangement is infinitely the safer one.—Yours truly,

T. ALEXANDER.

PETROL CONSUMPTION.

To the Editor of *The Motor-Car Journal*.

SIR,—In the *Journal* of the 3rd inst. there was printed Mr. Beaumont's commentary on the recent "Light Cars Trials." I wish someone would explain why the two cylinder-cars, both Swift and Humberette, consumed so much more petrol than the single-cylinder cars of the same make. The two-cylinder Swift did only 23·6 miles per gallon and the single-cylinder Swift did 38·8 miles; does the increasing the number of cylinders, without increasing the h.p., increase the petrol consumption? Another point in the trials was that the single-cylinder Swift was third in the hill-climbing, while the two-cylinder was seventh; contrary to what one would have anticipated, the i.h.p. of each being the same.—Yours truly,

BERNARD NORTON.

THE EFFECT OF EXHAUST GASES.

To the Editor of *The Motor-Car Journal*.

SIR,—Perhaps an experience of mine may serve as a warning to some of your readers. One morning following a hard frost in the night I went to draw the water from a motor-car kept in a brick shed with no means of warming. Preparatory to taking the plug out I started up the engine, intending to warm the water so that the tank, circulating pipes, and water jacket should drain quite dry. The engine had been running about ten minutes when I began to feel light-headed, and things seemed blurred, and while wondering what had happened I began to feel dizzy and to rock about on my feet. I had the presence of mind to make a dash for the door and throw it open, and get out into the open air. On entering the car-house I had carefully closed the door behind me, thus precluding any fresh air getting in, and no doubt was being slowly poisoned by the exhaust gases.—Yours truly,

W. F. F.

SELF-STARTING MOTORS.

To the Editor of *The Motor-Car Journal*.

SIR,—After being accustomed to the advantages of a self-starter, I find it most inconvenient to be without one on a four-cylinder Darracq I recently purchased. I am told one cannot be fitted in connection with non-trembler coil, but do not credit the statement. By means of four pushes, which, when pressed, connect accumulator, through engine, to coil, I am able, on the pushes being released and connection broken, quickly to

(*The Motor World.*

Digitized by Google

cause a spark at each plug; but, try as I may, I cannot get engine to start, though I can get back fires. Can you or any reader help me? After using a self-starter it is like going back a century to be compelled to turn the starting handle after a short stop. On my old car I have dozens of times started without the use of handle after as many hours' stoppage.—Yours truly,

VIATOR.

[It is very doubtful if the self-starting can be accomplished with the non-trembler coil, as the engine usually stops with one piston half up the compression-stroke and the other half way down the explosion stroke; both of these would equal approximately the same compression. Unless a continuous spark be obtained it would be almost an impossibility to fire this half-compression charge. It could no doubt be accomplished by means of an auto-trembler, but the more satisfactory method would be a controller coil.]

CLUTCH TROUBLES.

To the Editor of *The Motor-Car Journal*.

SIR,—Could you or some of your readers advise me as to the best means to get a clutch to hold? It is a leather-faced one on a 10-h.p. car, and appears to be thoroughly saturated with oil. I have repeatedly washed it with petrol without effect, tightened spring, and lastly used French chalk and powdered resin with short-lived results. The leather does not appear to be unduly worn, and has not been in use two years yet.—Yours truly,

A. M.

[There is without doubt something wrong with "A. M.'s" clutch, as powdered resin would certainly have effect. We would suggest that the leather is either worn sufficiently to allow the rivets to bear, or that the clutch is prevented from going quite up by coming in contact with some metal portion inside—probably the end of the spigot bearing.]

AN INTERESTING MOTOR QUERY.

To the Editor of *The Motor-Car Journal*.

SIR,—Your correspondent "Inquisitive One" wishes to know the reason of a petrol engine usually running better at night than through the day. We believe the reason is very simple—that it is owing to the extra moisture in the air at night. This has been proved in the experiments and tests we have carried out with the "Economic" carburettor, which is a carburettor for taking in a small amount of water with the petrol. When the carburettor is started in the ordinary way, and the water gradually turned up to a limit, the motor gives greater power; beyond that limit it slows down. Besides giving more power it keeps the cylinder very much cooler—so much so that air-cooled cylinders of fairly large size can easily be kept cool. When the water is introduced the sound of the engine is distinctly different—approaching nearer to that of a steam engine. We believe the theory to be:—The water is vapourised, so reducing the temperature, and therefore the pressure of the explosion at the commencement; but the expansion of the steam formed causes the pressure to be longer—a higher general level for the whole stroke—and, of course, it may be said that at the high temperature in the cylinder dissociation would occur, but time has to be considered in this, for it must take some time before the water is converted into steam, and must take longer time for it to be separated into oxygen and hydrogen. We think the above considerations indicate the reason of the better working of engines at night.—Yours truly,

THE ECONOMIC COMPANY.

THE MOTOR INDUSTRY AND THE CLUB.

To the Editor of *The Motor-Car Journal*.

SIR,—Absence in Germany has prevented my writing to you until now to correct certain mis-statements which have appeared in some of the motor journals. I wish to point out—

(a.) That the Automobile Mutual Protection Association includes over fifty trade members who do not belong to the Society of Motor Manufacturers and Traders;

(b.) That the younger body, the Society of Motor Manufacturers and Traders, represented only about one-third of the firms interested in motoring—many firms have joined neither body;

(c.) That the published lists of elections during the past season show accessions to the A.M.P.A. largely to exceed those to the Society of Motor Manufacturers and Traders during the same period;

(d.) That the sub-committee of the A.C.G.B.I. did not invite representatives of the older trade body, the A.M.P.A., to meet them, but accepted ex parte statements from representatives of the Soc. M.M. and T.;

(e.) that the A.M.P.A. has no control over, or power to ask patronage for, Messrs. Cordingley's Royal Agricultural Hall Motor-Car Exhibitions;

(f.) that the extension of club patronage to Olympia, on the ground that the show there will be the more representative, is directly opposed to fact as regards the commercial vehicle section, which I gather it is not the desire of the club to ignore or to prejudice.

I submit that this procedure is calculated to widen a breach rather than to conduce to a fusion of interests.—Yours truly,

E. SHRAPNELL SMITH

TREMBLER COILS.

To the Editor of *The Motor-Car Journal*.

SIR,—I have just purchased a Carpentier trembler coil, size of case 7½ by 6 by 3, made by Dubois, of Paris. I have fitted it on my 8-h.p. single-cylinder car. I can get plenty of sparks from the trembler and from the plug when I turn the handle slowly, but when turned very quick the spark at the plug is small.

I cannot get the engine to start. I have screwed the contact screw down hard and have tried it in the usual place. Must I exchange my make and break for a wipe contact?—Yours truly,

COIL.

[Make and break contact breakers are more suitable with coils that have no trembler, as in the Darracq cars. If used with a coil fitted with a high speed trembler such as the Carpentier, it is not always possible to obtain a satisfactory result. The speed of the engine does not allow the contact to remain sufficiently long to get the full value from the high speed trembler. A wipe spark would remove the trouble. We have made experiments with high speed trembler coils of various makers on an 8-h.p. car fitted with a make and break contact. With two of these coils it worked well, with the other it worked in the same manner as described by our correspondent, whilst all three coils were the same when used with a wipe contact. Therefore it would not be correct to assume that a high speed trembler cannot work well with a make and break contact; it depends on the mechanical working of the actual trembler in use.]

CHARGING ACCUMULATORS.

To the Editor of *The Motor-Car Journal*.

SIR,—I should be glad if you, or any of your competent readers, would advise me as to the best way of charging the accumulator of my two-cylinder car from thirty-two E.P.S. cells with smallest waste and at least cost. Could it be done by coupling two of the cells to the accumulator, or should I couple three cells and insert a small resistance? I do not wish to have a lamp in use all the time if it is not necessary.—Yours truly,

ELECTRIC.

[To recharge a 4-volt accumulator from cells forming part of a lighting set, it is necessary to connect up to three cells of the large set, and put a resistance in series with the accumulator being charged. Two cells would not be sufficient, because the voltage will only balance with the small accumulator, and three cells would be too much. Therefore the resistance is necessary. If a small ammeter is connected in the circuit, the amount of the resistance can be regulated to obtain the right charging current. It is advisable to charge from those cells in the large set which are used as the spare cells, these being, as a rule, underworked, and charging from them should make no difference to the whole set when it is in use. This method of re-charging is the most efficient, as there is practically no waste of voltage, and it is also very regular and certain. Care must be taken to connect the positive terminal of the 4-volt accumulator to the positive pole of the accumulators, which is usually painted red. If the connecting bolts of the E.P.S. cells are loosened to make connections, they should be well tightened up after charging, as loose connections heat up and cause trouble.]

QUERIES RE WOLSELEY ENGINE.

To the Editor of *The Motor-Car Journal*.

SIR,—I am having a little trouble with my 10-h.p. Wolseley car. It has been running well up to about a week ago, and as the engine was losing power a little, I ground all the valves in, and now it is worse than before. If any reader of the *Journal* has had the same trouble, I should be obliged if he would let me know, through the valuable *Journal*, how often the exhaust and inlet valves ought to be replaced. I find one inlet spring to be much weaker than the other, but I don't think that has anything to do with it, as the engine has run well with it before.—Yours truly,

PUZZLED.

[Undoubtedly the trouble of "Puzzled" is caused by the tappet screws under the exhaust valves giving too much lift, so as to hold them slightly off their seatings. By grinding in it would slightly lower the valves, bringing them in contact with the adjusting screws in the end of the lever which actuates them. The inlet valve springs should both be as near the same tension as possible. With regard to the renewal of valves, this is a point which must be left for discretion, as some engines may burn a valve in a few journeys, while others may run for years.]

INVICTA ACCUMULATORS.—In answer to a Belfast enquirer, the makers of these accumulators are La Société des Accumulateurs "Invicta," 5, Rue Deves à Neuilly, Paris.

SERVICE AT SOLWAY.—We shall be glad to have the address of the Workington syndicate that proposes to inaugurate a motor-car service along the Solway coast in the spring of next year.

MOTOR-CABS.—Following the names given last week, we mention the N. A. G. Aut mobile Company, 106, Great Portland Street, W., as being able to supply motor-cabs for hotel and station work.

NON-SLIPPING TREADS.—Messrs. Mann and Overton, referring to Mr. Drinkwater's letter in our last issue, say they have never had a complaint from the users of any of the thousands of bands they have supplied. They do not think the non-skids had anything to do with the tyres bursting.

Digitized by Google

THE BRITISH AUTOMOBILE INDUSTRY.*

By Henry Sturmey.

The 1,000 miles tour of the Automobile Club in 1900 did wonders in its influence upon public opinion, and during the twelve months following there was a great increase in the demand for motor-cars. Not only were the great majority of the English cars of that date little better than experiments, but practically no manufacturers were in a position to supply, except only to a very limited extent. The result was that people who brought cars back with them from the Continent found a ready sale for them, and many enthusiastic motorists of that day sold their foreign cars in England, after a season's use, for more money than they had paid for them, for they were undoubtedly better in many respects than the home product. These gentlemen were generally rather pleased than otherwise to tell everyone of their smartness, with the natural result that others sought to do the same, and as the desire to possess a car was now rapidly growing amongst the English people, the French manufacturer soon found an enormous new market opened to him, and dealers flocked to place orders with him for the supply of British needs, with the result that, the sale of his output assured, he increased his production enormously. For a time all went well. In the seasons 1901 and 1902 the demand here was greater than the supply. Dealers demanded enormous premiums for what cars they could deliver, and both they and their customers thought themselves lucky to get cars at all. For 1903 they again doubled their orders, and the French industry once more responded and expanded, and they talked of their big profits, so that long before the end of the season new firms for importation and dealing were being formed in every direction, and whilst capital, with but few exceptions, carefully tabooed the home industry, importation and retailing were looked upon as the only means of making money in the motor business, with the result that to-day this branch of the industry is enormously overdone. Garages and motor depots have sprung up like mushrooms. Every street in London pretty well has one, and many several. From Baker Street Station to the Angel at Islington, for instance, they fairly jostle each other in places, and the cry of "bad times" is heard in the land, and little firms with an odd £1,000 or so capital have filled themselves up with foreign goods to the immense benefit of the continental manufacturers, and then, finding the public are not scrambling for their goods, they have a scramble amongst themselves to get quit of them.

Although the trade in foreign cars is, as above stated, very much overdone, and British trade has received the cold shoulder in its own land, it has not stood still, and is, indeed, in a far stronger and healthier position to-day than could have been expected with the circumstances against it. In spite of all odds it has made steady and even rapid progress. In the four and a half years since the 1,000 Miles Trials it has indeed done wonders. There were at that time only two British firms organised for manufacture. I give below the progress made by representative British firms who have been in business upwards of three years, and I think you will admit the result is satisfactory.

No.	1901-2.	1902-3.	1903-4.
1	100	120	233
2	100	110	140
3	100	160	160
4	100	200	360
5	100	100	200
6	100	200	485
7	100	305	590
8	100	240	424
9	100	142	335
10	100	109	199
11	100	280	378
12	100	100	156
13	100	252	563
14	100	379	598
15	100	166	240
16	100	150	250
17	100	550	233
	1,700	3,561	5,544

In the above table the business done by each of the seventeen firms dealt with in 1901-2 has been taken as a unit, and the business done in the two following years figured in relation thereto. It will be seen that in every case there has been a heavy increase as between last year and 1901-2, and with a single exception the increase last year is considerably greater than either of the two previous years, the only case in which this is not the case being No. 17, in which a far greater advance was made on the first year's work in the second than by any of the rest, the drop in the third year being due entirely to internal troubles, which hung up production for some months in the spring of the year. The seventeen firms taken virtually represent all the makers in the light motor industry who were making cars commercially in 1901-2. I have taken no account of motor-cycle making firms, or of the commercial vehicle trade, nor have I included the business done in the two latter years by a number of firms who have entered the trade since 1901. By adding the totals it will be seen that the aggregate trade of these British firms during 1902-3 showed an increase of 109·4 per cent. over the trade of the previous year, whilst a slightly greater increase over that is shown for the season just expired; last year, indeed, as compared with 1901-2, showed an increase of 226·1 per cent. Now, the business done by the automobile manufacturers of France has been recently stated to be approximately:—

1901	£1,200,000
1902	£2,400,000
1903	£4,000,000

It will be seen by comparison of these figures that the increase in trade of these seventeen British firms alone, excluding the additions to the industry in the two latter years, shows a higher percentage of advance than does the aggregate French trade.

I have not given in the above figures any figures with reference to the heavy commercial vehicle branch of the industry. Undoubtedly, in this branch of the trade England at present occupies a higher position than any other country, and a very large trade has been done.

Another matter that has been thrown at us has been the comparative smallness of our exports; but we are not so behind as some people seem to think. In the first place, a country which cannot nearly supply the home demand can scarcely be looked for to send much abroad; in the second place, when comparing French exports with British exports, it must be remembered that the great bulk of French exports are to this country, where there is a huge demand and an absolutely free market, whereas, not only by tariff, but by sentiment, British manufacturs are virtually excluded from the Continent, and what trade they have to do is done everywhere in face of a tariff, as there are no other free markets outside of this country. Now, let us look at a few figures. The French exports of motor-cars in 1901 equalled £631,281, but there are no figures to show where these were sent. For the years 1902 and 1903, however, we not only have available the total export returns, but also the returns to this country, and we find that in 1902, whereas £1,208,760 worth of cars and parts—that is just over one-half the total French product for that year—were exported, all but £357,005 in value came to this country, whereas in 1903, out of a total product of £4,000,000, £2,035,680 were exported, and all but £399,806 were "dumped" upon us. The returns for the first ten months of 1904 show a total export from France of £2,240,000, equivalent to £2,688,000 for the full year. I have not the proportion, however, of these exports to this country, but it will be noticed that there is nothing like the proportionate advance, or even the actual advance, which is shown in the French exports of the four previous years. Coming now to our own exports, we find that, whilst we have no returns for 1901, British exports in motor-cars and parts in 1902 were £172 143, and in 1903, £343,817. Practically the whole of these went to other countries than France, and by a comparison with the figures of French exports for these two years, it will be seen that, whilst the French exports to other countries than England increased only 11·9 per cent. in 1903 over 1902, our own exports during the same period increased no less than 93·9 per cent., whilst in the second year the total of £343,817 will compare very favourably in view of the respective dimensions of the total industry—in actual figures with the £399,806 of the French business in the same field during the same period.

As to the actual dimensions of the industry here to-day, I have ascertained that the largest number of hands employed by any one firm in this country is 1,300. The smallest amongst the seventeen firms mentioned above employs 100, but as, whilst the larger firms make virtually everything on the premises, including the bodies, very few, if any, of the smaller houses manufacture the bodies, and many get quite a large proportion of the total car manufactured in other engineering shops, so that the figures given are actually much under the mark. The seventeen firms above alluded to, however, to day, employ 6,120 hands, and if we take the heavy commercial car branch of the industry to employ another 2,500, and the motor-cycle and body makers at least as many more, we shall have a very respectable number of persons in this country dependent upon this industry, in addition to which the number of persons engaged in the sale of cars all over the country, in repair work, and in garage work generally must aggregate to a very considerable number, and in addition to this we have those, a large portion of whose work in general engineering shops is devoted to the production of parts and material, so that I do not think I am at all ouside of the mark when I say that we must have at least 20,000 persons directly and indirectly engaged in the automobile industry in this country to-day, a result which, when the short time we have been seriously at work is considered, is little short of marvellous.

In those few instances where proper financial support has been given, not only is rapid progress being made, but most satisfactory and substantial profits are being returned to those who had the enterprise to take the plunge—facts which, when once known, should refute for ever the doleful refrain above alluded to. The 35 per cent. dividends of the Hozier Engineering Company are fresh in the minds of readers of the automobile press, and these should be substantial enough for anyone; yet this firm, which is now the second largest in the United Kingdom, was barely in existence four years ago, and only a day or two since I met a man who was sorrowfully bewailing that he had failed to take up the shares to which he was entitled under an amalgamation when it was formed, his reason for not doing so being that "no one had made any money at it" then! The big profits of the Darracq Company over the past three years, culminating in a 20 per cent. dividend and £50,000 taken out of profits for extensions, are also now a matter of history; and although in this case it may be said that the work is done in France, I would point out that, whilst

* From a Paper read at the A.C.G.B.I. on December 8th, 1904.

Digitized by Google

that is true, the sales—or, at any rate, the bulk of them—have been made in England, whilst the capital financing it is English. Most of our motor firms, however, although limited companies, are not public ones, so that it is not possible to know their profits, but I can say with absolute certainty that in all cases where sufficient capital is available to get a large enough output, the profits that are being made are substantial. I take it no one will query, for instance, that the Napier and the Wolseley firms are profitable undertakings, although they do not publish it on the housetops, and I say without hesitation that a million could be placed in the motor industry to-day—without the establishment of any new firms—with very little possibility of any of it going astray and the absolute certainty that very substantial returns would result.

THE LIGHTING OF ROAD VEHICLES.

THE memorandum showing the views of the Motor Union on the subject of the lighting of road vehicles prepared in connection with the deputation to the Home Office on Tuesday set forth :—

1. Pending the passing by Parliament of a Bill providing that all vehicles throughout the country shall carry efficient front and rear lights, the Motor Union venture respectfully to request that the Home Office shall take the following action :—(a) Amend the model bye-law printed by order of the Home Office for the guidance of Councils in making bye-laws under the Municipal Corporations' Act and the Local Government Act, so as to provide that after dark all vehicles shall show a red light in the contrary direction to which they are proceeding. The present model bye-law provides that vehicles shall carry a lamp or lamps so constructed as to show to the front a white light visible within a reasonable distance to persons meeting or approaching the vehicle. Vehicles are not required to show a red light to the rear except when they are carrying loads projecting more than six feet. (b) Circularise the local authorities who have power to make bye-laws, suggesting that they shall adopt the new model bye-law providing in all cases for the carrying of a rear red light. (c) Bring special pressure to bear upon those local authorities whose present lighting bye-laws exempt slow-going vehicles from carrying lights at all, or which exempt all vehicles from carrying lights during the summer months.

2. In support of the above requests it is urged (a) That since the model bye-law of the Home Office was settled there has been a great alteration in the conditions of road travel by the increasing use of the motor-car. The introduction of a fast travelling vehicle upon the road has rendered it necessary in the public safety that the position of all other vehicles shall be clearly indicated at night by lights. Such indication is particularly required in the case of slow-going vehicles, which are necessarily overtaken and passed by the faster traffic. (b) Serious accidents have been caused by the neglect of slow-going vehicles (which on dark and unlighted country roads usually occupy the centre of the carriageway and are often on the wrong side of the road) to carry efficient lights, and such accidents are likely to increase in number unless some efficient means of lighting the slow-going vehicles is insisted upon. (c) The need for detecting unlighted vehicles upon the road has rendered it necessary for motor-cars to carry powerful lamps. The glare caused by these lamps has been seriously objected to. If all vehicles were required by bye-laws to indicate their position after dark by lights, the necessity for automobilists to carry such powerful lights would be considerably reduced. (d) It is most desirable that there shall be uniformity of regulation. A main road in twenty miles may pass through the area of three or four authorities having power to make bye-laws. Pending a statutory provision, such uniformity can only be secured by the action of the Home Office.

3. For these and other reasons the Union desire in the strongest possible way to urge the Department to make strong representations to the councils of counties and boroughs in England and Wales to induce them to adopt an efficient and satisfactory bye-law providing that all vehicles shall carry a lamp or lamps, so constructed and capable of being so attached as when lighted to show a white light in the direction in which the vehicle is proceeding, and a red light in the contrary direction, such lights to be visible within a reasonable distance to persons meeting or approaching or overtaking the vehicle.

CLUBS AND ASSOCIATIONS.

SCOTTISH.

THE annual dinner of the members of the Western Section of the Scottish Automobile Club took place in the St. Enoch Station Hotel, Glasgow. Sir Matthew Arthur, Bart., presided, and the croupiers were Mr. John Adam and Mr. Henry M. Napier. The company, which numbered about 150, included the Right Hon. Sir J. H. A. Macdonald, K.C.B., Lord Justice Clerk of Scotland, Count Louis de Clercq, Right Hon. Sir Herbert E. Maxwell, Bart, M.P., Sheriff Fyfe, Professor Archd. Barr, Professor Dawson Turner, Bailie M'Innes, Shaw, ex-Preceptor Gray, D.L. ; Messrs. Hugh Reid, D.L. W. Weir, W. Hepburn, N. P. Brown, H. W. Block, J. B. Shanks, J. W. Murray, Fred Lobnitz, J.P., F. G. Buchanan, J.P., John M. Ross, Arthur Hart and Robert J. Smith, hon. sec. The loyal and patriotic toasts having been honoured,

The Chairman proposed "The Scottish Automobile Club." Given good roads and good weather, he did not think there was anything more exhilarating after a day's work or sport than the run home in a car through the fresh air. Enthusiasm seemed characteristic of motorists. The Western Section of the Scottish Automobile Club at its formation in 1902 had a membership of 33, a year later this had increased to 113, and it was now 320. The principal club events of the year had been the very successful Glasgow to London trial in May, when about 30 different makes of cars competed ; the Lanark hill climb in September, and the anniversary run in October, in which 100 cars took part. The Western Section had recently suggested, in the interest of the industry, that the Glasgow to London trial should be replaced by one covering hilly roads in the Scottish Highlands, and this proposal, which was still under consideration, had met with strong support.

The Right Hon. Sir John H. A. Macdonald, Lord Justice Clerk, the president of the club, replied. Referring to the Automobile Act, he remarked that the fate of automobilists lay only eighteen months ahead. When the Act was passed it was thought that by restricting it to three years they would get better terms at the end of that time. He hoped it would be so, but he was certain that if they did not behave themselves they might get very much worse terms than they had already got. His Lordship added that he had long foreseen that mechanical traction was not to be for mere amusement or for the rich; it was to be of vast benefit all over the country, if it was properly organised. They would be doing a much more patriotic work in encouraging the running of vehicles for the conveyance of goods and passengers than in merely running pleasure vehicles. He believed that commerce would enormously benefit from the extension of the automobile industry, and it would enable people to make a living, which they could not do now in many parts of the country. They might

The Firefly Motor Company, of Croydon, has sent us the accompanying illustration of a novel home-made motor-car. It is built up of 3 dining-room chairs, 3 wine cases, part of dining-room table, a tablecloth, two dustbin lids, a walking-stick, and a tray.

rely upon it that if only we went in boldly for raising a loan of five or six millions of money to be expended upon the roads, enormous benefits would follow to the country in the course of a few years. His Lordship also paid a warm tribute to the organising abilities of Mr. Smith, the hon. secretary of the Western Section.

Sheriff Fyfe gave "Automobilism," and remarked that the scientific aspects of the question were being more and more regarded by those in authority ; and their desire was that every opportunity should be given to develop the industry. The toast was acknowledged by Count Louis de Clercq, representing the Automobile Club de France ; and by Mr. Julian W. Orde, representing the Automobile Club of Great Britain and Ireland.

The other toasts were "The Corporation of Glasgow," by Mr. N. P. Brown, acknowledged by Bailie M'Innes Shaw ; "Our Guests," by Mr. John Adam, acknowledged by Councillor Gray ; and "The Chairman," by Mr. Henry M. Napier.

YORKSHIRE.

A GENERAL MEETING of the members of the Yorkshire Automobile Club has been held to consider the question of affiliation with the A.C.G.B.I. and the Motor Union. Mr. E. H. Hepper, vice-president took the chair at the meeting, but there was only a small attendance. Mr. W. Rees Jeffreys, secretary of the Motor Union, attended the meeting. The opinion of those present appeared to be principally in favour of continuing the existing scheme of affiliation. On the other hand, it was contended that the money which might be saved upon the affiliation could be usefully applied to other branches of the club's work. As an example it was pointed out that the club in the future would have to face some expenditure on paid secretarial work. At

Digitized by Google

previous meetings the affiliation scheme has come in for a good deal of criticism, the Huddersfield branch in particular having complained of the cost. After a long discussion, on the motion of Mr. H. A. Jones (Bradford), seconded by Mr. R. Winn (Leeds), it was unanimously decided to continue the affiliation on the 10s. 6d. basis.

MAGISTRATES TO DEFEND THEIR VERDICT.

Mr. Abner Hassall had been driven through Danbury, in Essex, and subsequently received a letter demanding information to lead to the identification or conviction of the driver on the day in question.

The police had not warned anybody on the car at the time, or signalled them to stop, but they took the number of the car and applied for the name of the driver of the registered owner, some time after.

The alleged offence was for travelling over twenty miles an hour under section 9 of the Act, and although Section 1 makes it obligatory upon the registered owner to give information respecting the driver in cases of reckless driving, and only then where the driver refuses to give his name and address, or gives a false one, yet Mr. Hassall was convicted and fined by the Chelmsford magistrates. Mr. Horace Avory, K.C., with him Mr. White (instructed by Messrs. Firth and Company), have applied to the Lord Chief Justice and Mr. Justice Ridley for a writ of certiorari to issue against the magistrates to justify their action, and an order has been made upon the magistrates to show cause why their decision should not be quashed. The magistrates who tried the case were Sir F. Carne Rasch, Bart., M.P., and Mr. Fred Chancellor.

CASE DISMISSED.

On Wednesday of last week, Mr. R. V. Asbury, of Paddington, was summoned before the Croydon magistrates on the charge of refusing, when driving a motor-car, to cause the motor-car to stop and remain stationary as long as was reasonably necessary, at the request of a constable in uniform. Mr. R. Pike, Glasgow, instructed by Messrs. Kenneth, Brown and Co., defended. The police gave evidence to the effect that Mr. Asbury's car ran over a dog and that the police-constable then stepped from the kerb into the roadway and signalled to Mr. Asbury to stop, which he did not do. After hearing the case, the Bench declined to convict and dismissed the summons.

MOTOR-CAR v. COACH.

A collision between a stage-coach and a motor-car has been the subject of an action at Llandudno County Court. Mr. Davidson, assistant water engineer to the Liverpool Corporation, was proceeding in his automobile past Llandudno Junction in July last when he overtook a four-in-hand. A collision occurred, and the car sustained damage, for which its owner now claimed compensation on the ground that the coach driver was negligent in turning, as he was alleged to do, without warning other users of the highway in his rear. A verdict was given for the plaintiff. Damages, £14.

A MOTORIST SENT TO PRISON.

The trial has taken place at the Shire Hall, Warwick, before Mr. Justice Bucknill, of Thomas S. Stevens (21), Coventry, on the charge of the manslaughter of John Hales, of Whitefriars Street, Coventry, at Kenilworth, on August 31st. Mr. H. A. McCardie and Mr. H. H. Joy prosecuted, and the accused was represented by Mr. Hugo Young, K.C., Mr. J. J. Parfitt, and Mr. Maddocks. The circumstances of the case have already been reported, and after hearing evidence the jury returned a verdict of guilty. The judge said the verdict meant that the jury had satisfied themselves beyond a doubt that his driving was reckless, and criminally reckless. He must respect that verdict—he bowed to it, as prisoner had to. It was sufficient for him to say that he was satisfied it was an honest verdict. He then sentenced the motorist to a month's imprisonment in the second division.

DANGERS OF THE ROADWAY.

At the Cardiff County Court the case of the Cardiff Motor Garage, Limited, v. the Cardiff Corporation has been concluded. Mr. A. J. David explained that the action was for damage to a motor-car, sustained through defendants leaving a cut-up portion of Ely Road insufficiently protected. The contention of the plaintiffs was that there were not sufficient lights properly placed to warn people. In summing up, his Honour commented upon the fact that the nearest lamp to the free portion of the road was 7 feet from the kerb, and not at the end of the pole. The jury awarded plaintiffs £35, expressing the opinion that the Corporation did not use sufficient lights. Judgment was given in accordance with the finding of the jury.

LADS ON VEHICLES.

At the West London Police Court Messrs. Pickford and Company were summoned for infringing the Motor-Car Act by allowing to be driven a light locomotive, to which was attached a laden van on which there was no person competent to apply the brake. P.C. Pearman, 37 F R., said he saw one of the defendant company's vans in Bayswater Road. It was drawn by a motor-car, and there were two persons on the car—a man and a boy aged 15. There were brakes on both the car and the van attached, but the witness contended that the boy of fifteen was not competent to apply the brake on the van. The boy, he explained, was engaged in cleaning and oiling the car, but his usual place was on the van, where he was stationed for the purpose of applying the brake.

The case had been brought in order to test the question whether a boy of fifteen was competent to apply a brake. The magistrate remarked that that depended on the boy, who was called. In reply to the magistrate the boy said he was quite able to apply the van brake—even half-way down a steep hill. Mr. Pierron said the case was of great importance, not only to carriers like Pickford and Company, but to all who employed motor-cars in their carrying business, and he submitted there was no evidence to show that the boy was incompetent to apply the brake. The magistrate agreed and dismissed the summons.

Mr. W. Pilkington, a director of the Rex Motor Manufacturing Co., Ltd., gave a dinner at the King's Head Hotel, Coventry, last week, to the staff and employees, numbering about 250, of his firm in celebration of the coming of age of his son, Mr. W. Pilkington, jun. After the removal of the cloth a concert was held, at which Mr. Arthur Pilkington presided, Mr. G. Pilkington occupying the vice-chair. The latter had the pleasant duty of presenting Mr. W. Pilkington, jun. with a handsome gold watch and chain, subscribed for by the workmen.

In our old friend "Notes and Queries" a correspondent has been asking whether there is any clue to the system on which the distinguishing motor-car signs have been awarded. London rightly leads off with a solitary A, and I and S seem to be sacred to places in Ireland and Scotland respectively; "but why," he asks, "should Glasgow be the only town or district that has any dealing with G? Why should Devonshire be D; Leeds, U; Northumberland, X; Somersetshire, Y; the North Riding of Yorkshire, A J; the East Riding, B T; the West Riding, C; and York itself, D N? 'That way madness lies.' I have studied Throup's waistcoat-pocket book of 'Motor Index Marks' to but little purpose, and never before found the alphabet so difficult to deal with. Can anybody make easy the hornbook of my second childhood?" The answer is simple. There is no clue—or reason for the system, or rather, lack of system, displayed in the assignment of index letters.

In view of the advance of automobilism in Australia, new regulations with regard to the speed of motor vehicles in Victoria have been suggested, and legislation on the subject is shortly to be introduced. According to advices we have received this would seem to be somewhat on the lines of the English Motor Car Act. Cars, it is suggested, should be numbered and drivers licensed. The distinctive difference between the proposed Australian law and that in operation in this country is concerned with the speed limit. This is to be restricted to ten miles in towns, and allowed to go up to twenty-five miles an hour in the open country. Doubtless in suggesting this wider range regard has been paid to the conditions of the Colonies with regard to populations in the rural districts. The idea of a speed limit seems to appeal to the non-motoring community in these early stages of the industry. As experience grows the desire for such a limit will probably become lessened.

TO CORRESPONDENTS.

All communications intended for insertion in this Journal or relating to Editorial matters should be addressed to The Editorial Department, Motor-Car Journal, *39 and 40, Shoe Lane, London, E.C., and must be written on one side of the paper only. Letters must in all cases be accompanied by the name and address of the writer, as no notice will be taken of anonymous communications.*

The Editors cannot undertake to return MSS. or drawings, although every effort will be made to do so in the case of rejected communications. Where such are regarded as of value, correspondents are requested to retain copies.

To insure insertion communications and contributions must be in the Editor's hands by Tuesday forenoon of the week in which the same are intended to appear. Disappointment may be caused by non-compliance with this rule, and to avoid this earlier receipt, if possible, is necessary.

The Editors do not hold themselves responsible for the opinions expressed by their correspondents, or for statements and facts which do not appear in the editorial columns.

The Editors and Publishers beg also to state that they will accept no responsibility for unsolicited contributions, even if used, unless payment for same is directly specified in forwarding, and the terms arranged before publication.

THE

Motor-Car Journal.

VOL. VI.] LONDON, SATURDAY, DECEMBER 24, 1904. [No. 303.

Published Weekly by CORDINGLEY & CO., 39 & 40, Shoe Lane, London, E.C.

COMMENTS.

SEASONABLE greetings should introduce the *Journal* this week, and we take the opportunity once again of wishing all our readers a Christmastide full of happiness, and a New Year bubbling with prosperity and cheerfulness. Trade has been slower than the automobile during recent months, but most people are looking to 1905 with optimistic vision. We trust their faith in the future will not be misplaced, and hope that the present Christmas season may prove an augury of bright days and pleasant avenues for the motorist—both the maker and user of the car.

◆ ◆ ◆

The Renewal of Licences.

IN reply to various correspondents who have written with regard to the renewal of licences, we would remind all whose permits are about to expire that they should be renewed by the County or County Borough authority in the place where the applicant resides. Those who have removed since the first issue of the licence should take out a new licence with the authorities in the County or County Borough in which they are now living. Several readers have imagined that renewal must be with the office from which the licence was originally issued. Section 3 of the Act is explicit on the point as follows:—"The Council of a County or County Borough shall grant a licence to drive a motor-car to any person applying for it *who resides in that county or county borough*, on payment of a fee of five shillings, unless the applicant is disqualified under the provisions of this Act." The same provisions apply with respect to the renewal of the licence as apply with regard to the granting of the licence.

◆ ◆ ◆

Hand and Foot Control.

THE correspondence following Mr. Percy Richardson's article on this subject proves the interest that is taken in the matter. Already many well-known designers and constructors have given us their views, and amateurs and others are invited to send their opinions for publication. When the correspondence has run its course Mr. Richardson will reply to the various criticisms of his conclusions—a fact which should encourage our readers to make their particular notions known, with a view to helping the solution of one of the many interesting problems associated with the development of automobilism.

◆ ◆ ◆

Professor Hele-Shaw.

ON Tuesday evening a farewell dinner was given by the members of the Liverpool Self-propelled Traffic Association to Professor H. S. Hele-Shaw, prior to his departure for South Africa. Mr. T. Thornycroft Vernon presided, and, in proposing the health of the guest, expressed the hope that his work in South Africa would be attended with the same success as had marked his labours in Liverpool. In regard to automobilism Professor Hele-Shaw's services had been of the utmost importance and utility, and the members of the association had always found him ready and willing to assist them in advancing the interests of the movement. Mr. Lyle Rathbone supported the toast, to which Mr. Burton, Mr. Blair, and Mr. Duncanson also spoke. In responding the Professor paid a tribute to the work of his colleagues at the Liverpool University. With regard to automobilism, he mentioned the excellent services rendered by Liverpool on behalf of this movement, and trusted that the association would continue to further the objects which it had in view.

◆ ◆ ◆

South Wales Automobile Club.

AT a meeting of the South Wales and Monmouthshire Automobile Club at Cardiff, with the Rev. Miles Whiteside in the chair, five new members have been elected to the club, including the first lady member, Miss L. C. Humphrey, who is now touring across France. Although it was definitely decided to hold a hill-climbing contest and gymkhana, the event was left undated in order that it might fit in with an engagement of the Gloucestershire and Leicestershire Automobile Clubs. The efforts of the club to improve the conditions of the road leading to the West Wharf, Cardiff, are apparently having effect, the Health Committee of the Cardiff Corporation having moved in the matter. The Secretary presented a statement showing the financial position of the club, which is thoroughly satisfactory.

◆ ◆ ◆

Motor-Car Imports and Exports.

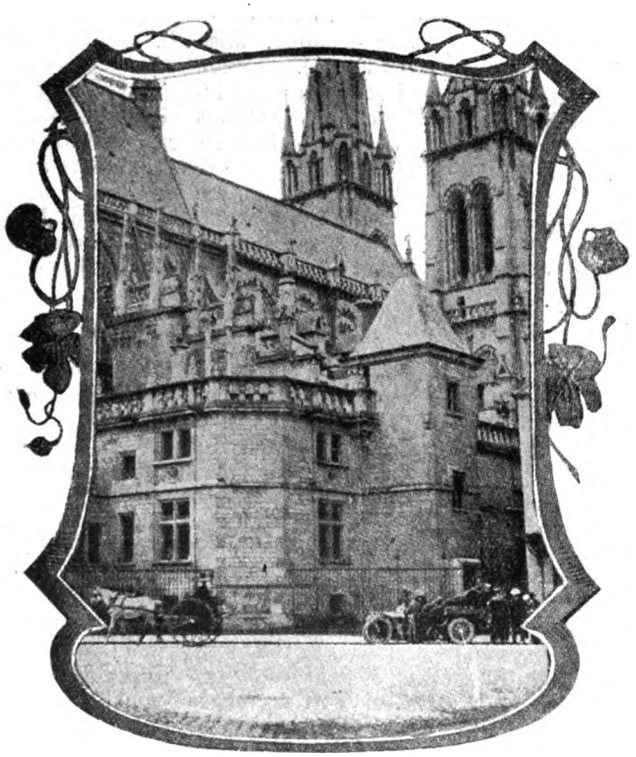
ALTHOUGH there was again a falling off in the number of foreign motor-cars imported to this country during the past month, there was, on the other hand, a slight increase in the value of the imports. The number of cars imported in November is returned at 237, of a value of £99,518. Parts were responsible for £28,871, bringing up the total for last month to £128,389, as against £123,980 in November, 1903. So far this year, that is to say for the first eleven months, the imports stand at £2,305,367, or approximately £404,000 more than in the same period of last year. Passing now to the exports of British automobile productions, the returns show a satisfactory improvement, altogether 96 vehicles being shipped last month, which, with the "parts," attained a value of £40,037, while for the eleven months ending with November the exports are returned at £280,084.

◆ ◆ ◆

In the Lake Country.

THE suggestion for a motor-boat race on Lake Windermere seems to have aroused the concern of the local Izaak Waltons who are in the habit of angling in the waters around Ulverston. Mr. Fell, at the first meeting of the newly elected Fishery Conservators' Board for the rivers in that district, has been commenting upon the suggestion, and said he was not at all sure that such an innovation would be welcome news to anglers of the Lakes. The conservators would have to consider whether the constant movement along the shores of the lake would be beneficial or detrimental to angling, and latest reports from the locality seem to show that the members of the Lake

Digitized by Google



District Angling Association are now giving the matter their attention. It would be rather interesting if the pioneers of the motor-boat movement found anglers as prejudiced against their movement as are agriculturists to the development of the road car. But the incident affords some evidence of the many different angles at which the automobile movement touches the social life and habits of the time.

An Anti-Speed League.

SUSSEX, which has had as much experience of police traps as any county in England, has at last produced a hero who comes forward with a proposal for an association to regulate the speed of motor-cars. Mr. J. H. Nunn is apparently willing to support his sentiments with financial aid, and suggests the formation of a league "to create such a body of public opinion as would influence the members of the House of Commons, who will be glad to appoint an early date to discuss the next Motor Car Act." He will be most happy to subscribe £100 to such a society, and suggests that subscriptions of 6d. and 1s. should also be welcome, so that the organisation may embrace all sorts and conditions of men. Mr. Nunn's address is Lealands, Hellingley, Sussex, which we give here for the benefit of those motorists who may be willing to help his automobile education by taking him for a trip on a fairly fast car along some of the roads of his favourite county.

Motor Touring in France—at the Cathedral of Bourges.

◆ ◆ ◆

After Dust—Mud.

THE Middlesex County Council has received £1,809 in fees for licences and registrations in connection with the Motor Car Act, and at its last meeting resolved to expend £2,250 in erecting notices at dangerous corners and similar positions, warning drivers of motor-cars as to the risks they run in going too speedily along such routes. Although this sum is rather in excess of the amount received from automobilists, it is considerably less than was desired by the local authorities which requested the Middlesex County Council to do the work. It is satisfactory, however, as an example of the right spirit, which we hope will be followed by the councils throughout the country. When motorists have been universally warned of awkward corners on the road, the time will come for the authorities to see to the roads with a view to preventing the troubles that have been caused by allowing the highways in many places to get into a bad and broken condition. Then, too, they will have to consider the actual construction of the roads themselves; otherwise gentlemen like Mr. Cockburn, the chairman of the Kingston Bench, will be again complaining of the mud that is thrown up by motor-cars when passing through the streets of this well known town. It appears that on the day of Sandown Park races he saw an automobile driven along the Portsmouth road which was apparently in a particularly muddy condition, with the result that ladies standing on the pavement were "smothered in mud; in fact, had a regular bath of mud." This is a luxury hardly appreciated in the present state of civilisation, and must be put down as a result of the neglect of the local authorities to keep the streets properly cleaned. Otherwise the ordinary respectable motor-car passing along would never have rendered itself so offensive to people who were merely standing on the pavement. The neglect of local authorities in the past has had much to do with the dust nuisance, and it is to be hoped that they will not also give countenance to what is undoubtedly an inconvenience in wet weather, namely, mud splashing from fast-going vehicles.

◆ ◆ ◆

The Locks on the Thames.

THE news published last week with regard to the freeing of the locks on the French rivers to motor-boats affords a striking comparison with the state of things on the Thames, where the new sport will be seriously handicapped by the many locks and the high charges for such craft. As a matter of fact the lock rates for a small motor-boat are as high as those for a steamer carrying a hundred passengers. Surely some distinction may be made in the near future with a view to enabling the motor-boat to become a popular feature of the river traffic. To class it in the same category as the Thames steamers is, on the face of it, absurd.

◆ ◆ ◆

Sense in Suffolk.

SOME of the county councils are wiser than the smaller parish and district bodies, which spend much time in the discussion of problems the purport of which they see but darkly. Thus the Woodbridge Urban District Council has been passing a resolution calling upon the county authority to impose a restricted speed limit on motorists passing that way. The matter has been well discussed by the East Suffolk County Council, of which Lord Rendlesham is chairman, where, by thirty votes to nine, the application was declined. We congratulate both bodies on this decision, for the matter is too important to be regarded in any parochial spirit. There is need to look at this question of restriction from the national standpoint. Closing a road to motorists, or harassing them in any way, may appear a small thing in the locality, but if it hinders the progress of visitors to places beyond, it becomes a matter of hurt to a district. Hence the need for regarding all such suggestions with the most impartial mind.

◆ ◆ ◆

Roads—A National Issue.

THE national aspect of the question must never be overlooked. Great main roads should be under one control from end to end, and both construction and repair should be carried out on a thoroughly systematic plan. Now that country runs of a few score miles a day are an ordinary feature of travel, there is a need for long stretches of roads through several counties with an uniformity of surface that cannot always be secured by the present idea of county authorities. This is an aspect that should be kept well to the fore by all automobilists.

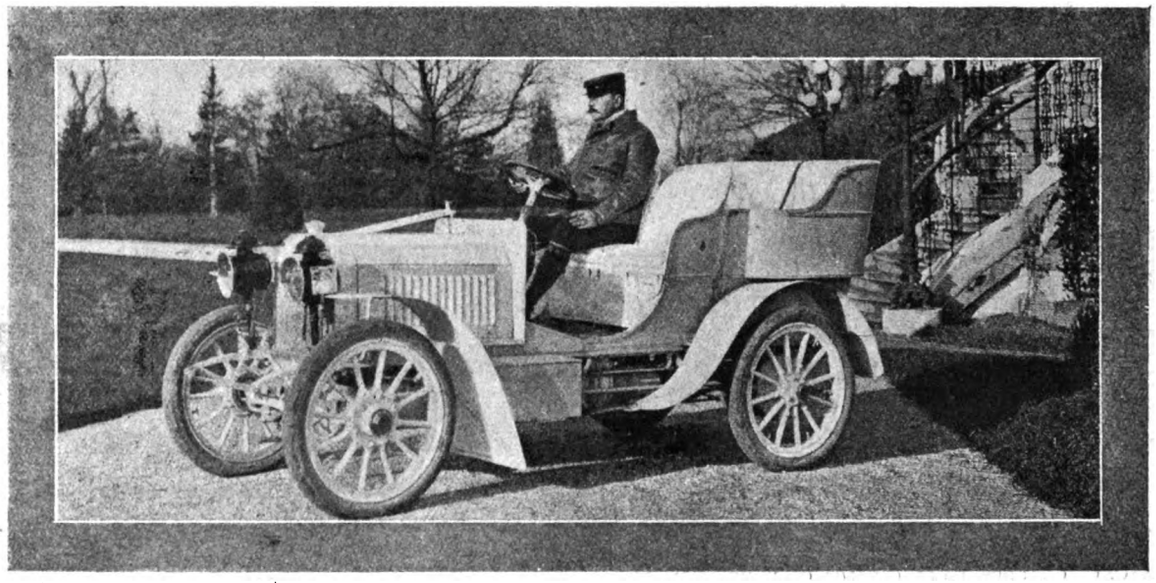
The Choice of a Car.

A POINT that is of the first importance in a petrol car, says Mr. Filson Young in the new book reviewed recently, is that all parts liable to wear and to need re-adjustment should be easily accessible without the unscrewing of numberless bolts and the unbuilding of half the car. Such things as inlet and exhaust valves, commutators, water-pumps, clutch springs, and gear cases should all be easily exposed and got at for the purpose of examination and repair. Lubrication should be positive and efficient, and the oil should be conveyed through pipes of decently large diameter. Steering gear should be strong and simple, with some provision for the taking up of wear. The breaking of steering gear while a car is travelling may not improbably have fatal results, while nothing is more unpleasant than loose steering connections which allow of much back-lash in the wheel. All nuts should be of what is known as the "castellated" type, and secured by split pins. The engine and its gearing should be protected underneath by a screen from dust and mud; in fact, the more the moving parts of a car are dust-proof and oil-retaining the better it will run. Oil and grease cups of a liberal size should feed all bearings which are not automatically lubricated, and the wiring of the ignition system should be as simple and as well insulated as possible.

◆ ◆ ◆

A Vicar's Views.

THE Rev. F. T. Wethered, vicar of Hurley, near Marlow, is a determined anti-motorist, whose antipathy breaks out in letters to the local journals and other ways. Fortunately, the prejudice is so thinly veiled that we do not anticipate any ill-effects from the reverend gentleman's declamations, anathemas, and other denunciatory attacks upon the car that moves without the help of horses, bullocks, or other troublesome animals. Mr. Wethered's latest contribution consists of an extract from a volume in which appears an account of the stoppage of a road steam carriage outside the shop of the local blacksmith at Hurley. The tale is seventy-two years old, and we are now told that "the dreadful motor-cars" that frightened the villagers three-quarters of a century ago have made the roads "simply impossible for carriages." If that is so, the carriages must get out of the way, and, according to one of our legislators, such a change is likely to happen in a couple of decades. What will Mr. Wethered say then?



Unattended Horses.

AT Stonehaven Court a crofter who pleaded not guilty to leaving his horse and cart on the road at Portlethen without any person in charge has been fined £3, and he and his friends have doubtless been much surprised. It appears that Dr. Cruickshank and Mr. A. L. Wood were driving to Aberdeen in the doctor's motor-car, and encountered the horse and cart. In endeavouring to clear it the motor wheel skidded, and the occupants were thrown out. Not only in Scotland is the habit of leaving carts unattended practised to the danger of motorists and other users of the road. Such salutary lessons universally administered for a month would rid the roads of many chances of accident.

A Reverend Advocate.

AMID all the attacks that have been made on motorists and their vehicles at various meetings of Chambers of Agriculture held during the last week, the speech of the Rev. P. E. Mainwaring stands out in pleasant relief. A resolution in favour of more stringent regulations than now prevail had been moved at the meeting of the Stafford Chamber of Agriculture, when the reverend gentleman, without objecting to the terms of the resolution, said he should like to say a word on behalf of a method of locomotion which was both a pleasant and a very useful means of getting about the country. There was no doubt a certain amount of nuisance and danger arising from the motor-car traffic, but that resulted not from the use, but from the abuse, of motor-cars. He had himself been using a motor-car for eight months, and had never experienced any difficulty whatever. If he met a restive horse, he stopped his machine and did all that was necessary in the circumstances. We believe this is true of most motorists.

Prince Solms Braunfels, President of the Austrian Automobile Club. [*Automobil Welt.*

The Education of Horses.

SEVERAL times have we urged that automobilists should offer every facility for owners of horses to practically demonstrate to their animals that the automobile is a harmless and friendly machine, not at all the ferocious monster some of their drivers would have us believe it to be. We are glad to recognise the growing disposition on the part of owners of horses to bring their animals to a right understanding of the automobile, and the article on another page in the present

Digitized by Google

issue should do something to reassure them of the ease with which the motor education of the average horse can be begun.

◆ ◆ ◆

The Effect of the Car on Rural Populations.

MR. G. H. YOXALL, M.P., sends a useful plea for the extension of motor-car traffic as the result of the experience of France. There he has repeatedly noticed that the development of the automobile for ordinary rural transport has affected the well-being of the district very favourably. Not only have the roadside inns revived, but around them, in almost every village, have sprung up fresh occupations or calls for additional service in old occupations, such as those of the mechanic who repairs, the shopkeeper who supplies motor fuel, &c., the inn servants, and so forth; so that motor traffic along the high roads really means more and more varied occupation for village dwellers than would otherwise be the case. In France, too, the motor is also promoting an emigration of town dwellers to live in villages, because of the greater pleasantness of the surroundings, the motor between town and village obviating the drawback, which

The Residential Radius.

BUT while the character of the estate agents' business has changed, it must not be supposed that only loss has to be recorded. True some districts have declined owing to the growing traffic of all kinds that makes a ceaseless clatter unsuited to quiet people; but, on the other hand, the residential radius has been greatly extended. Distances have been swallowed by the motor-car, and the small towns twenty miles from London have been able to attract residents who would have remained in town but for the facilities for rapid travel, independent of the railway, provided by the automobile. That is an elementary fact to be realised in the initial stages of any discussion on the matter.

◆ ◆ ◆

The Trials in India.

INTEREST in the forthcoming Delhi-Bombay motor trials continues to increase, and cups for various merits are being offered by the Gaikwar of Baroda, and the Maharajahs of Gwalior, Mysore and Kapurthala, as well as by some of the leading commercial firms in the Dependency. All the

previously existed, of distance from centres of population and places of business. This aspect of the matter should cause the most ardent anti-motorist to reflect upon the errors of his views.

◆ ◆ ◆

Changes in Cities.

THAT changes in the social habits of the people will follow the general adoption of the automobile is inevitable, and the first class of people to realise the altered fashions of the time are those estate agents of the West End of London who have large connections among riparian folks. At the annual dinner of their Institute, a few evenings ago, the Hon. W. H. Goschen referred to the conditions affecting house property in London as altering from day to day. The present demand was for excitement, and that took the form, amongst other things, of running up to London on all possible occasions. Years ago people came up to town on January 1st, and remained until the end of the Parliamentary session. Then they disappeared until next year came round. But now people frequently came hopping up to London, and went to hotels instead of taking houses. An even more insidious enemy of house property was the motor-car, which had altered the face of West End life. The great West End shopkeepers would tell them that there were only three days a week for business now, because the smart thing was not to have a house in London, but to live just outside. People so situated could always get up to town for their amusements in the swift motor-car.

railway companies running into Bombay are giving special facilities for sightseers, and it is evident that the contest will arouse the interest of India in the automobile in a way it has never been excited before. Thirty-eight entries have been received, among them being the Maharajah Scindia, 12-h.p. De Dion; the Rajah of Pudukotah, 20-h.p. Gardner-Serpollet; Prince Ranjitsinhji, 12-h.p. Lanchester; Count Giulio di Gropello, 16-h.p. Fiat; Mr. A. Turckheim, 16-h.p. De Dietrich; Mr. S. F. Edge, 20-h.p. Napier; Mr. Arthur Hoare, 12-h.p. Clement; Mr. W. S. Sorel, 24-h.p. De Dietrich. There are also a Humberette, 6-h.p. Speedwell, two 6-h.p. Wolseleys, 10-h.p. Argyll, 12-h.p. New Orleans, and a 20-h.p. Thornycroft. We shall be glad to hear from our readers in India as to the effects that the trials have on the demand for cars.

THE EDUCATION OF THE EQUINE.

EDUCATIONAL matters have occasioned much controversy of late. That progress is being made in this direction, so far as the horse is concerned, is evident from the fact that no reference was made in the House of Commons discussion on the Motor Cars Act to the intractability of the horse in the presence of the motor-car. A few years of familiarity have effected wonders, and not only does the average horse regard the

The Lesson in the Stable Yard.

modern automobile with little feeling of alarm, but he is often less nervous than his driver.

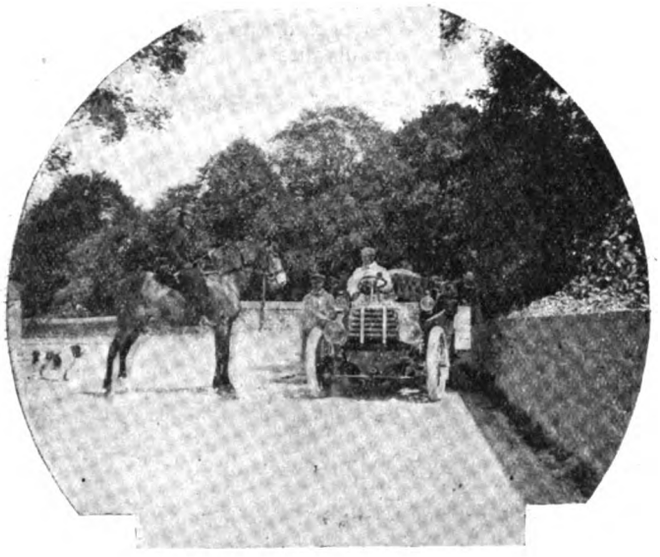
Often have we noticed that drivers of horse drawn traps have a startled look as the motor-car whizzes by, and frequently do they seem relieved when the mechanical carriage has passed on. The horse continues his journey as unconcerned as though he were meeting a member of the same tribe, and has evidently become well accustomed to the new locomotion on the highway. It is, however, a matter of common occurrence that when a horse appears to be going steadily towards a car coming in the opposite direction, the driver suddenly tugs at the reins, raises his whip, and otherwise unsettles the nerves of the animal in such a way that he becomes alarmed and rears about in terrified fashion as the car comes nearer. Then he shies, and the newspapers appear with graphic accounts of "Motor Mishaps," "Horse Frightened by a Car," or some other equally erroneous title. The truth is that half the cases of horses being alarmed by the motor-car can be traced to the ineptitude of their drivers, or the foolishness of passengers in cart or car who herald the approach of horse or motor with a series of noises intended to be reassuring words of welcome, but in reality notes of alarm to an animal with nerves overwrought by silly handling on the part of the driver.

The best way to deal with horses is for strangers to ignore their presence and their drivers to show some confidence in their own good sense, merely holding a firm rein and being prepared for all contingencies; but not violently intimating to their animals that something unusual is in the locality.

During a recent tour in Ireland the behaviour of the drivers of horses and donkeys in the south was in marked distinction to the indifference with which those about Dublin regarded the automobile. Around St. Stephen's Green, in College Green, and near Nelson's Pillar, were ranks for outside cars, the jarveys allowing their horses to stand still in the presence of scores of cars, and not a wayward animal was reported throughout the city. Several drivers told us that horses that could not stand still in front of tram-cars or motor-cars were of no use to them, and it was evident that the jarveys had carefully accustomed their horses to the cars. Down south, however, there was an obvious nervousness on the part of the people driving carts that was really needless. Without any warning they simply dropped from their seats, rushed to the heads of their horses, and frequently pulled them into the hedge until the cars had passed. That, however, was not the only result of such precipitate action. The whole length of the vehicle was projected across the road, and the passing automobile had little room in which to manœuvre between the hedge and the projecting pieces of the cart, for those primitive Irish vehicles are strangely lengthy in the rear.

One advantage of the official tours that have been held through various parts of the United Kingdom and Ireland since 1896 has been the education of horses that has taken place. The Reliability Trials starting from the county town of Hereford accustomed the horses of that locality to the automobile, and not a few horse owners followed the example of the head of the local fire brigade, who paraded all his horses before the cars, both stationary and when in motion. Two notable instances of good work thus done by motorists occurred to us while going from Dublin to Cork with Mr. S. H. Pearce, on that gentleman's trusty Napier—a car that has journeyed over all sorts and conditions of roads in Northern Africa as well as in Southern Europe. We had been stranded one evening at Dungarvan—the reason of which is another story, to be told on a later occasion—and met a coastguard officer from Youghal. He had a spirited horse that did not care for motor-cars any more than the Rev. Mr. Spalding liked London. In fact, our coastguard friend almost regarded his quadruped as an unconvertible heathen so far as automobilism is concerned. We assured him the horse was an intelligent creature, and that a little coaxing and patience would give him a good rudimentary education. Though sceptical, he cheerfully accepted the offer of Mr. Pearce to become a tutor of the equine the following morning.

Breakfastless and wondering the horse was led into the hotel yard in the morning and paraded around the car. He acted like a bear on hot bricks, and when the engine was started gyrated in a fashion that would have scattered the most curious London



Horse and Motor-Car starting together from Dungarvan.

crowd. After a while the engine was stopped and a pailful of corn placed in front of the radiator. Gee-Gee looked askance, but his hunger was great and unusual, and with a somewhat questioning glance at his master he dipped his head into the pail, quickly to remove it. Three or four attempts gave him assurance, and he was soon busily feeding. Then the engine was re-started, and the old nervousness re-

Digitized by Google

turned for a moment. The appetising corn was unfinished, and the horse, risking the noise of the engine, continued his meal. He concluded his breakfast with the motor in full revolution, and then quietly walked around it as though, the introduction being over, he was prepared to be friendly. Patiently he stood as the car was driven out of the yard, and subsequently allowed himself to be driven by the side of the automobile to

On the Bridge at Lismore.

the front of the hotel, where the scene was photographed. Thus was the horse of the Youghal coastguard given a very necessary and interesting lesson.

Arriving at the bridge spanning the Blackwater, under the frowning turrets of Lismore Castle, we met a clergyman on as fine a quadruped as we had seen in all Ireland. Gallantly steering the noble creature towards the car, he had a tough contest for mastery. For a few minutes the issue was in the balance; but intelligent and patient handling did their work and the horse was made to stand quietly by. At the request of the clergyman some interesting manœuvring was performed with the horse and the car, and the last scene of all, ere each went his own way, is depicted in our third illustration.

There is no doubt that those owners of horse-drawn vehicles who familiarise their horses to the automobile are wise in their generation. The automobile is the inevitable vehicle of the road for the future. It will be seen in every form and for every purpose, conveying passengers from village to village, transporting produce from the field to the railway, and giving pleasure to tourists by enabling them to see the beauties of their own and other countries. Hence the necessity that lies upon owners of horses not to give way to the foibles and follies of their animals, but to persistently and consistently compel, using kindness as well as firmness in the operation, their animals to go forward whenever automobiles come their way.

MESSRS. MORS, LIMITED, has been registered with a capital of £15,000, to acquire English patents relating to motor-cars of the Société Anonyme d'Electricité et d'Automobiles Mors, to manufacture and sell in the United Kingdom and British colonies and dependencies, motor-boats and accessories in accordance with such patents, to deal in motor-cars and accessories made by the Compagnie Francaise des Voitures Electromobiles, and to carry on the business of garage proprietors, etc. The first directors are Messrs. S. L. Lazarus (chairman), L. Carle (managing director), D. Singer, G. de Wilde, L. Haarbleicher, F. Kerr, L. Auscher, M. Drummond, and C. Banbury. The registered office is at 55-59, Shaftesbury Avenue, W.C.

CONTINENTAL NOTES.

A Motor Boating Costume Competition.

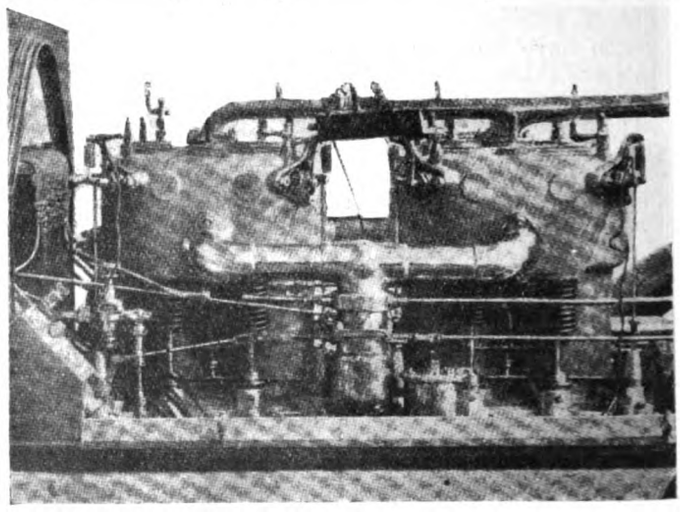
The "Auto," always full of new ideas in regard to competitions, now proposes to organise one as to the best costume for motor-boating. It is proposed to hold the same in connection with the exhibition at Monaco next spring, on the occasion of the motor-boat races in the south of France.

◆ ◆ ◆

Public Services in Germany.

Messrs. Bussing, of Brunswick, are building a number of motor-omnibuses for a public service between Harzburg and Braunlage. A company has also been formed to organise a service between Huy and Holberstadt.

◆ ◆ ◆



A New Liquid Fuel for Steam Cars.

M. Serpollet last week made another trial of the new liquid fuel for steam cars, referred to in the last issue of the *Journal*. The vehicle employed was a 20-h.p. 'bus, carrying eleven passengers, in addition to the driver. A distance of 102 kilometres (64 miles) was covered at an average speed of about eighteen miles per hour on a consumption of sixty litres of fuel. The cost of the latter was 7 fr. 20 cent., which works out at 6½d. per person carried for the whole distance. As already mentioned, the new fuel is derived from coal tar obtained from gas-works.

◆ ◆ ◆

The New 70-h.p. Mercedes Car.

Some further details are now available of the new 70-h.p. Mercedes car briefly referred to in the last issue of the *Journal*. The engine has its four cylinders cast in two pairs, a larger space than usual being left between the two pairs. The inlet valves are arranged on the opposite sides to the exhaust valves, all being mechanically actuated. The gear wheels driving the cam shafts are located at the front end of the engine; they are of bronze instead of the fibre hitherto used, and are entirely enclosed. The valves are of larger diameter than formerly, but have a reduced lift; the maximum speed of the motor has been increased from 1,100 to 1,400 revolutions per minute. The

The Engine of the new 70-h.p. Mercedes.

crank shaft now runs on special ball bearings, while an innovation is found in the pump lubrication, which only works when the engine is in operation. The carburettor is provided with a hot water jacket; the piston type of throttle has been abandoned in favour of discs which may be rotated so as to cause the slots in the same to more or less coincide and so vary the quantity of mixture allowed to pass to the engine, the air supply being automatically regulated at the same time. The throttle is now arranged not only to be operated by hand, but also by a pedal located between the clutch and brake pedals.

Motor-Cars in the Russian Postal Service.

As mentioned in a recent issue of the *Journal*, the Union Motor-fahrzeugfabrik Gesellschaft, of Nuremburg, Germany, has lately supplied a number of petrol motor-vans to the Russian postal authorities. The vehicles are of two sizes, both having the Union Co.'s system of friction drive; Fig. 1 shows the smaller type of van; it is of 6-h.p., and is designed to carry mails up to a load of

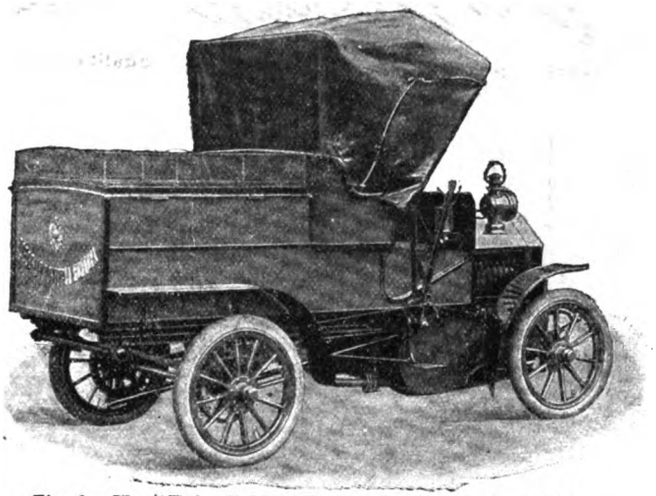

Fig. 1.—The "Union" 6-h.p. Van for the Russian Post Office.

6 cwt. at speeds up to twenty miles per hour. The larger vans (Fig. 2) are being used in the parcels post service; they are of 8-h.p. and are intended for loads from 11 to 12 cwt.

◆ ◆ ◆

The Michelin Cup.

At the meeting of the Committee of the French Automobile Club last week, M. A. Michelin referred to the growing tendency to fit *chassis* with increasingly heavy carriage bodies, and to the consequent difficulty of pneumatic tyre makers to produce reliable and durable tyres suitable for such vehicles. With the view of encouraging carriage builders to pay more attention to reducing the weight of bodies, he has offered a cup of the value of not less than £1,000 to the A.C.F., to be awarded annually to the carriage builder who shall produce the body which, while fulfilling all the usual requirements, shall be the lightest in weight. It is proposed to limit the competition for next year to a six-seated touring car, this being the type for which there is now a noteworthy demand. Unfortunately, M. Michelin has suggested that the competition be restricted to French carriage builders, but we trust that ere the definite rules are drawn up the A.C.F. will see its way to make the contest an international one.

◆ ◆ ◆

Motor-Cars in the Swiss Postal Service.

The 1905 Budget of the Swiss Post and Telegraphs Department provides for the acquisition of two additional motor-cars for use in connection with the postal service.

◆ ◆ ◆

The Monaco Motor-Boat Meeting.

No less than 75 entries have already been received for the motor-boat race meeting to be held at Monaco next spring. The English competitors include Mr. S. F. Edge, who has entered two boats, and Mr. Maudsley Brooke his "Baby" Brooke.

◆ ◆ ◆

Motor-Boat Racing on the Seine.

A series of motor-boat races was held on the Seine on Sunday last, the events being run off in beautiful weather and watched by thousands of interested spectators. The course was from the Alexander III. Bridge, near the Exhibition, to the Suresnes weir, the distance out and home being twenty-five kilometres. The racing craft had to make two circuits, equal to fifty kilometres, and the cruisers one round. Soon after daybreak the river began to assume unwonted activity, many of the competitors making trial spins to get their engines *au point*. The racing commenced at 11.30 a.m., the "extra reglementaires" cruisers with engines up to 8-h.p. being sent off first in batches of three, the winner being M. Frilet's "Satyre," with 8-h.p. De Dion engine, time 1 hour 45 min. 38 sec. The 8-12-h.p. cruiser class was won by M. Duplessis' "Etoile," with 12-h.p. Boyer motor, in 1 hour 29 min. 57 sec.; the 12-24-h.p. category by M. Cricq's "Mets-y-En," with 20-h.p. Chenard-Walcker engine, in 1 hour 10 min. 57 sec., and the over 24-h.p. class by M. Gaveau's "Marie Madeleine," with 35-h.p. Panhard motor, in 59 min. 8 sec. In the standard "cruiser" class for boats of less than 21 ft. in length, M. Claudel's "Titan IV.," with Delahaye paraffin engine, made the best time—1 hour 15 min. 18 sec.; the under 26 ft. cruiser category was won by "Titan III.," which is also fitted with a Delahaye engine, time 1 hour 13 min. 8 sec.; M. Perignon's "Dietrich III.," with De Dietrich motor, won the under 39 ft. class in 1 hour 1 min. 18 sec. Passing now to the racers, the under 26 ft. class proved a victory for M. Mestayer's "Titan II.," with Delahaye engine, the time for the 50 kilometres being 1 hour 58 min. 35 sec. The principal interest of the day was centred in the category for racing boats of a length under 39 ft. M. Henri Fournier was at the wheel of the "Hotchkiss" with 90-h.p. Hotchkiss engine, which was in fine trim. He covered the first circuit in 43 min. 24 sec., and completed the 50 kilometres in 1 hour 23 min. 33 sec. M. Legru's "Suzon-Hotchkiss," also with Hotchkiss motor, was second in 1 hour 42 min. 17 sec. M. Thubron's "Trefle-a-Quatre" (Richard-Brasier engine) third in 1 hour 44 min. 11 sec., and M. Kapferer's "N'a-pas-pied," with Napier engine, fourth in 1 hour 48 min. 13 sec. Some difficulty was experienced in getting the competitors to the starting point, and in some directions the management of the meeting left room for improvement. The event was, however, the first of its kind, and the experience gained will doubtless be taken advantage of in next year's meeting.

◆ ◆ ◆

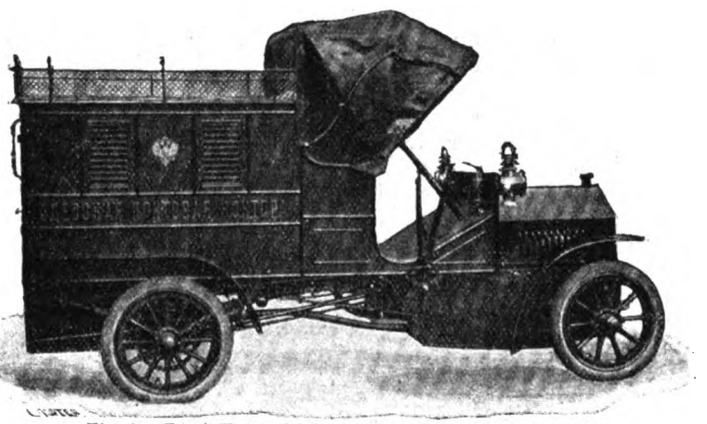

Fig. 2.—The "Union" 8-h.p. Van for the Russian Post Office.

The Paris Motor-Car Exhibition.

General View of the Salon.

THE *Salon*, which closes on the evening of Sunday next, has lost none of its interest, the Grand Palais being crowded daily by visitors from all parts of the world. On Thursday last week it was honoured by a visit from the King and Queen of Portugal, who spent some time in inspecting the leading stands. Below we continue our report of the leading exhibits.

Prominent on the stand of Messrs. BROUHOT & Co. is a 40-h.p. racer built for Lord Lonsdale, and a *chassis* of the latest type of 24-h.p. Brouhot car. This is fitted with an engine, the four cylinders of which are cast in two pairs. All the valves, both inlet and exhaust, are mechanically actuated off one cam shaft, and are consequently on one side of the engine. The ignition is by magneto, and the carburettor is of Messrs. Brouhot's own design and provides for the automatic regulation of the air in order to give the correct mixture at any or all speeds. A device

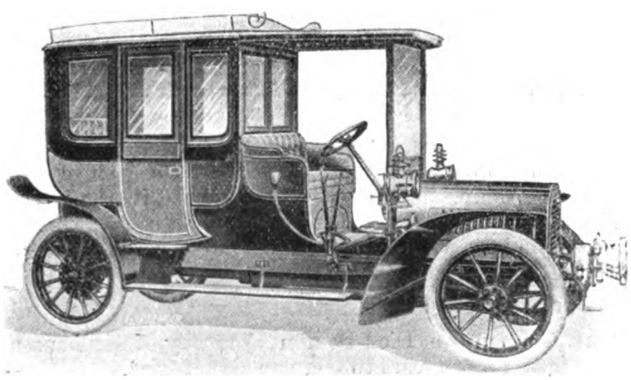

Fig. 23.—The Brouhot 24-h.p. Coupe-Limousine.

is also provided whereby the lift of the inlet valves may be varied and the speed of the engine consequently controlled. Pump circulation is adopted in conjunction with a honeycomb cooler, through which a current of air is drawn by a belt-driven fan. The transmission is by side chains, the drive on the top speed being direct. An ingenious form of friction clutch is employed to connect the engine with the gear box. The lubrication of the engine is ensured by a gear-driven oil pump. The road wheels are mounted on ball bearings, while the rear brakes are of the internal-expanding type. Two separate brake drums are provided on the countershaft. Among the detail improvements worthy of notice may be mentioned the chain-adjusting device and the steering bar which is now located behind the front axle. A *chassis* of the 15-18-h.p. type is also on view, as well as two or three complete vehicles, including the coupé-Limousine illustrated in Fig. 23. The Brouhot cars have made great progress during the past few years, and now rank among the high-grade productions of France.

For the 1905 season the LEON BOLLEE cars are being made in two sizes—20-24-h.p. and 40-45-h.p. An inspection of the

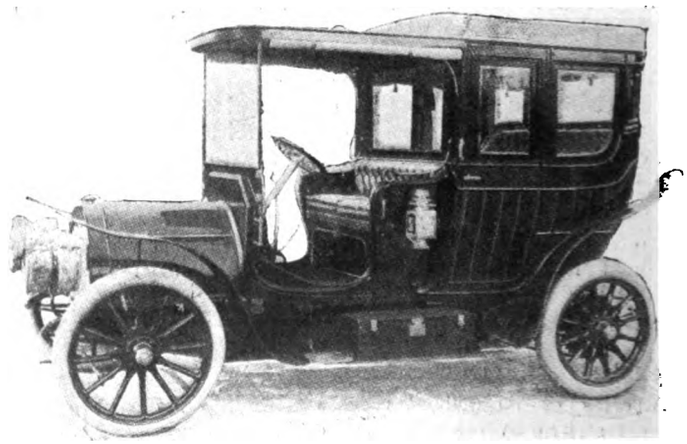

Fig. 24.—The Leon Bollee 20-24-h.p. Car.

40-h.p. *chassis* on view shows that while the general lines have been retained numerous modifications have been made. The engine comprises four cylinders, cast in two pairs. The inlet valves are mechanically actuated, and are located on the opposite side to the exhaust valve. The pump is of a new type; it is

Digitized by Google

driven by gearing from off the half-speed shaft, as is also the magneto. The fan fitted behind the honeycomb radiator is driven by a broad belt, the fan spindle being carried upon a rocking plate, sustained by an adjustable spring, so that the belt is always kept at the proper tension. The car is fitted with two distinct ignitions —magneto and coil, and the retarding or advancing of the spark of either is controlled by one lever from the steering-wheel. Coming now to the carburettor, this is on novel lines, consisting practically of two distinct spraying chambers. Up to a speed of about thirty miles per hour the mixture is supplied from the smaller jet. As the speed, and consequently the suction, of the engine increases the larger jet is brought automatically into action and the smaller one closed. The speed of the engine can be varied over a very wide range, and will run at as low a rate as 100 revolutions per minute. Passing to the clutch, this is also on special lines. The main portion is of the ordinary cone type, but the internal portion is mounted upon its shaft on a kind of spherical joint, so that it is capable of fitting accurately into the outer member, even if the shafts carrying the two members are not perfectly in line with one another. The clutch pedal is now so connected with the throttle that as the clutch is withdrawn the speed of the engine is automatically cut down. A flexible coupling is fitted between the clutch and the gear box. The latter, like the engine, is supported at three points. Four speeds forward and reverse are provided, these being arranged in such a way that it is possible to readily change from the first to the fourth. All the lubricators are named, and

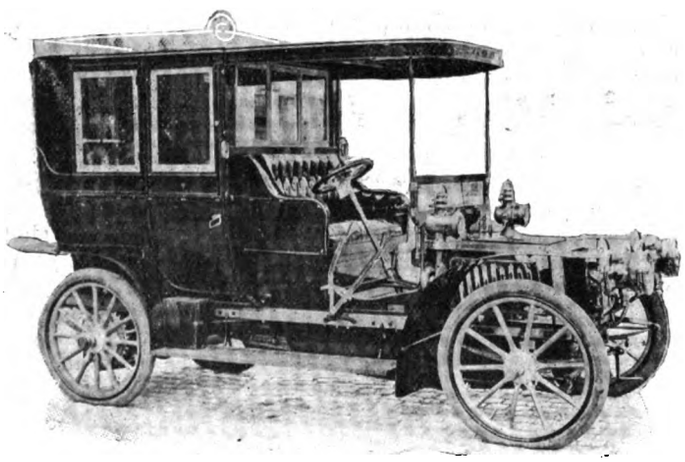

Fig. 25.—A "Pipe" Coupe-Limousine.

arrangements are made so that more oil can be fed to any desired bearing. The steering gear, differential shaft, and road wheels run on ball bearings. Some excellent specimens of side-entrance bodies are to be seen on the stand. We may add that the Victoria Carriage Works, of Long Acre, W.C., now hold the agency for the Leon Bollée cars in this country.

The COMPAGNIE BELGE DE CONSTRUCTION D'AUTOMOBILES, of Brussels, which is represented in England by the London Motor Garage Company, Limited, confine their exhibit to a *chassis* of the latest 18-22-h.p. Pipe car. The engine comprises four cylinders, cast in two pairs. The inlet and exhaust valves are all mechanically actuated off separate cam shafts. The valves are arranged in a somewhat unusual way—they open directly into the explosion chamber, not in a vertical line, as usual, but at an angle of 45°, the valve stems being actuated by rods and tappets. The ignition is by means of a gear-driven magneto; the radiator is of the framed rubber tube variety, the flywheel having its spokes arranged to act as a fan in drawing a current of air through the cooler. The clutch is of the metal-to-metal type; the gear-box, the shafts of which run on ball bearings, is arranged to give four speeds forward and a reverse. The Pipe cars have already an excellent reputation both in Belgium and England, which should be well maintained by the new models, which, in addition to the 18-22-h.p. above referred to, include 14-h.p. and 35-h.p. cars, both with four-cylinder engines.

Three splendidly-made *chassis* of respectively 18, 25, and 40-h.p. are to be seen at the stand of Messrs. CHARRON, GIRARDOT and VOIGT, who are represented in England by the

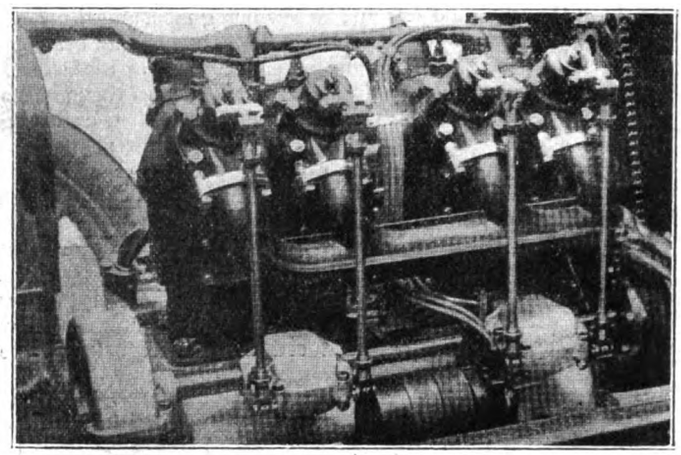

Fig. 26.—The new "Pipe" Motor.

London Motor Garage, Limited. The frame consists of a square steel tube filled with wood. The motor comprises four separate cylinders with mechanically-operated inlet valves. Both the pump and high-tension magneto are gear-driven. The carburettor is on the double-jet principle, with an automatic valve which closes the larger jet and opens the smaller when the engine is running at a low speed. The fly-wheel has its arms made in the form of a fan. The clutch is of an improved type, the aluminium male clutch member having a layer of rubber placed beneath the leather. A double cardan shaft is introduced on the shaft between the clutch and the gear-box. The

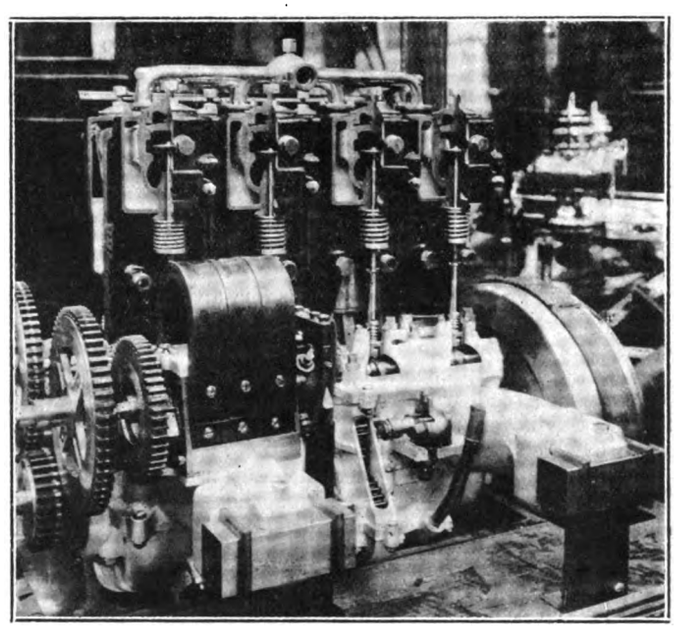

Fig. 27.—The C. G. V. Motor, cut in section to show operation of Valves

latter gives four speeds and reverse, with direct drive on the fourth; in it ball bearings are utilised. Altogether the C.G.V. cars are of the highest class, as an inspection of the various parts cut into sections displayed on the stand fully testifies. As regards the carriage bodies, these also are excellent specimens, and include a landaulet and a side-entrance Limousine.

Digitized by Google

The stand of the HOTCHKISS COMPANY is again attracting attention. Two models are shown of 17 and 30 nominal h.p. respectively, and although the general lines are the same as last year, a number of detail improvements have been introduced. The 17-h.p. engine has cylinders 112 mm. diam. and 120 mm. bore and is stated to develop 28-h.p. The larger engine has cylinders 125 mm. by 150 mm., and is estimated to give 42-h.p. The frame is of stamped steel; the engine comprises four vertical cylinders, cast in pairs, both the inlet and exhaust valves being mechanically actuated and interchangeable. The crank shaft runs on ball bearings, and although there were many who were sceptical as to the desirability of this, we are informed that no trouble whatever has been experienced. The ignition is by low tension magneto gear driven. The radiator is of the honeycomb type, of a circular shape; the tubes of the honeycomb are of a triangular section, giving a large radiating surface. The fan, inducing a current of air through the tubes, is made in such a way that the inclination of the blades or vanes can be varied from the driver's seat, and the air draught increased as desired, as, for instance, in mounting long hills. The clutch is on novel lines; it is of the leather-faced type, and is provided with a locking device which prevents any tendency to slip. A special joint is introduced in the shaft between the

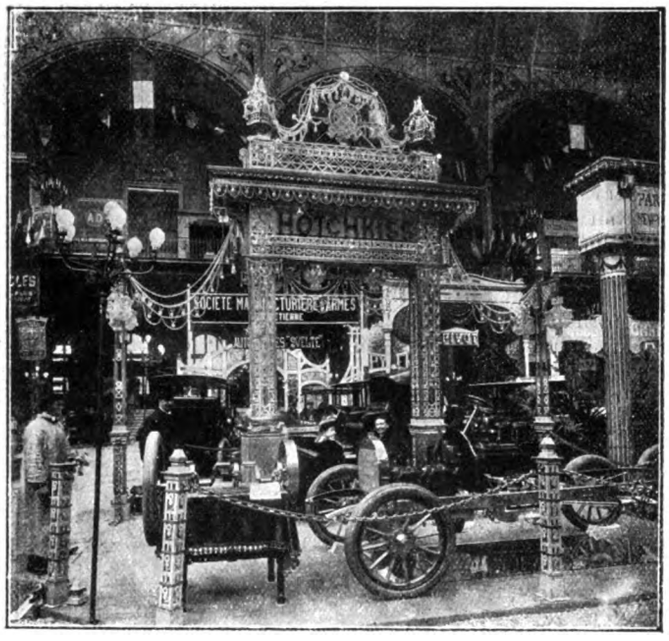

Fig. 28.—View of the Hotchkiss Stand.

clutch and the gear-box. Four speeds forward and a reverse are provided, the power on the top speed being transmitted direct to the rear live axle through a cardan shaft and bevel gearing. The rear axle is entirely enclosed and does not carry the weight of the car; the road wheels are mounted on the axle casing, and have the power transmitted to them through the axle ends; the case which encloses the differential and large bevel gear is divided in a horizontal, instead of, as usual, in a vertical plane. The bevel gear has been strengthened, a bearing being now provided behind the small bevel pinion. The pivots on which the front wheels are mounted lie in the centre of the hubs, and the steering rod is placed out of harm's way behind the forward axle. The brake on the countershaft is of the contracting band type, and those on the rear wheel hubs of the internal expanding variety, all being metal to metal. The frames are all of such a length as to receive side entrance bodies, several excellent examples of which are on view.

One of the most striking cars in the show is the Pope-Toledo Pullman, exhibited by an American concern—the POPE MOTOR CAR CO. The vehicle, of which an illustration is given in Fig. 29, is equipped with a four-cylinder engine of 50-h.p. The enclosed portion of the body has side entrances and seats five people, three facing forward and two backward. A folded table, which can be let down between the seats, is provided for writing or serving luncheon. The internal woodwork is natural mahogany, hand carved, while the upholstering is in pearl grey broadcloth. All the windows are arranged so that they can be lowered into the framework, rendering the car available for summer as well as winter use. The exhibit also includes examples of the Pope 20-h.p., 30-h.p., and 40-h.p. cars. All the vehicles have

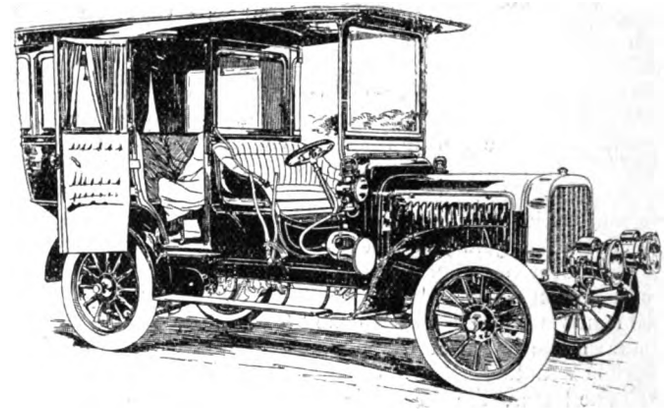

Fig. 29.—The Pope-Toledo 50-h.p. Saloon.

engines with four separate cylinders and copper water jackets. The inlet valves are of the suction type; the water circulation is maintained by a gear-driven pump and a special form of radiator, a current of air being drawn through the latter by the flywheel, whose arms are formed to act as a fan. Three speeds forward and a reverse are provided, the transmission being by side chains. The clutch is of the expanding segment type, while we noticed that the axles are of tubular construction.

LA SOCIETE L'ELECTRIQUE displays a number of its highly-finished "Gallia" electric carriages. Two electric motors are used, these being suspended at the rear in a special way, so that the body may rise and fall on uneven roads without affecting the motor. Accumulators of the "Supra" type are employed, these being arranged in two groups, one under the driver's seat and one at the rear. The forty-eight cell battery has a capacity of 220 ampere hours, sufficient to run the vehicle a distance of fifty to sixty-five miles at an average speed of twelve miles per

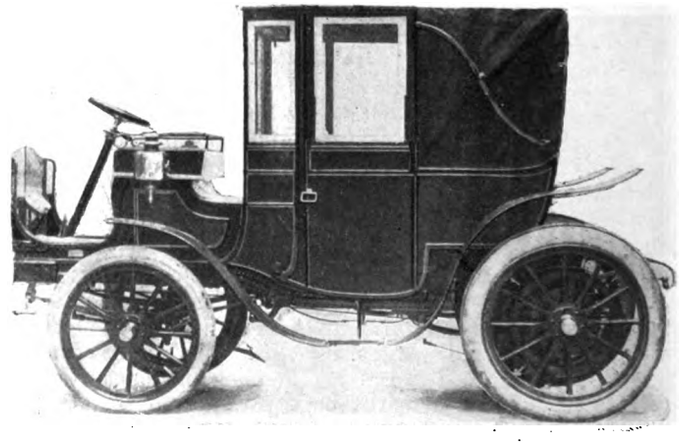

Fig. 30.—The "Gallia" Electric Landaulet.

hour. Steering is controlled by an inclined hand-wheel, and a special pedal is provided by means of which a resistance is inserted in the electrical circuit to permit of the car being started without jerk.

Messrs. BROWN BROS., LIMITED, have a large stand in the Gallery, on which they have an extensive display of all kinds of motor accessories.

Digitized by Google

At the stand of Messrs. DUCELLIER we met Mr. André Godin, the British agent, who pointed out to us the new models of the well-known Ducellier lamps, both of the acetylene and paraffin variety. One gas lamp has what is known as a "catadrioptic" lens, which gives a light of immense power. We notice, too, that in addition to brass and plated lamps, the firm are now turning out lamps with an oxidised finish, these being of attractive appearance. An extensible lamp bracket which will accommodate

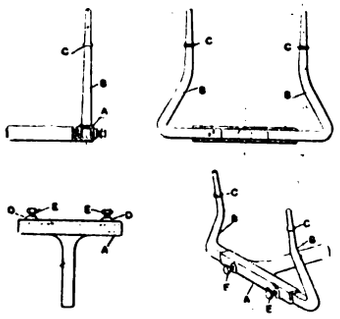

Fig. 31.—The Ducellier Extensible Lamp Bracket.

different sizes of lamps forms another interesting novelty at the stand of Messrs. Ducellier. Referring to the accompanying illustrations (Fig. 31), the T piece, A is that part of the apparatus which is secured permanently to the car in any suitable manner, the cross-head of the T being hollow and of square section. The lamp horns are made to slide into this square cross-head, one on either side, and can be moved in and out to accommodate not only the width between the sockets of any lamp to be carried, but within limits the position of the radial centre of such lamps can be varied. The adjustment between the centres of the horns CC varies from 5½ to 9½ in.

Quite a big display is made by the PEUGEOT COMPANY, the vehicles displayed ranging from the 6½-h.p. single-cylinder "Baby" to a 30-40-h.p. four-cylinder car. The 6½-h.p. car, which has been improved in many respects, has a frame of tubular construction. The engine, of which a sectional view is given in Fig. 32, is now provided with mechanically-operated

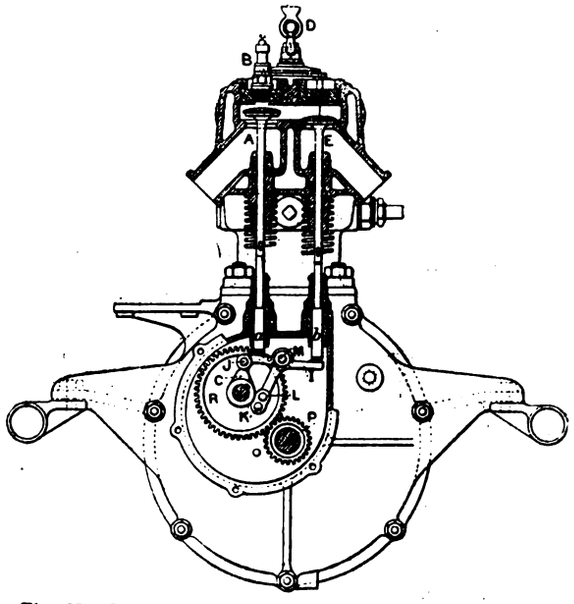

Fig. 32.—Section of Peugeot 6½-h.p. Single-cylinder Engine.

valves, a single cam actuating the inlet as well as the exhaust valve by means of the compound levers J, M, I, L. No governor is provided, but the clutch pedal is so connected up to the throttle valve that when the clutch is withdrawn the speed of the engine is automatically decreased. The water circulation is now maintained by a friction-driven pump in conjunction with a honeycomb radiator with fan. Three speeds forward and a reverse are provided, the top speed being direct on to the live axle. The two-cylinder Peugeot cars are only made in one power—12-h.p.—but in three lengths of *chassis*, the larger ones being intended to accommodate side-entrance bodies. Except that the frames are of wood and steel, the general details are similar to those of the Peugeot four-cylinder cars, to a reference to which we now pass. Three sizes of these are being made—12-16-h.p., 18-24-h.p., and 30-40-h.p., each being made with *chassis* of two different lengths—short for tonneau and long for side-entrance bodies. The frames are of pressed steel. The motors have the four cylinders cast in two pairs, and all the valves mechanically actuated, the inlets being on one side and the exhausts on the other. Magneto-ignition is fitted. The largest type has also the high-tension system by coil and accumulator as a reserve. One of the most novel features in the new four-cylinder cars is the automatic carburettor, an illustrated description of which was given in a recent issue of the *Journal*. The arrangement is most ingenious, the air admission being not only automatically regulated but also the feed of petrol through the spraying nozzle. To facilitate the starting of the engines a compression-easing lever is fitted close to the starting handle. The water circulation is maintained by a honeycomb radiator with adjustable belt-driven fan and gear-driven pump. With the view of rendering the vehicles free from jolting when travelling over rough roads, the Peugeot

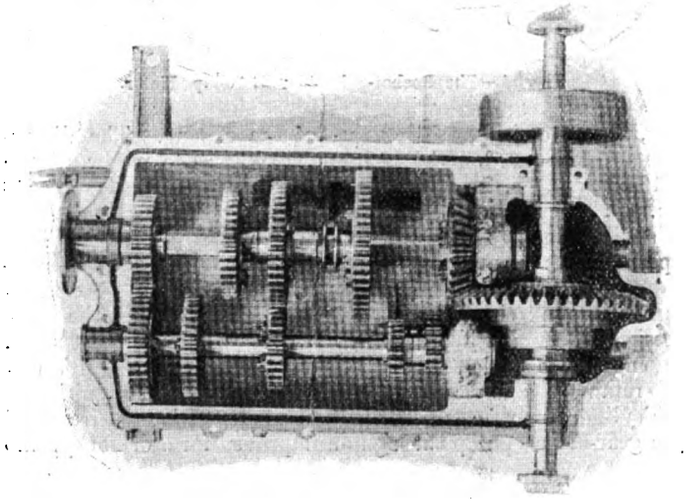

Fig. 33.—The Peugeot Change-speed Gear.

Company are still employing the cushioning arrangement devised by M. Truffault, which acts as a sort of brake on the springs, preventing them from rebounding on the frame. The change-speed gear box is adapted to give four speeds and a reverse, and a noteworthy feature is the provision of a groove extending right round the edge of the lower half of the gear box. Oil is fed to this groove and is conveyed to the bearings by means of chain-ring lubricators. The brakes are of the metal to metal expanding type. Attention may also be drawn to the fact that the magneto, which is gear driven, is so arranged that it may instantly be removed from its place whenever necessary. Altogether the Peugeot Company, whose destinies in England are controlled by Messrs. Friswell, Limited, has a display worthy of its reputation, and with such a wide range of cars, appealing to motorists of all classes, from the man of moderate means, upwards, there can be no doubt of these vehicles being as popular as ever in the coming season.

A new comer is LES CHANTIER DE LA BUIRE, of Lyons, which is showing two types of cars—16-h.p. and 30-h.p. A chassis, a coupé, and a double phaeton of the former are included in the exhibit, as well as a 30-h.p. Limousine. The frames are of pressed steel, and the engines have the four cylinders cast in two pairs, and the valves arranged on each side, all being mechanically actuated. The ignition is by gear-driven magneto. A special form of metal-to-metal clutch is employed; the transmission is by side chains, four speeds and a reverse being provided. In the 30-h.p. car the drive is direct on the third and fourth speeds.

Digitized by Google

For the 1905 season the ROCHET-SCHNEIDER Co., of Lyons, for which Messrs. Donne and Willans, Limited, are the British agents, is confining its attention to two models of four-cylinder cars, 24-30-h.p. and 35-40-h.p. Both types have pressed steel frames of sufficient length to permit of side-entrance bodies to be fitted. The 24-30-h.p. has its engine cylinders cast in two

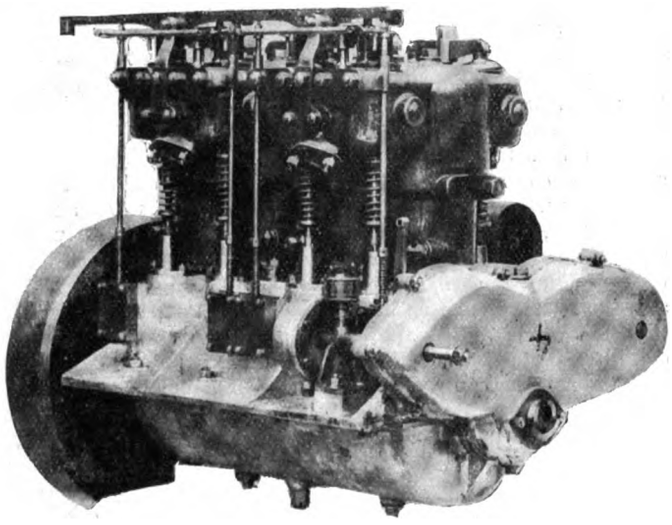

Fig. 34.—The Rochet-Schneider 24-30-h.p. Motor.

pairs, the water jackets being part of the casting. The dimensions are 120 mm. bore by 140 mm. stroke. The motor of the 35-40-h.p. car, on the other hand, has separate cylinders, each 140 mm. dia. by 160 mm. stroke. In other respects the cars are on similar lines, so that the following remarks apply to both types. The inlet valves are mechanically operated and are interchangeable with the exhaust valve. A device is now fitted whereby, on placing the starting handle in position, the compression is automatically released, so facilitating the starting of the engine. The low-tension system of magneto ignition is still retained, a device being provided whereby the ignition of each cylinder may be tested separately. The water is circulated by a gear-driven pump through an improved form of honeycomb radiator with fan; the latter runs on ball bearings, and is driven by an adjustable belt. All the gear wheels, including those operating the pump and magneto, are entirely closed. The mixture is furnished by an automatic carburettor of the company's own design. The change-speed gear has been considerably modified, the two shafts being now arranged in the same horizontal plane. Four speeds forward and a reverse, with direct drive on top speed, are provided, the transmission from the differential countershaft being by side chains. The clutch is of the metal-to-metal type, arranged in such a way as to give a gradual engagement. The steering gear, which is of the worm and worm wheel type, has been considerably strengthened. In addition to the usual hand-operated internal expanding brakes connected with the hubs of the rear wheels, two pedal-operated brakes are mounted on the countershaft. The axles are of nickel steel of H section, while the equal-sized road wheels run on ball bearings. In addition to a 24-h.p. *chassis*, two beautifully-finished side-entrance limousines—one of 24-30-h.p., and one of 35-40-h.p.—are shown.

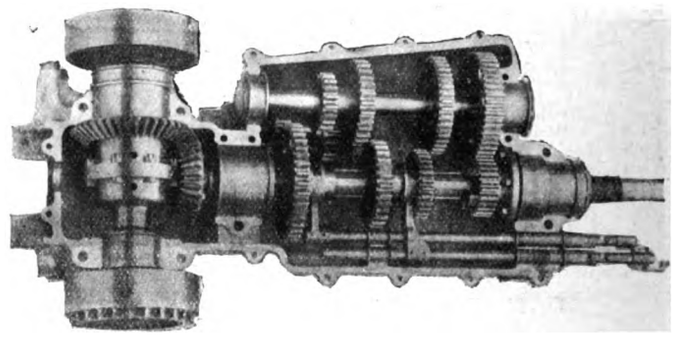

Fig. 35.—The Rochet-Schneider Change-Speed Gear.

A new-comer among electric motor-carriage builders is M. ALFRED DININ, of Puteaux, represented in this country by Mr. André Godin. Three cars are shown, differing only as regards the bodies. Outwardly the vehicles have the appearance of petrol cars, a false bonnet being provided in front of the dash. The battery consists of 42 Dinin accumulators, two-thirds of which are carried at the rear and one-third under the bonnet, the capacity being sufficient for a run of 100 kilometres at a speed of 30 kilometres per hour. The control is obtained through one pedal; when fully depressed it applies a brake on the rear wheels, and as the pedal is released the power is increased until, at the top speed, the foot can be removed from the pedal. By means of a two-way switch on the steering wheel, the current can be cut out or switched to the positions for forward movement and for reverse. An arrangement blocks the switch, so that the current cannot be switched on unless the pedal is depressed. One electric motor is employed, this driving the rear axle through spur gearing. The cars have a neat appearance and are relatively light, the two-seated vehicle weighing complete with battery only about 11½ cwt.

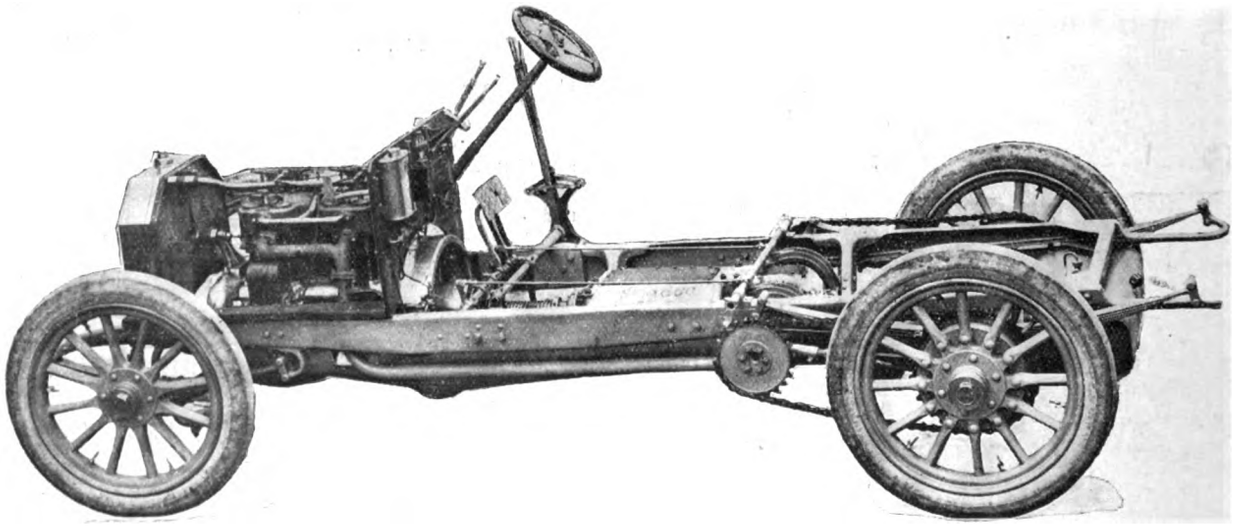

Fig. 36.—View of Chassis of Rochet-Schneider 24-30-h.p. Car.

Digitized by Google

The petrol car without a change-speed gear, briefly referred to in a recent issue of the *Journal*, forms one of the attractions of the Exhibition. The car, which is known as the "Direct," is to be seen at the stand of LA SOCIETE DE CONSTRUCTION MECANIQUE ET D'AUTOMOBILES, and has been built to the design of M. R. Goldschmidt. The frame is of pressed steel, and, so far as the general arrangement is concerned, the vehicle follows that adopted in chain-driven cars. The motive power is supplied by

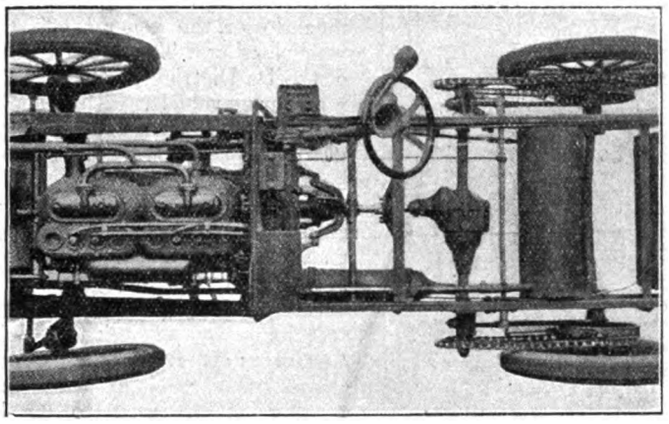

Fig. 37.—Plan of "Direct" Car with no Gear Case.

a four-cylinder engine developing 40-50-h.p. The valves are mechanically actuated, the feature being the arrangement of the cam shaft, which is such that the direction of rotation of the engine can be reversed. The shaft can be slid longitudinally, in order to bring a second set of cams in operation, the change being made by means of a small lever on the steering wheel. The cams themselves are of a special form, enabling the time the inlet valves are kept open to be varied, so regulating the amount of mixture admitted to the engine, and consequently the speed of the latter. The clutch is of a special metal-to-metal type. It consists of three steel discs one round the other, which can be progressively pressed together against the flywheel. The pressure is regulated by four compound levers worked by a sliding cone-shaped sleeve operated by the pedal. Thus the innermost disc is first brought into contact with the flywheel, as the pressure is removed from the pedal, then the second or central disc, and finally the third or outermost disc, the load being thus taken up gradually. From the clutch the power is conveyed by a jointed shaft to the differential shaft, and thence by side chains to the rear axle. It is claimed that the engine can be run at any speed from 80 to 1,100 revolutions per minute, and so drive the vehicle at a rate ranging from a crawl up to the maximum. The car has been subjected to a lengthy test in Belgium ere being put on the market, and we may add that arrangements are in hand for its introduction into England at an early date.

Another new-comer in the motor world is LA SOCIETE DES USINES DE DELAUNAY-BELLEVILLE, the well-known boiler makers of St. Denis. Three sizes of four-cylinder cars are being made—16-20-h.p., 24-28-h.p., and 40-45-h.p., the first-named having a bevel gear and live axle drive and the others side chain transmission. The exhibit at the *Salon* consists of a *chassis* of the largest type, and so surrounded was it by interested admirers that it was only with difficulty that we could get an opportunity of inspecting it. The frame is, as in all modern large cars, of pressed steel. The engine has four separate cylinders, 130 mm. diameter by 140 mm. stroke, with the inlet valves arranged on one side and the exhaust valves on the other, all being mechanically actuated. The ignition is by low-tension magneto, while the water circulation is maintained by a gear-driven centrifugal pump and a framed ribbed-pipe radiator. The latter is circular in shape, like the Hotchkiss, and the belt-driven fan covers the whole of the rear surface. The engine, which is lubricated by oil fed under pressure by a valveless oscillating pump, driven off the crank shaft, develops 40-h.p. at 900 revolutions per minute, but can be accelerated to 1,300 revolutions. The power is transmitted through a leather-faced cone clutch, a gear-box giving four speeds forward and a reverse, and side chains. The brakes are of the metal-to-metal type, that on the countershaft being water-cooled. Ball bearings are used throughout, with the exception of the engine. The front axle is of novel design, as not only is it bent in curves after the Mercedes fashion, but has an additional forward sweep in the middle. The usual longitudinal springs are supplemented by a transverse one at the rear. The lock of the front wheels is, it is claimed, such as to enable the large car to turn completely round in a circle of eleven yards diameter. A small knob is provided near the starting handle, by pulling out which the compression can be released to facilitate the starting of the engine. In connection with the discussion at present taking place in the correspondence columns of the *Journal*, it is interesting to note that no fewer than four pedals are placed close to one another on the footboard. The pedals from left to right control respectively the throttle, the clutch, a ratchet sprag to prevent the car running backwards, and the clutch and foot-brake together. Levers on the steering-wheel controlling the throttle and ignition are also provided. The workmanship throughout is of the highest class, the makers having evidently entered the industry with the firm object of bringing the "E.D.B." car, as it is known, into the front rank of automobiles.

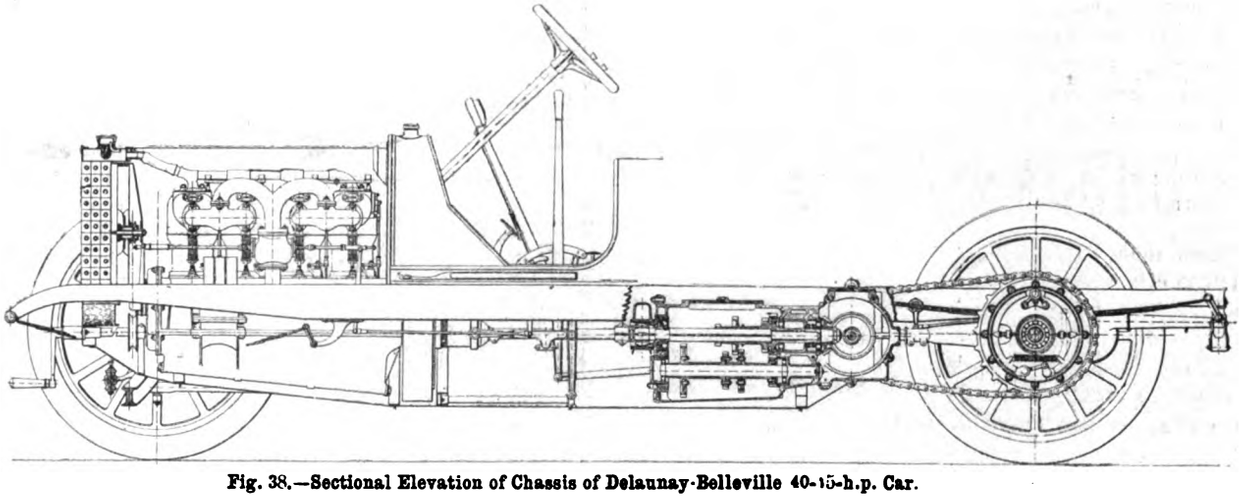

Fig. 38.—Sectional Elevation of Chassis of Delaunay-Belleville 40-45-h.p. Car.

Digitized by Google

The DE DIETRICH stand is one of the most striking in the Exhibition. The sign is of iron construction with revolving centre announcing the name of the firm. As a point of interest we may mention that the sign, with its electric lighting, cost upwards of £1,000. For the 1905 season four types are being made, viz., 16-h.p, 24-h.p., 40-h.p. and 60-h.p., in which several striking alterations and a number of important modifications have been made, and which were pointed out to us by Mr. C. Jarrott. The length of the wheel base of all the cars has been increased and they are now arranged for the fitting of side-entrance carriage bodies. The appearance has been considerably changed by the adoption of a honeycomb radiator of a new and ingenious pattern. Cooling is assisted by a belt-driven fan, the flywheel being also of fanlike design to induce increased draught. The flywheel is of much larger diameter than hitherto, as also is the clutch. The motor itself is of an entirely new model. It is fitted with an improved carburettor with a very finely graduated throttle to enable the motor to be set to run at any speed. The throttle is worked by a lever arranged on the steering wheel, a second lever controlling the ignition. An accelerator is also arranged for easy and quick acceleration in traffic driving and starting up-hill. An ingenious device whereby, when the throttle lever is opened wide, the action of drawing out the clutch immediately throttles the engine, is another important improvement. On the 40-h.p. *chassis* we notice that a half-compression lever is provided for easy starting. The petrol tank is now of a flat shape and is placed at the rear of the frame, and can easily be filled without disturbing any of the passengers. The change-speed gear box is of a new pattern, and cardan joints are provided on the differential shaft to obviate any strain being transmitted to the gear box bearings, and for the same purpose a cardan joint is arranged between the gear-box and the clutch. Another drastic change is the fitting of ball bearings to the gear-box shafts and the road wheels. The side brakes are of a much lighter design than formerly; they are internal-expanding, and enclosed from dirt and mud. A compensating arrangement is fitted whereby equal tension is put upon the brakes on both the road wheels. The steering bar is now arranged behind the front axle; the foot pedals have also been changed, and are large and square, affording comfortable driving. A new type of bonnet, with low dashboard, sloping footboard, and sharper rake of the steering wheel, give the cars a considerably smarter and more stylish appearance than the old type, and as the *chassis*, to ensure stability, is much lower, the general effect is very pleasing. The great feature of the De Dietrich display is a 40-h.p. touring vehicle, which embodies a saloon provided with beds, seats, writing table, electric light, electric bells, and dressing-room. It is completely equipped with every requisite, and is one of the attractions of the *Salon*.

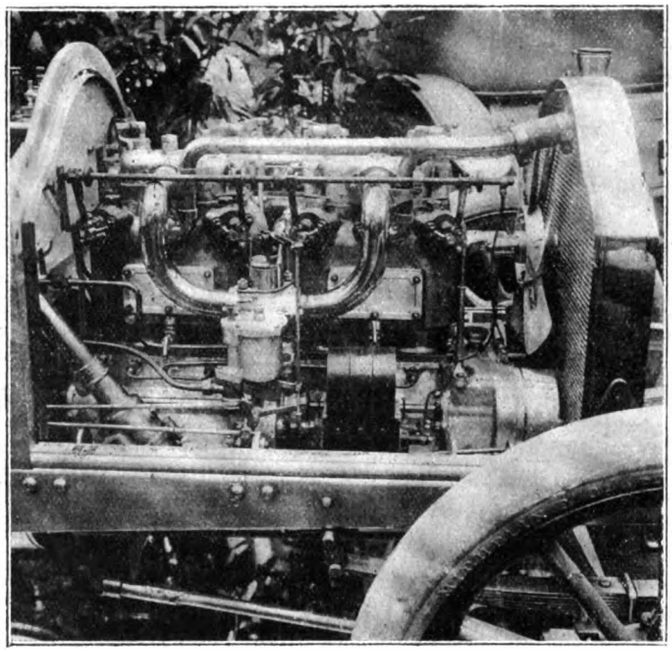

Fig. 40.—The De Dietrich 24-h.p. Motor.

M. L. BLERIOT makes a big display of his well-known acetylene lamps. The chief feature of interest is the new generator, all parts of which are, as was demonstrated to us by M. Norbert Chereau, readily detachable for cleansing purposes. The generator is intended to work with the cartridges or sealed tins of coated carbide supplied by this firm; this is placed in the generator, the tin being pierced by a pointed tube forming part of the cone-shaped top of the generator. The latter is hermetically sealed, enabling the lamp to be turned out and relighted as desired. One generator with its charge is estimated to give a light for six hours, but a lamp is made with two generators, so that twelve hours' light is available, the reserve set being used as an extra gas reservoir. The generators are also supplied separately in boxes containing one, two, or three sets. In the lamps themselves, which are made in a wide range of patterns, we notice some detail improvements, notably the fitting of an unbreakable glass chimney, by the use of which the reflectors are kept clean, and a new arrangement of double-hinged doors, one for the glass and one for the lens. A new adjustable lamp bracket is also worthy of notice, the two arms being bent in such a way that by unfastening a screw at the bottom the distance between the two may be easily regulated.

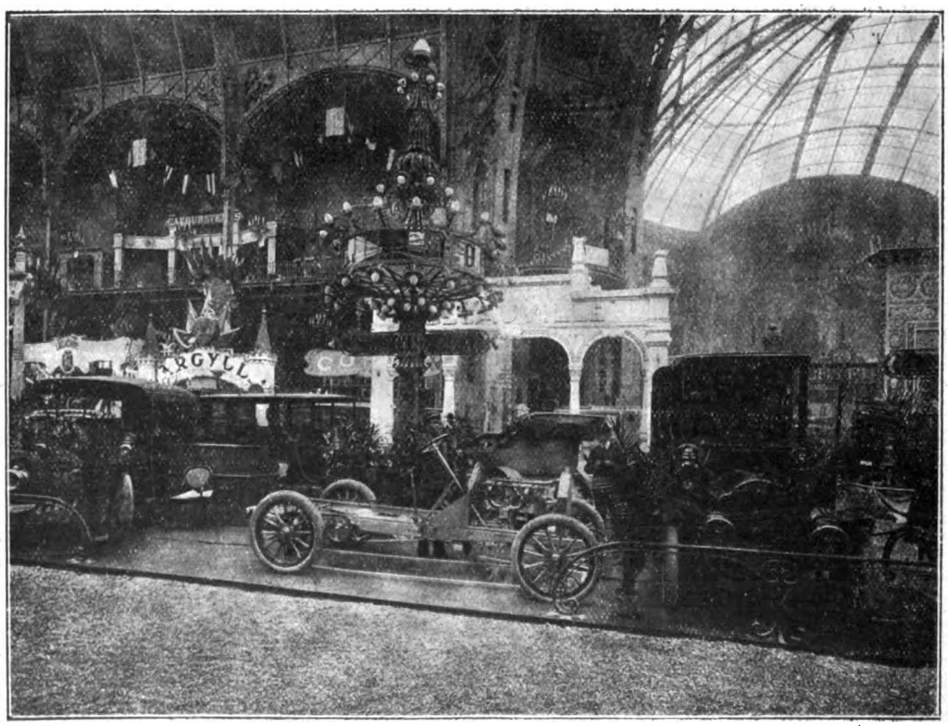

Fig. 41.—View of the De Dietrich Co.'s Stand.

(To be continued.)

HERE AND THERE.

THE Crown Prince Vladimir of Russia has ordered an Opel-Darracq coupé.

THE GREAT WESTERN RAILWAY COMPANY will run a motor-car service between Chippenham and Calne, commencing early next month.

DURING motor runs aggregating 4,000 to 5,000 miles ex-Councillor H. R. Gillham, of Redhill, has only had four punctures.

He was one of the earliest motorists in the district, and is shown in the accompanying illustration just starting for a spin with some lady members of his family.

"MOTOR CAR BODIES" forms the subject of the new list of the Lacre Motor Car Company, Limited, included in which are some stylish designs.

MISS PERRY, a Dublin motorist, has been charged at the police court with causing the death of a woman while motoring in Baggot Street, Dublin.

MR. MAURICE DE BREYNE, at one time well known in the London motor trade, will be found by motorists visiting the Riviera at the garage of the Auto Car Company, at Nice.

LORD BALCARRES, M.P. for the Chorley division of Lancashire, is making a motor-car tour through his constituency on a 12-h.p. Whitlock-Aster belonging to Mr. Timberlake, of Wigan.

WE learn that Messrs. J. I. Thornycroft and Company, Limited, have an order in hand for five 5-ton petrol lorries for Bombay. They are also supplying one of their 20-h.p. cars to Princess Christian.

THE first entry for the new race announced by the Automobile Club for tourist cars has been made by Messrs. C. S. Rolls and Company with one of their Rolls-Royce cars, described in last week's *Journal*.

A "WHITE" steam car has been presented to Mr. W. E. Scarritt, the retiring president of the Automobile Club of America, by the members of that organisation, in recognition of his services during his term of office.

A PUBLIC motor-car service has just been inaugurated between Yverdon and Moudon, Switzerland. The vehicles, which are of 20-h.p., were constructed by Messrs. Martini, and have accommodation for sixteen passengers.

"WILLING'S Press Guide" for 1905 comes again in a familiar form. Particular care has been given to presenting an accurate view of the press, not only of Great Britain, but also of the Continent and America. The care with which the compilation has been made will retain the work at the head of such publications.

THE Bradford Tramways Committee has ordered three motor-vans.

"THE CROWN" Hotel, at Kingsclere, has good accommodation for motoring visitors.

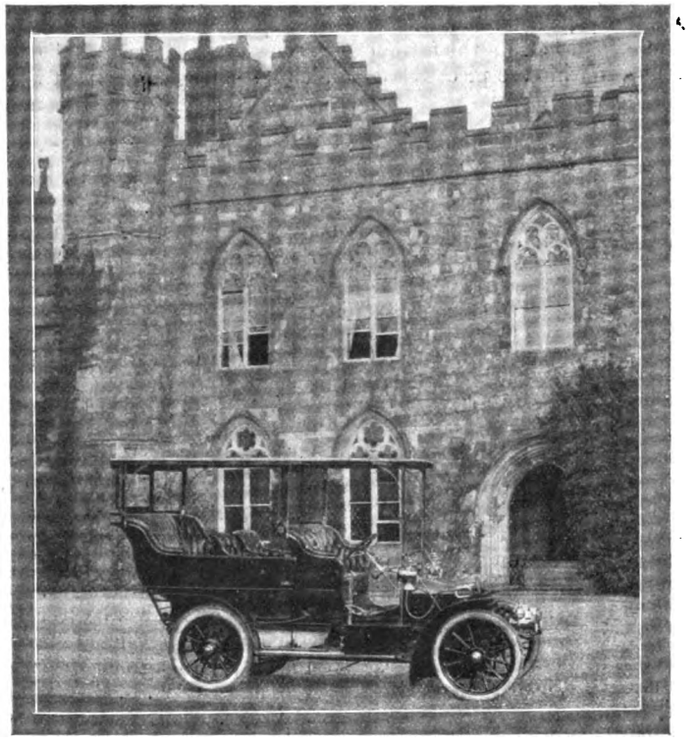
THE physicians of Paris are rapidly discarding horses for their professional work and taking up automobiles.

MR. T. H. HOLDING, of Maddox Street, W., has sufficiently recovered from his recent accident to be able to leave home.

THE Town Council of Pollokshaws has approached the Secretary for Scotland with a view to a restriction of the speed of motor-cars passing through the borough.

THE "Stepney" patent wheel, recently described in our columns, has been adopted by Lord Iveagh, the Hon. G. N. Irby and Mr. J. C. Drew, of Wadhurst Hall, Sussex.

LA SOCIETE DES VOITURES ELECTRIQUES VEDRINE is the name of a new company which has been formed in Paris with a capital of £6,000 to manufacture electrical motor-cars.



THE Giffnock (Scotland) ratepayers' committee is inviting the County Council to secure the limitation of the speed of motor-cars passing through that district to ten miles an hour.

THE TRAMWAYS AND LIGHT RAILWAYS ASSOCIATION are petitioning the Board of Trade with a view of securing the extension of the speed limit of twenty miles an hour to tram-cars.

A REQUEST is to be made to the Great Eastern Railway Company to run a motor-'bus service between Hornchurch and Romford railway station, to meet the trains both morning and evening.

THE Earl of Selborne, First Lord of the Admiralty, visited Portsmouth the other day, and proceeded in his motor-car to the Royal Marine Artillery Barracks, where he made an inspection of the Royal Naval School of Music.

THE accompanying illustration depicts Mr. Grace's 24-h.p. Wolseley, fitted with a special body by the Lacre Motor Car Company, Limited. The car, which can seat seven persons, is

luxuriously upholstered in green. The background of the picture is Battle Abbey, Sussex, Mr. Grace's latest residence.

AN attractive stand at the Paris *Salon* is that of the "General Accident" Company, of Perth. It is in a prominent position in the Grand Palais, and is decorated throughout with Rob Toy tartan relieved by silver badges of the Scotch thistle and the arms of Perth.

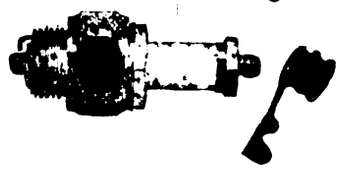
THE Civil Service Motor and Cycle Agency, Limited, are putting upon the market the neat little idea in sparking plugs which is shown in the accompanying illustration (Fig. 1), and which they call the Service Quick Snap sparking plug. As will be readily seen, the cap fits on like a glove fastener, and is always ready to hand, saving the time and trouble of looking for the fixing screw, as has to be done with the ordinary sparking plug. In connection with sparking plug connections, reference may also be made to the device shown at the Paris Salon by M. Ruffier, of 20, Rue Galvani, Paris. Instead of a glove-button fastening,



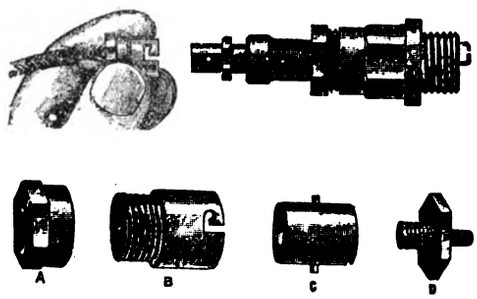


Fig. 1.

Figs. 2 and 3.

M. Ruffier has adopted the bayonet fastener, on the lines of that adopted in connection with electric incandescent lamps. Reference to Figs. 2 and 3 will show that it consists of four parts—A, to which the high-tension wire is attached; B, one part of the fastener which screws into A; D, a double screw piece, which at one end is screwed into the plug and at the other receives the second half of the fastener C. The latter has two projecting studs. Within the piece B is concealed a small spring, so that when the attachment is made there is no danger of it becoming detached owing to vibration or jolting.

IT is stated that no less than 1,900 men are at present employed at the works of the Daimler Motoren Gesellschaft at Unterturkheim, where the Mercedes cars are built.

MR. SHIELL, of Perth, has supplied Messrs. J. Pullar and Sons, of the dyeworks there, with a motor delivery van of 9½-h.p.

A RESIDENT of county Kildare has obtained a verdict for £15 and damages against a Dublin motorist for injuries caused to him and his pony trap by the defendant's motor-car.

THE Speedwell Motor and Engineering Company, Limited, announce that they have entirely remodelled the whole of the Speedwell series of cars for 1905. They have a comprehensive range of models, commencing with a light 6-h.p. car, and extending up to the imposing 25-h.p. touring Speedwell.

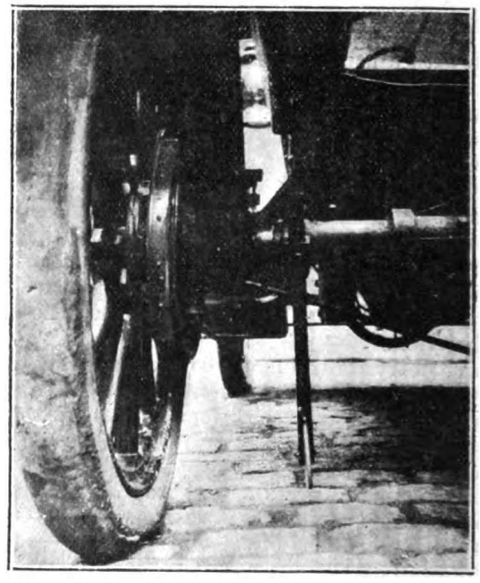
OWING to the pressure of work as managing director of Clement-Talbot, Limited, Mr. D. M. Weigel informs us that he has been forced to resign his position of managing director of the British Automobile Commercial Syndicate, Limited, of which concern Mr. F. F. Wellington has been appointed manager.

THE Warminster Motor Company, Limited, has been registered with a capital of £5 000, to carry on the business of manufacturers of motor-cars, etc., and to adopt an agreement with Mr. L. C. Willcox. The first directors are Messrs. L. C. Willcox, R. Hopkins, H. T. Cookson, and F. Garton. The registered office is at 21, George-street, Warminster.

AT Caxton Hall, Westminster, Mr. John Troutbeck, sitting as high bailiff, with a special jury, heard the case of "Mills v. the London County Council," which was a claim for compensation for the compulsory acquisition of certain premises in Horse and Groom Yard, Wood Street, Westminster, used as a motor garage, required by the Council in connection with the Thames Embankment and Westminster Improvement scheme; £622 was awarded.

A REXETTE car will be on exhibition at the Turin show next month.

THE A. G. Mulliner Motor Body Company, Limited, have removed to Rimrose Road, Bootle.



WE learn that Messrs. Clement Talbot, Limited, have decided to fit the whole of their output during 1905 with Clincher tyres.

A MOTOR transit scheme between Gorey and Enniscorthy, in North Wexford, is being advocated locally, and financial support is apparently being secured.

ACCORDING to a statement issued by the Provincial Secretary of Ontario, 604 new automobile licences have been issued in that province since October, 1901. This is an indication of the growing popularity of motoring in Canada. It has taken hold in earnest of the wealthier class of citizens, many of whom are now enthusiasts. At present discussion is rife on the subject of new cars, and judging by current talk there will be a regular boom in motoring in Canada next year.

THE annual report of General Greely, the Chief Signal Officer of the United States army, which has just been submitted to the United States Secretary of War, contains some reference to automobiles. The General says, in substance, that the evident value of motor-propelled vehicles as parts of telegraph and balloon trains has led him to continue experiments with automobiles. While motor-cars in their present state are evidently unsuited for general transportation in the field, yet the experiences of the signal corps have demonstrated the practicability and advisability of self-propelled vehicles for special military purposes. While the good points of electric and steam vehicles are thoroughly recognised, yet the internal combustion type, using kerosene or other oil, seems better suited for war purposes.

A NEW puncture tell-tale device is being introduced by Mr. H. Hunt, of 141, Essex Road, Islington, N. As will be seen from the accompanying illustration, it consists of a lever supported from the back axle and terminating in a light rubber wheel. The lever is adjustable as to length, and is so arranged that when the tyre is fully inflated the rubber wheel is clear of the ground. Should the tyre be punctured and consequently deflated, the rubber

wheel is lowered until it eventually touches the ground. The spindle of the rubber wheel is carried in the lever in such a way that when contact with the ground is made it is raised in its supporting slots, so completing an electrical circuit and causing an electrical bell near the driver's seat to ring. It is intended that each of the rear wheels should be provided with its tell-tale device, which, as will be seen from the illustration, is not unsightly, and adds but slightly to the weight.

IMPRESSIONS OF THE PARIS MOTOR-CAR EXHIBITION.

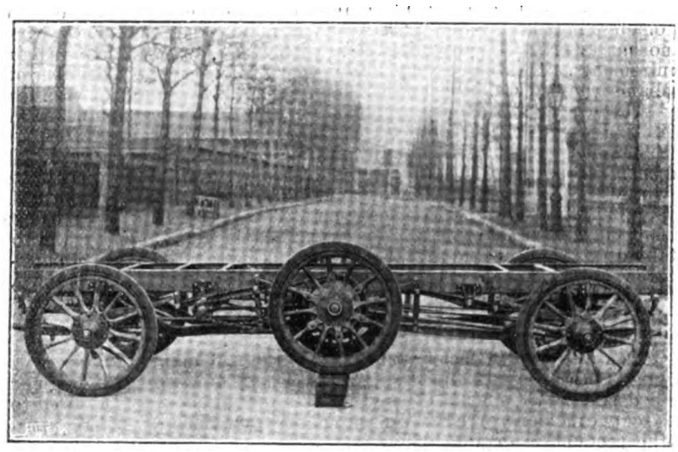
By S. F. Edge.

I THOUGHT it might be of interest to give my impressions of the present French Automobile Show. These impressions are of a most pleasant description, particularly looked at from a British point of view. The show itself as a spectacle is unequalled. The building is magnificent, and I am afraid cannot be reproduced in this country. The scheme of electric lighting is everything that an artistic eye can ask for, and even on this point I think we shall have great difficulty in this country in equalling our French friends. Their arrangement of bands and music could not be bettered, and the money lavished by the individual firms on the decorations of their stands I do not expect to see equalled over here for many a long day, if ever, as they only appear to advantage after darkness has set in, at which period people interested in buying and investigating motor-cars generally go out, it apparently being found that when the lights go up it brings such an enormous crowd of enthusiastic sightseers to listen to the band and to see the illuminations that the reason and cause of the Exhibition is completely forgotten.

I think the French are unquestionably very wise in trying by every means in their power to increase the prestige and success of their Exhibition, but at the moment I am of opinion that this lavish expenditure on the stands and beautiful decorations of the building are tending to make the show too much of an attraction to the franc-a-time sightseer rather than the serious mechanically-minded person or would-be buyer of an automobile, as the time is now restricted to a few hours in the morning, when he can see the exhibits with some degree of comfort undisturbed by the sight-seeing crowd.

When we come to deal with the exhibits themselves, the motor-cars, coach-building, engines and boats, as the case may be, we find every cause for satisfaction from a British point of view. There are no sweeping improvements or striking changes. The French brains which have done so much for the automobile industry appear to have run to their limit on broad lines for the moment, and it is open for any good engineering firm with motor-car knowledge to-day to start and build a car practically as good as the best French production, without feeling when doing this that by the time their car is produced it will be out of date. This marking time on the part of the French manufacturers has enabled other manufacturing countries to catch them up, with the result that we see to-day alongside with French productions motor-cars from Germany, Italy, Belgium, America, and Great Britain equal in design, workmanship, and price to the best that France can produce, so that we are now in the position of these countries toeing the starting line for 1905 on an equal basis, with equal knowledge, and in the case of some countries with a superiority of machinery and workmen.

There is a curious backward tendency in one direction in France, and that is to see that the weights of the *chassis* are rising very rapidly. One has only to look at four or five of the leading firms' exhibits to notice that their *chassis* are considerably heavier for 1905 than they were two years ago, even allowing for the increase of horse power. This points to the fact that the superiority originally claimed for France that they could build lighter vehicles than other countries to do the same work was not quite justified, but that merely owing to their great reputation people believed that a hundredweight of French material would stand more than a hundredweight of material supplied by another country. Time has proved that this was wrong, and the French manufacturers are now making desperate efforts to get even with those countries which put the necessary weight into their vehicles to give them lengthy wearing qualities.



Another point in which France seems to have dropped behind, if we except one or two firms such as De Dion and Peugeot, is the manufacture of the small single-cylinder car, cheap both in upkeep and prime cost, and the example in this direction shown by a British firm, the Wolseley, is something to be proud of, and we realise that in the small car trade France has practically, with the two exceptions above referred to, dropped back. In medium-priced four-cylinder cars I think France to-day still holds an exceedingly strong position, and through the enterprise and engineering skill of two or three firms still looks like holding her own in this direction.

From a coach-building point of view, many of the vehicles are beautiful, have fine lines and perfect finish, nothing strikingly original, however, and none of the workmanship better than can be given by the leading English firms; in fact, speaking as a carriage-body buyer in the high-class trade, I can actually get pound for pound better value in this country than I can in France from the highest class builders in that country.

The motor-boat section is disappointing, to say the least of it; there is nothing original or new shown at all. Most of the boats are both rough and cheap, and there are many English boat builders whose work is far in advance of the bulk of that which is shown, and I think it will be found that at the forthcoming English shows far better samples of pleasure motor-boats will be on view than the best shown in France.

When we come to the machinery section, it is very interesting to note that of the large number of gas engines in use only three are of French manufacture, nearly all the others being of English make. Of the special motor-car tools in use, practically all are English or German.

It is interesting and satisfactory to note that there are still French firms adhering to the obsolete method of transmitting large horse-power through leather-lined clutches. The Panhard Company have in their newest model adopted the metal to metal clutch, and undoubtedly every firm must do the same for high-powered cars, and will, I think, eventually do it for every power car. To give a little example of what appears to me to be a desperate effort on the part of some of the French firms to alter their vehicles from last year without improving them, what can one see worse than a firm who actuate their inlet valves from the top of their cylinders with rocking levers, and who do not take advantage of the valve being on top by placing it over the exhaust valve so that the inrushing fresh mixture may tend to keep the exhaust valve cool? It seems to me no better example can be shown of their efforts to be different to other people without really having a material advantage to offer.

The Renard Road Train.—View of six-wheel Compensated Trailer.
(See page 872 last issue.)

THE entry list for the American team for the 1905 Gordon Bennett race closed on the 15th inst., and we learn by telegraph that only three cars had been entered, these comprising two 90-h.p. Pope-Toledo cars and a 90-h.p. Locomobile petrol vehicle.

THE Stevens Motor Manufacturing Co., Ltd., has been registered with a capital of £5,000 to acquire the Stevens Motor Manufacturing Co., at Tempest Street, Wolverhampton. The first directors are Messrs. J. Stevens, W. Barnett, and W. H. Haden.

CORRESPONDENCE.

THE PARIS EXHIBITION AND THE BRITISH AUTOMOBILE INDUSTRY.

To the Editor of *The Motor-Car Journal.*

Sir,—I should like in a few lines to give my impressions of the Paris Exhibition, and in connection therewith developments which undoubtedly affect the British automobile industry. In the first place it is pleasant to note that all the leading makers have made no decided alterations for next year's models. The modifications one sees are only what may be expected by the process of evolution. Probably the most striking development is the general adoption of magneto ignition in some form or another. I look upon this lack of important or radical alterations as one which is of the greatest importance to English manufacturers, as it goes to show that the trade generally is sure of its ground and that the types already existing have proved successful. Radical alterations only tend to increase the manufacturer's risk and make the buying public very undecided. A general uniformity of design cannot but be helpful to the intending purchaser and the trade generally.

The feature of the show is, however, to my mind, to be found in the galleries, and I think that an inspection of the same is well worth the visit to Paris. Here one found the source from which the French manufacturers and a great many English manufacturers obtain their supplies of forgings, castings and accessories, as of course it is impossible for any manufacturer, either foreign or English, to make every part of the machine in his own works. In addition to the large number of makers of electric fittings, radiators, lubricators and scores of other accessories, there were a large number of exhibits of steel and iron parts, both in the forged and finished state. Several of the largest steel and iron firms in France, Belgium, and Germany had most interesting exhibits of steel, etc., required for motor-car construction. These samples were exhibited in a way which appeals to every manufacturer, and it would appear to me that the steel manufacturers of the Continent are fully alive to the importance of the automobile industry, and are assisting the manufacturers of motor-cars in no small degree, by providing them with materials suitable for their requirements. I have noticed year by year in Paris that the number of steel and iron firms exhibiting increases, but I have looked in vain for any great English firm coming into the market on the same lines and exhibiting their goods either at the Paris or other exhibitions.

There is no doubt in my mind that the French industry has prospered and been encouraged to a great extent by the enterprise which has been shown by such firms as Lemoine, Krupps and many other continental firms. It is in my recollection that some years ago I was obliged to buy axles from abroad for the reason that I could get no English firm to take up the matter and give the same quality as the foreign manufacturer. I was, of course, informed that the English goods were the best, but when it came to a question of having the two articles tested, the English manufacturer had to admit that he was beaten—and he will remain beaten if he does not show more enterprise.

It is a well-known fact that nearly all English manufacturers still buy many of the component parts from abroad, either in the rough or finished state. This is not the state of affairs that should be allowed to exist for one moment. We have in this country everything that is required for the production of the highest class type of motor-car. We have skilled steel manufacturers and iron founders, who are well able to do whatever can be done by the foreigner, and more if they desire. I know that several large firms of steel manufacturers have been approached to take up the question of the manufacture of special steel for motor-cars, but they certainly have not shown determination or gone to the expense in experiments to anything like the extent which we find on the Continent, where it appears that everything is done by firms dealing in specialities to give motor-car constructors the very best article that science and skill can produce. Hoping this communication will be the means of ventilating this subject, which at the present time in my opinion is of the utmost importance to the British automobile industry.—Yours truly,

J. S. Critchley.

AN INTERESTING MOTOR QUERY.

To the Editor of *The Motor-Car Journal.*

Sir,—I observed in your issue of the 10th inst. a letter signed "Inquisitive One," in which the writer states that, after sundown on a bright, warm day, he has noticed a distinct increase in the power of his engine. It is owing to the appearance of a reply to this from the Economic Company, the perusal of which forces one to suspect the perpetration of the gentle hoax, that I am moved to try and supply your correspondent with the true explanation. Assume the engine running full power and the atmosphere dry. Then a perfect carburettor will supply a full charge of exactly such proportions of petrol vapour and air as will result in complete combustion. Now if we suppose the atmosphere to hold a certain quantity of water vapour in suspension, as is the case in damp weather, I think consideration will show that for every reason loss of power will follow: For (1) the atmosphere is less dense and there is less pressure to force the charge into the cylinder, (2) the water vapour will be converted into steam on entering the hot cylinder, and so greater resistance to compression will be offered, (3) the heat developed by the first part of the explosion will be taken up in part in expanding the free steam, and combustion will consequently be checked, and (4) (most important of all), the air being less dense, there will not be the same proportion of oxygen available, and combustion will therefore not be complete.

In considering these points, the simple principle of the petrol engine should be borne clearly in mind, namely, that the mixture of petrol vapour and air, when ignited, burns and forms carbonic acid gas and water (in the form of steam), and that it is the expansion of these gases, caused by the heat generated on their formation, which gives the power. The greater the heat, therefore, the greater the power.

Now to apply the above (which, for clearness sake, has been necessarily rather long-winded) to the particular point raised by "Inquisitive One." On a bright, clear day the radiation of heat from the earth's surface is free and uninterrupted owing to the absence of clouds.

When the sun sets, this radiation is very rapid and quickly cools down the air in the neighbourhood. This fall in temperature causes a portion of the moisture in the air to condense and be deposited; consequently the air is rendered a more efficient component for the mixture, and any engine inhaling it should develop greater power.

This explanation is that given to account for the familiar phenomenon known as "fall of dew," and will be found in any text book on physics.—Yours truly,

Ayr.

To the Editor of *The Motor-Car Journal.*

Sir,—In reply to "Inquisitive One," in the *Journal* of the 10th inst., may I suggest two probable causes? I may say that I have exactly the same experience, and will try to explain to what I ascribe the increase in power. I come into town in the morning by about a seven miles run, and during the day have several runs of about eight or ten miles each. During the run home again, towards evening, I find the car has more power on hills and is much speedier on the level, actually seeming, as your correspondent says, "to take the bit in its teeth" and fairly romp home.

Now I believe, to get the maximum of work from a petrol engine, the cylinder must be hot (not overheated) and these short runs tend to thoroughly warm up the cylinder, thereby thinning the coating of lubricating oil, and, if the piston rings are in good condition and a good fit, allowing the piston to work easier (without loss of compression) than if the cylinder were cold and the oil therefore thicker, tending to clog the piston ring.

But not only this, the hot cylinder warms the gaseous mixture at points furthest from the point of ignition, making it of a more even and higher temperature all through, this I believe tending to quicker and more instantaneous combustion than would be the case if some portions of the mixture were of a lower temperature than others, the colder portions having more of a burning action than an explosive one.

Now, as a secondary cause, I have observed that on approaching the country from the town the engine runs better, due to the air being purer, this purer air aiding combustion owing to the greater proportion of oxygen which it contains.

I would suggest the theory, therefore, and would be glad of confirmation or correction, that during the day the sun absorbs a certain amount of oxygen from the air, varying in proportion as the sun shines brightly for hours or only intermittently, and that as the sun goes down and night approaches the air gets cooler, this cooler air containing a greater proportion of oxygen, therefore forming a better mixture.

To this I ascribe the fact that an engine developing a certain power requires less air in the colder months than in the warmer months to develop this power, the smaller volume of cold air containing about the same amount of oxygen as a proportionally larger volume of warm air.

Like your correspondent, I should be glad to have an expert's view on this matter.—Yours truly,

Wm. F. Fortune.

To the Editor of *The Motor-Car Journal.*

Sir,—I was very pleased to see in the *Motor-Car Journal* of the 10th inst. an interesting motor query) brought forward by "Inquisitive One." I have come to the conclusion that in the evening, as "Inquisitive One" says, the motor fairly takes the bit in its teeth. This is caused by the higher atmospheric gases that come from the leafage, trees, etc., which does not show itself in the day-time. This causes a richer mixture, a better explosion, and so more power in the engine. I should be very pleased to hear of other readers' views on this subject, as I feel sure there are many motorists who would like to hear this phenomenon explained.—Yours truly,

Saxilby.

REPAIR SHOP EQUIPMENT.

To the Editor of *The Motor-Car Journal.*

Sir,—I am starting a business for the sale and repair of motor-cars, in partnership with a working mechanic. We intend to build a garage for three or four cars, capable of extension when necessary. Can any readers of the *Journal* oblige me with any suggestions as to fittings, benches, etc., or any special tools likely to be useful? My partner has

Digitized by Google

already a very complete outfit of tools for motor-cycle repairing, etc We should have a difficulty in getting drainage for an inspection pit. Would a Webb's cradle do as well ?—Yours truly,

IN-26.

AN OLDSMOBILE QUERY.

TO THE EDITOR OF *The Motor-Car Journal.*

SIR,—I have a 1902 Oldsmobile, which has run exceedingly well during the short time I have had it, until one day last week, when it ran a few yards and refused to be coaxed further for a long while. On the previous day nearly a cupful of oil ran through the lubricator into the cylinder, owing to an oversight, and the car was not used until the next day, with the above result. I found the plug was covered with soot, and cleaned it. Started again splendidly, but soon stopped, and the same operation had to be repeated until the oil was all burned away. But although the engine ran well and strongly with the car standing, directly I got away on the slow gear and tried to go on the high gear the engine slowed down and stopped—seemed to have scarcely any power left. I examined the plug, but it was quite clean. Compression as near perfect as possible. Mixture as for usual running, although no amount of adjustment gave any improvement, and, strange to say, while the engine could just manage the slow speed with throttle closed, directly the accelerator was depressed the engine seemed to be choked.

The only solution I can guess at is that in cleaning the plug the points were forced too far apart, and a long thin spark resulted. Would this be sufficient to fire a small quantity of mixture, but not the full amount, when the speeder was open ?—Yours truly,

BOTHERED.

[We would advise "Bothered" to give his engine a good wash out with paraffin, as no doubt after the quantity of lubricating oil which passed into the cylinder, the valves, etc., are thoroughly gummed up; we should also advise the removal of valves and inspection of same, also the closing of the points of the sparking plug. The distance apart for the points should be approximately 1-32 in.]

THE SUNRISING HILL CLIMB.

TO THE EDITOR OF *The Motor-Car Journal.*

SIR,—We are pleased to see by this week's papers that the management of this hill climb admit an error in what at first sight appeared to be an almost unaccountable award. We are also glad that they have published the formula upon which the results were based, because it shows us the entirely erroneous and unfair factor which has been taken, and the reason for the placing of our car, which we could not previously understand. Seeing that our 12-h.p. car in actual results beat a number of cars of very much higher horse-power, we had expected to find ourselves figuring rather higher than lower in the list than shown by actual results, yet all the cars we defeated we find placed very much above us, and our own position is given very far down the list. Now we desire to protest against the factor of engine revolutions being used at all. Had we known the formula which would form the basis of the handicap we should certainly have declined to enter, and we desire to say that we shall never again enter any competition where we have to be judged by a secret and unpublished formula. Had the framers of the handicap taken piston speed as a factor we could have understood it, but to take 1,000 revolutions as the unit is most unfair to all cars such as ours with slow-speed engines. Our 12-h.p. engine gives its 12-h.p. at 600 revolutions, and it is not designed to run beyond 800 or 900, and it will not give proportionate results to engine speed at the higher rating. If you compare our case with that of a car fitted with an engine designed to run normally and give its power at 1,200 to 1,500 or 1,000 revolutions, it will be seen how very unfair to the slow-running engines such a "hit and miss" sort of formula must be. In future we trust that promoters of hill-climbing, and any other competitions which are not judged upon direct results, will, in fairness to the competitors, publish the formula upon which results will depend with the programme announcing the contest. Competitors will then be in a position to decide whether the handicap is a fair one or otherwise. In our case it was distinctly unfair, and we certainly should not have entered had we known what it was going to be.—Yours truly,

THE DURYEA COMPANY, LTD.

THE UNITED KINGDOM TROPHY.

TO THE EDITOR OF *The Motor-Car Journal.*

SIR,—Whilst congratulating the committee generally upon the very practical set of rules they have put forward for the above contest, may we point out that if these rules are to be considered final they will have the effect of shutting out several cars from any possibility of taking part therein, however much their makers may desire to do so; and as these cars are all essentially touring vehicles and it is the development of the touring car that the contest is intended to promote, it seems that the rules as they stand somewhat defeat the object of the whole proceedings. The particular clause which is insurmountable is that "The platform behind the dashboard shall not be less than 6 ft. 6 in. long nor less than 30 in. wide." Now, the first part of this clause would effectually debar either the Lanchester, the Arrol-Johnston, or the Duryea from taking part, for they have no "dashboard" at all, whilst the central and more or less elevated position of the engine in each results in there being no long "platform," as in the ordinary type of car. Another point to which exception may be taken is specifying that "Efficient mudguards to the front wheels shall be fitted to the *chassis*." Again, we hardly see the reason for the requirement that seats should be thirty-four inches from the ground. We take it the Committee do not want "freak" machines, but cars which, except in the matter of the size of the petrol tank, shall in every way be the standard vehicles of the competing firms. Further, we note the weight of the drivers is to average eleven stones, instead of the usual ten. Surely the better way would be to require that the weight carried, inclusive of the two occupants of the car, should be 950 lbs., and specify no particular weights for the passengers. As all cars have to carry the same net load, there would be no gain to a competing firm in selecting specially light men, because a live load always carries easier than dead weight, and as the rule now stands a firm whose best men for the job happen to weigh more than twenty-two stone together would be handicapped by their additional weight, as they would still have to carry "not less than 300 lbs. ballast."—Yours truly,

T. D. C. L.

ENGINE TROUBLES.

TO THE EDITOR OF *The Motor-Car Journal.*

SIR,—In answer to "A Reader of the *Journal's*" letter in the last issue, it would appear to me that upon fitting his new cylinder he still used his old connecting-rod. If this is the case, he will undoubtedly find that the piston does not go high enough up the cylinder to give the proper compression; this would cause the irregularity in running. Failing this to be the cause, he might turn his attention to the flywheels, as ¾ in. is a great increase in the cylinder-bore, the existing wheel only being sufficient for the previous-sized cylinder. The water circulation has, no doubt, a syphon formed by having the pipe bent down to such a great degree, or perhaps the pump is not large enough to maintain a sufficient supply of water in the increased size of jacket. The lubrication would be greatly aided if a small quantity were occasionally put into the crank-case in addition to that which is fed from the lubricator. The silencer is, without doubt, too small for the size of engine, and should be quite double the size.—Yours truly,

H. J. T.

PISTON RINGS.

TO THE EDITOR OF *The Motor-Car Journal.*

SIR,—Could you or any of the readers of the *Journal* tell me the correct method of turning piston rings for petrol motor engines? I am a turner and have a small car to drive; my foreman insists that I must turn the rings somewhat larger than the bore of the cylinder, and then split and file at the joint until they go in. I was always under the impression that to have a piston ring a perfect fit it should be turned larger than the cylinder, cut a certain amount out, close the ring together and then turn the exact size of cylinder; also set ring in the lathe so that the thinnest part is at the joint to give the ring a good tension. I should be pleased if anyone could give me some advice on the subject.—Yours truly,

A MECHANIC.

["A Mechanic's" method of turning piston rings is the correct one. It is, however, very seldom practised, the other method being much cheaper.]

THE DURYEA CAR.

TO THE EDITOR OF *The Motor-Car Journal.*

SIR,—Will any private owner of a 12-h.p. Duryea car kindly answer the following questions: Is the power drum satisfactory? Is the steering gear strong enough? How many miles can be run on a gallon of petrol? Is it generally a satisfactory car for a moderate speed over very bad roads?—Yours truly,

Y.

THE USE OF THE ACCELERATOR.—FOOT v. HAND CONTROL.

TO THE EDITOR OF *The Motor-Car Journal.*

SIR,—With reference to the article by Mr. Percy Richardson, in the *Journal* of the 10th inst., I am glad that he agrees with me on this subject. What he says as to the likelihood of accidents caused through the accelerator pedal being pressed down in cases of emergency instead of the brake pedal is quite true, as it is at such moments that one's eyes are on the road, and should the driver lose his nerve for an instant an accident would very likely be the result of his using the wrong pedal. Excellent though the system fitted to the Fiat cars is, it certainly has the above disadvantage, and fitting three pedals close to one another to be worked by two feet is bad practice. I await with interest further particulars of the car Mr. P. Richardson has designed and constructed, in which he states he has perfected a method of control for the engine which does away with all hand levers and only necessitates two foot levers. Simplicity of control should be a leading feature in a car, and the invention in question is of great importance, and will assuredly be

Digitized by Google

received very favourably. I trust Mr. P. Richardson's invention will receive the support it deserves, as it is yet another step towards perfecting that truly wonderful thing, the modern motor-car.—Your truly,

R. G. PRIEST.

TO THE EDITOR OF *The Motor-Car Journal.*

SIR,—Referring to the article in your issue of the 10th inst. on the use of the accelerator or foot and hand control, the arrangement which I find very excellent and which I use in Napier cars is, to have the governor so arranged that the car will give very fair speeds—say from one half to two-thirds of its maximum speed—without using the accelerator, but if higher speeds than this are required then the accelerator must be brought more or less into use.

I think that the car which depends upon hand control only to prevent the engine from racing is bad in every respect, as it means that before one can change speed you have actually to make a movement with the hand—the accelerator is placed on the right hand side of the car, which means that when you apply the foot brake the foot has to be taken off the accelerator, so that automatically the speed and power of the engine is reduced immediately one puts on the foot brake. You then have your hand control for slowing the engine down or reducing the power below that which it is set at as much as you like, but you cannot increase it up to a dangerous extent by the use of the hand control only. The dangers of hand control only are not sufficiently understood; just think for one moment what it means when your hand control is full open on a type of car that is not governor controlled: the driver may be going along very fast, he comes suddenly to a corner, he withdraws his clutch, and one hand also being occupied in putting on the side brake and one in steering, the engine immediately races away at terrific speed and the gyroscopic action of the flywheel is, in my opinion, sufficient in many cases to cause those mysterious accidents which occurred abroad last year. It is only necessary to work out the enormous power that the fly-wheel can exert in keeping the car in a straight line to see the dangers of hand control alone.—Yours truly,

S. F. EDGE.

EMPLOYMENT REGISTRIES.

TO THE EDITOR OF *The Motor-Car Journal.*

SIR,—Recently, in response to an advertisement in one of the papers, I sent 2s. 6d. as fee for registration with an employment agency. Although I have since written several times I can get no reply, and write to warn intending drivers not to pay fees for registration. In fact, if they are wise, they will pay nothing until they are suited with a situation.

I have just heard of a case in which an agency claiming to find situations merely took names and addresses from your *Journal* and gave these to those men on their list, telling them to go and apply for the situations. For this half-a-crown was charged, whereas the applicants could have obtained more prompt information by looking down the columns of the *Motor-Car Journal.*

It seems a grievous shame that, at the beginning of a new industry, the outlook should be spoiled by the starting of agencies which, while professing much, do little for those who pay fees.

Whether the same remark applies to many of the schemes of motor instruction I do not know; but it is clear there are many abuses already creeping along, and I would advise everyone to keep their money in their pockets until secure in a situation.—Yours truly,

DRIVER.

HINTS RE DARRACQ CARS.

TO THE EDITOR OF *The Motor-Car Journal.*

SIR,—The following hints regarding Darracq cars may be useful to users of these vehicles:—

If the clutch is very fierce, a good dose of castor or other oil will generally stop it, and keep the leather in good condition.

The commutator.—This does not need much attention beyond the cleaning and adjustment of the platinum pointed screws once in every 200 miles or so.

The brakes are very good, and if cleaned with petrol every few days will give no trouble at all; the side brake should be used with caution, as, if used roughly, it will cause wear on the tyres.

The accumulators require charging once every 1,000 miles or so. It is much the best plan to pay a little more and get them done well than get them spoilt at the cheap man's hands.—Yours truly,

CHAS. STORR.

TUITION.

TO THE EDITOR OF *The Motor-Car Journal.*

SIR,—I should like to bring an important matter before your readers equally concerning owners of cars, manufacturers and drivers. Many persons are giving driving lessons which only extend over a short period. What good is that to an intending *chauffeur*, probably a young man who has been a clerk or draper's assistant? He pays about £5 to be put on a car about three times in some quiet spot, and then is given a so-called certificate, and made to believe he is a really competent driver. Probably with luck he may get a situation with someone who has bought a new car, and who has never had a vehicle before. The result is that the owner and manufacturer suffer, one with expense of repairs, and the other with loss of reputation. Something ought to be done. It is the duty of qualified drivers to take the matter in hand and start a Motor Drivers' Union, each member of which should prove himself efficient.—Yours truly,

TERMINAL.

CHANGING IGNITION.

TO THE EDITOR OF *The Motor-Car Journal.*

SIR,—Will any reader kindly indicate the best plan for applying electric ignition instead of tube ignition to a Leon Bollée tandem? My difficulty is how to get the timing gear adapted.

I have thought of getting it applied on the main shaft between the body of the machine and the flywheel. This could be done by removing part or whole of the small collar which regulates the governor.

Again, it has occurred to me that a device could be attached to the inner end of spindle of the cam wheel. I do not approve of a chain inside the gear-box. Can anyone recommend a better plan?—Yours truly,

FREE MANSE.

IS NOISELESSNESS DESIRABLE?

TO THE EDITOR OF *The Motor-Car Journal.*

SIR,—Many motorists who are accustomed to driving both steam and petrol cars profess to find a disadvantage at times in the noiselessness of the former. Working through ordinary traffic the motorist experiences a constant need of making careless and thoughtless people aware of his approach. On many petrol cars this is automatically accomplished, as the noise of the engine and gear, etc., is generally sufficient to convey the necessary warning. Being a continuous sound it comes to the ear of the pedestrian or other driver without the shock of suddenness produced by the striking of an intermittent alarum. He is prepared for it in a manner, and has time to collect his wits. The steam car, however, approaches almost noiselessly, and if the driver is maladroit in sounding his horn, the effect may be discomposing. A pedestrian or horse driver roused from his road reverie by a strident alarm tends towards panic. To avoid producing these sudden shocks the motorist very often is constrained to keep sounding his horn continuously, and it is not pleasant to his ears. The bicycle is the only other noiseless vehicle on the highway, and riders have frequently found this property productive of accident. Every other vehicle makes a certain kind of noise, and this may often vary with the speed, so that the pedestrian, without looking round, can approximately judge of the pace at which such vehicle is approaching. This automatic noise reaches up side streets and cross roads, and warns approaching objects of its proximity. The driver of the noiseless vehicle, on the contrary, must look out for such crossings and openings and sound his horn, or something may crash into him. On the whole, perhaps, he is constrained to greater watchfulness. Far be it from my intention, however, to deprecate silence, for no one who has enjoyed the silent-running car will be inclined to consider the quality undesirable, though he may have to admit that it is not without its minor disadvantages.—Yours truly,

DEVONIAN.

INVICTA ACCUMULATORS.—The Invicta Motor Accessories Co., Ltd., 67, St. John's Street, Coventry, ask us to mention that they are the agents for the "Invicta" accumulators in this country.

GLADIATOR CARS.—Another "Inquisitive One" writes:—"Having had both back wheels of two 10-h.p. Gladiator cars go to pieces after very little wear, I should be glad to learn, through the medium of your paper, of other owners of these cars who have had similar trouble, as it would be interesting to know if this is a general fault or only confined to my two particular cars."

SPARE PARTS FOR AMERICAN STEAM CARS.—A West of England steam-car owner writes complaining of the difficulty of obtaining spare parts for American steam cars.

TIMING A MOTOR.—"Denham" writes:—"I should be very glad if any of your readers would inform me how to time a single-cylinder engine; it has tube ignition."

MAGNETO IGNITION.—"Aitch Emm" writes:—"I should like to know if there are any books published dealing with magneto ignition: especially the Simms-Bosch high tension; also induction coils as applied to motor-cars."

ANONYMITY.—Under the *nom de plume* of "Purity" a correspondent writes from Glasgow, but does not send his name and address. We do not publish letters from correspondents who omit these particulars.

THE LOCOMOBILE.—A Croydon correspondent asks if the Locomobile is easy to manipulate and a good hill-climber. He also wants to know if the boiler is a cause of anxiety.

GAS ENGINE OPERATION.—J. Melville writes:—"Can any of your readers say if it is possible to work a 4-h.p. Tangye gas engine with petrol or acetylene gas? If so, what kind of fittings would be required?"

STEAM WAGON INSTRUCTION.—A correspondent wants to know how to obtain competent instruction in driving steam wagons.

Digitized by Google

THE GRAPHITIC LUBRICATION OF PETROL MOTORS.

By F. N. Blake.

On account of the great heat to which it is subjected, and also because of its need of thorough lubrication, the cylinder of a petrol motor is a most appropriate place in which to use such an indestructible and efficient lubricant as graphite. It is unfortunate that there are difficulties in the way of feeding it continuously, in the same manner as oil is used; if mixed with oil it obstructs its flow through the ordinary oil cup, and soon settles and stops the flow altogether, thus defeating the purpose it is intended to serve. Fortunately, the intermittent use of graphite is attended with substantial and comparatively lasting benefit, and until some better way is devised it will pay the user of a petrol engine to put in a dose of graphite from time to time, say, every day or two, even though it costs him a little time and trouble to do so. One user has recommended blowing the graphite into the cylinder through the sparking plug opening, first having placed the piston at the opposite end of the cylinder so as to leave as much as possible of the cylinder wall exposed to the flying particles. The oily interior of the cylinder catches some of the powder, and a noticeable improvement in the running of the motor is effected by this periodical treatment.

A better way to introduce the graphite is to unscrew the sparking plug and screw into its place a short nipple having a little hopper or funnel soldered to one end, and having an opening of, say, one-sixteenth of an inch; turn the flywheel until the piston is beginning the power stroke, and then put about half a thimbleful of graphite into the hopper and turn the flywheel forward half a revolution, and so suck the graphite into the cylinder in a form which may be compared with spray; if some of the graphite is inclined to stick to the side of the funnel, a few taps on the side of the nipple will dislodge and send it in with the rest. If the engine has an automatic inlet valve, the latter should be held closed if practicable, or, if possible, the opening admitting air to the carburettor should be closed; if neither of these things can be done, then most of the inlet can be closed by means of the throttle. Do not turn the flywheel far enough to open the exhaust valve, or some of the powder may be expelled through it. A quick and easy way to tell when the power cycle is about to begin is to set the ignition lever for late firing, switch on the current, and then turn the crank slowly, stopping when the trembler and the coil begins to buzz. This will indicate the beginning of the power stroke, if the adjustment is right.

Before putting graphite into the cylinder by either of the methods mentioned, the cylinder should be oiled freely, so that its interior will be in the best condition to catch and retain the powder. The use of graphite is not to take the place of the usual oil, but rather to act with it and add to the general lubrication, which it does very effectively. The periodical use of graphite exerts a beneficial influence on the cylinder and piston for a much longer time than would be expected, and its occasional use not only helps the engine for the time immediately following, but also helps out at times when the oiling device is either partially or wholly clogged, or when the operator forgets to turn on the oil; sometimes partially empty oil cups are overlooked, and not refilled; at other times the cups have an unaccountable way of feeding a hundred-mile supply of oil, while going only half that distance. Thus there are plenty of times when the cylinder stands in need of all the help which can be given it.

With some engines, or with some sparking plugs, or with certain locations of plugs, there is a possibility of trouble in using graphite from its short-circuiting the plugs, though probably this could be avoided by using a smaller quantity at a time; but it is worth while to use the graphite, even if some temporary inconvenience is occasioned thereby; the chances are that it will give no trouble, and if it should, the plug can be cleaned and less graphite used the next time. Those motorists who have not already done so should make a trial of graphite, in spite of the fact that the method of using it is far from an ideal one theoretically. They will not fail to notice that after using graphite a few times, other conditions being equal, the engine will run faster than it did before, proving that part of the power formerly employed in overcoming friction—and wearing out the engine—is now available for doing useful work instead of actual damage.—*The Horseless Age.*

[Should any readers of the *Journal* give the experiment outlined above a trial, we should be glad to hear from them regarding the results obtained.—Ed. *M.C.J.*]

CLUBS AND ASSOCIATIONS.

NORTHAMPTONSHIRE.

Major Payling presided at a meeting of the members of the Northamptonshire Automobile Club at the Great Northern Hotel, Peterborough, on Friday of last week. Amongst those present were Messrs. A. Adams, T. W. Southwell, F. W. Southwell, R. S. Parris, J. Montgomery, C. Godfrey, F. J. Goddard, F. W. Percival, R. Impey, F. J. Colls, R. Julyan, J. Rowe, F. J. Redhead, W. Walshaw, and E. H. M. Wood (the club secretary). It was intimated that an automobile club was being organised at Northampton, and that they wished to give it the county name. The present Northamptonshire Club consisted only of members residing in Peterborough and the surrounding district, and it was thought that the Club should be re-named. After some discussion Mr. T. W. Southwell proposed that the club should be called "The Peterborough and Counties Automobile Club." Mr. Godfrey seconded, and the matter will be further considered at a general meeting of the members on January 27th. It has been decided to hold the club's annual dinner at headquarters on January 19th, 1905.

After the meeting, Mr. J. Montgomery gave a lecture on "Coils and Accumulators." In the course of his remarks he mentioned that in batteries each cell gave off a pressure of 2·2 volts to make a 4 volt battery. It was a bad practice to make a connection between the two cells. They should be joined with a fuse wire in case of a wire becoming chafed and causing a short circuit. In the case of a car having a short circuit the wire would at once fuse; the current would, of course, cease to flow, and the motor would stop. The driver would look at the battery and notice that a "short" had done the mischief. The "short" having been found and put right, the fuse wire should be replaced, and he would then be able to start with undamaged accumulators. But if a "short" had taken place with a permanent connection it would not of necessity stop the motor, and might run another twenty miles. But the result would be disastrous. The "short" would discharge the battery very rapidly and most probably run it right down. It was a mistake to suppose that an accumulator actually stored electricity. It was made to give off electricity by being subject to a slow charge from an outside source. An accumulator might be damaged in many ways other than by violence. The quickest way to destroy a cell was to connect the terminal with a short piece of wire, causing a rapid current to flow. The plates would, however, be loosened. The only way to keep the plates intact was to never run the cell down below 3·8. Accumulators should be charged every week, even if they did not want it, as it would improve the plates. If the accumulator was going to remain idle for some time it should be left fully charged. The outside cells should be kept as dry as possible, and the terminals should be coated with vaseline or tallow candle, thus preventing the acid corroding and eating them away. The lecturer concluded a most instructive demonstration by a reference to the induction coil, which he said had not only made electric ignition possible, but a success. Votes of thanks to the lecturer and to Major Payling for presiding concluded a successful evening.

SHEFFIELD.

The gold medal, given by Mr. Jas. Barber, for the longest non-stop run made by a member of the car section has been awarded to Mr. Ben Hind, who covered 172 miles in 9 hours 55 minutes in his 9-h.p. Clement-Talbot. The gold medal given by Mr. J. T. Thompson for the longest non-stop run made by a member on a motor-cycle has been awarded to Mr. A. T. Dewhirst, who covered 50½ miles without stopping on his motor-bicycle.

The committee have received an intimation from the Chief Constable respecting the driving of cars at excessive speeds within the borough boundary, and they hope that members will exercise every care, having regard to the exigencies of traffic, and by so doing keep up the *entente cordiale* which has hitherto existed between the authorities and motorists in this district.

A run to Ollerton has been arranged for Boxing Day, meeting opposite the Town Hall, Surrey Street, at 10.30 a.m.

MANCHESTER.

Mr. Frederic Smith, the chairman of the Manchester Automobile Club, presided over the third house dinner of the Manchester Club at the Midland Hotel. About sixty members and friends were present. The dinner was followed by the first smoking concert of the winter session. Mr. W. E. Rowcliffe arranged an excellent programme, and was fortunate in obtaining the assistance of several first-class artistes, so that the concert was a great success.

A Heavy Load. [*Motor Age.*

Digitized by Google

VICTORIA (AUSTRALIA).

THE opening run of the 1904-5 season of the Automobile Club of Victoria (Australia) was held on Saturday, November 5th. The meet was at Princes' Bridge, Melbourne, and the route taken was around the Albert Park Lagoon, Beaconsfield Parade, and thence to Aspendale Park *via* Cheltenham and Mordialloc. Amongst those present were Mr. T. Rand, vice-president (16-h.p. Decauville), Mr. W. H. Felstead (10-h.p. Argyll), Mr. Tarrant (10-h.p. Argyll), Mr. W. J. Proctor (12-h.p. De Dion), Mr. Harry Maddox (who led the way on a 6-h.p. De Dion), Mr. G. Irish (8-h.p. Talbot), Mr. W. C. Knight (6-h.p. De Dion) Mr. Syd Day (8-h.p. De Dion), Messrs. J. Moffat, G. Moffat, R. Moffat, F. B. Roche, all on 6-h.p. De Dions; Messrs. S. Darby (16-h.p. Rambler), F. Bennett (7-h.p. Rambler), H. Darby (7-h.p. Rambler), T. Rollasson (7-h.p. Swift) J. Coleman (7-h.p. Swift), W. Warden (10-h.p. Oldsmobile), H. Walls (10-h.p. Oldsmobile), J. Davidson (10-h.p. Oldsmobile), Dr. W. S. Grimwade (5-h.p. Hun berette), J. Wallace (12-h.p. Benz), E. Beauchamp and C. Mayman (7-h.p. Beauchamp), Gerald Buckley (9-h.p. De Dion), etc., etc. Afternoon tea was enjoyed at "The Chalet," and after spending a pleasant two hours there the party returned to Melbourne. Whilst going down Mr. G. Buckley's car turned a complete somersault, pinning him by one leg to the ground. He was at once placed under medical care and taken home in one of the cars, where he is likely to remain for at least a couple of weeks.

The club arranged a three days' run, starting from the club rooms, Collins Street, Melbourne, at 2·30 p.m. on November 12th, returning again at 6 p.m. on Monday, the 14th. The weather throughout was simply perfect; the roads in some places simply horrible. The road chosen was *via* Rew, Box Hill, Lilydale, Healesville, Fernshawe, Narbeahong to Marysville, the return being *via* Healesville, Yarra Glen, Christmas Hills, Kangaroo Grounds, Eltham and Heidelberg. Some of the hills in the mountainous district were from one to three miles in length and grades of one in six and one in seven were plentiful. Twelve cars started, and all got through and returned within a few minutes of each other, with nothing more serious than tyre troubles and a little boiling water. Several ladies were included in the party, and altogether the outing was one of the most enjoyable held in connection with the club.

IMPORTS OF AUTOMOBILES.

BELOW we publish our monthly official list of the imports of motor-cars, motor-cycles, and the parts thereof, into the United Kingdom during the month of October, 1904:—

FRANCE.

MESSRS. JOHN LAWMAN AND COMPANY, of New Kent Road, S.E., send us a price list of their flexible metallic tubing of which they are making a speciality. The tubing is stated to be unaffected by heat and cold and to retain its flexibility at all temperatures.

TO CORRESPONDENTS.

All communications intended for insertion in this Journal or relating to Editorial matters should be addressed to THE EDITORIAL DEPARTMENT, MOTOR-CAR JOURNAL, *39 and 40, Shoe Lane, London, E.C., and must be written on one side of the paper only. Letters must in all cases be accompanied by the name and address of the writer, as no notice will be taken of anonymous communications.*

The Editors cannot undertake to return MSS. or drawings, although every effort will be made to do so in the case of rejected communications. Where such are regarded as of value, correspondents are requested to retain copies.

To insure insertion communications and contributions must be in the Editor's hands by Tuesday forenoon of the week in which the same are intended to appear. Disappointment may be caused by non-compliance with this rule, and to avoid this earlier receipt, if possible, is necessary.

The Editors do not hold themselves responsible for the opinions expressed by their correspondents, or for statements and facts which do not appear in the editorial columns.

The Editors and Publishers beg also to state that they will accept no responsibility for unsolicited contributions, even if used, unless payment for same is directly specified in forwarding, and the terms arranged before publication.

Published Weekly by CORDINGLEY & CO., 39 & 40, Shoe Lane, London, E.C.

COMMENTS.

MOTORISTS have closed a year which was, on the whole, delightful. July and August were glorious months that enabled them to taste the joys of our English scenery in a way that the weather had previously prevented. Hundreds of motorists explored the out-of-the-way corners of their native land which had hitherto been unknown; they studied geography on the spot, and realised that, however enticing may be the beauties of the Continent, our own little island has many wondrous scenes to reveal if the opportunity be given to the tourist to reach them. The automobile has made this possible. And the automobile need not be of a great horse-power, for even the motor-bicycle can be made a means of pleasure, especially when two or more are utilised in a family. Mr. and Mrs. Kennard, famous in the hunting field and in the world of books, are examples of motorists who despise not the little "bike," but who, on the contrary, have pleasure in its use.

◆ ◆ ◆

The Tri-car.

AS an unit, the motor-bicycle may be regarded as a solitary, unsociable sort of machine—fit only for young men fond of being alone or of rushing about the country at a speed of, say, the legal limit. Mr. and Mrs. Kennard could, however, testify to its value as an automobile which extends the range of social friendship, and adds to the pleasures of the country. The fore-carriage, or the sociable—or the latest development, the tri-car—is a step in advance, and have each their delights, and we know the secretary of an automobile club who prefers his miniature car to any of high degree. It goes well on the flat and romps up-hill in a manner "almost Japanese." We know a man who recently toured far and wide in Yorkshire on such a vehicle. On the broad Yorkshire acres he had found delights which, to one hitherto only familiar with Surrey, were pleasant in their novelty.

◆ ◆ ◆

Motor-Wagon Road Rules.

A DRIVER employed by the Hercules Motor-wagon Company was summoned before the Manchester city justices for not keeping a motor-wagon, of which he was in charge, on the left, or near, side of the road while passing along Dickenson Road about a fortnight ago. The Act of Parliament, it was stated, makes it the duty of the driver in all cases to keep a motor-wagon near the kerbstone, and he is required not to deviate from the near side of the road, except in case of actual necessity and for sufficient reason. On the occasion referred to an electric car was passing along Dickenson Road, and the defendant with his wagon was in front of it near the junction of that road with Stockport Road. The car driver said that his passage was obstructed on account of the defendant not keeping near to the kerbstone on his left side. The defence was that there was ice on the roadway, and that for the motor-wagon to have approached any nearer to the kerb would have been dangerous. The magistrates held that there was sufficient justification for the "deviation" of the motor-wagon, and they intimated that the summons would be dismissed. They were of opinion that the charge should have been one of obstruction. Mr. W. E. Rowcliffe appeared for the defendant.

◆ ◆ ◆

Motor 'Buses v. Tram-Cars.

AT the Wardmote for Bassishaw, Sir Alfred Newton, the presiding alderman, made reference to tramways in the City of London, and said that in his judgment the time was rapidly approaching when fixed tram-rails should be abandoned, and motor-'buses should take their places in crowded thoroughfares. This is a view that is steadily forcing itself upon the minds of all who have given any study to the problem of locomotion in our large towns and cities. Motor-'buses can be profitably employed on minor routes where tram-cars could never find a profit. They do not require a specially laid track, and have the advantage of being divertible from routes which are likely, after some experience, to prove unremunerative.

◆ ◆ ◆

Coachmen as Chauffeurs.

IN the course of a lecture on motor-cars the other evening in the Coachmen's Club, Dundee, Mr. Thomas Shaw compared the automobile with the horse, and pointed out the improvements that had been made on automobiles during the last six years. He said chauffeurs did not require to be engineers, but men with a good general knowledge of traffic. In his opinion, coachmen made the best motor drivers. This is a point upon which owners and mechanicians have shown little agreement in the past. There is, however, a general opinion that the man who has had engineering experience is not always so careful of the appearance of the carriage work as is the man whose work has been mainly in that direction. Chauffeurs, by taking a pride in the way they place their vehicles upon the road, can do much to allay the prejudice against the "unsightly motor," and they must realise that appearance counts for a great deal in that connection.

◆ ◆ ◆

Police Traps.

OWING to the weather, motorists have been indoor folk this Christmas, and comparatively few cars have been seen on the roads. Where the fogs have cleared other dangers have lurked, and a police trap on the Bath road has resulted in fines amounting to £50 being inflicted at the Brentford Police Court. When northern motorists are congratulating themselves on the absence of such persecution, it is significant that the south is still subject to these methods. Hence the feeling that has been excited against the police in many counties below the Trent.

◆ ◆ ◆

The Danger of Dogs.

THE dangers that motorists run when dogs jump about the roadway in proximity to a car has been exemplified in a very sad way at Derby. Dr. Henderson Pounds, a well-known surgeon, has just died there as the result of an accident sustained whilst motoring. A dog ran under his car, deflected

Digitized by Google

the steering gear, and threw him into a hedge, inflicting injuries which have proved fatal. Owners of dogs who are inclined to regard motorists as foes to their pets should remember that cases like this give motorists real cause to be alarmed when dogs rush out into the roadway in a menacing fashion.

◆ ◆ ◆

A Scottish Worthy.

MOTORISTS will join in congratulations to Lord Kingsburgh, who entered his sixty-ninth year on Tuesday. Those who participated in the historic 1,000-mile trial will remember the keen interest the Lord Justice-Clerk of Scotland took in that event, and the great support he has always given the automobile movement. Sir J. H. A. Macdonald has had a busy and varied life, having sat in Parliament and having been a member of many important Commissions. An enthusiast for the Volunteer movement, he is the Honorary Colonel of the Motor Volunteer Corps. Several inventions relating to the saving of life have been introduced by him, and his persistent advocacy of the post-card led to its adoption in the British postal service.

◆ ◆ ◆

A Street Danger Signal.

RED equilateral triangles are likely to become familiar objects in the landscape, these being the means sanctioned by the Local Government Board for warning motorists of dangerous corners, cross roads, or precipitous places. The sides of the triangle have to be eighteen inches in length, and some idea of the appearance of such sign-posts can be gleaned from the accompanying photograph, taken at Beckenham. There a dangerous corner is now indicated in the official manner with the sign-post as shown. This has been supplemented by the signal being also painted on the glass of the street lamp, so that it can be seen by night or day, a wise innovation.

◆ ◆ ◆

The Pedrail.

A PRACTICAL demonstration of the capabilities of the pedrail tractor, Mr. Diplock's attempt to solve the problem of heavy-weight haulage, was made last week in the clearing-yard of the Prince's Dock, Liverpool. Assembled to witness the working of the machine were some of the leading business men and engineering experts of the city, including members of the Liverpool City Council and their engineer, Mr. J. A. Brodie; members of the Mersey Docks and Harbour Board, with Mr. Lyster, their engineer, and others. After the demonstration Professor Hele-Shaw said that he regarded the invention as the first successful attempt to design an engine to carry its own railway with it. The inventor pointed out that the machine had been severely tested in actual working and by a trial run from Lincoln to London over very bad and soft ground. The present machine had an average speed of four or five miles an hour, and he was now designing one to average eight. He saw no difficulty whatever in making certain adjustments which would render feasible a speed of fifteen or twenty miles an hour, and looked to see the day when tramcars would be fitted so that they would run along the road without any other form of rails than the self-contained rail within the mechanism of the pedrail itself. Next month, at the request of the War Office, an attempt will be made to show what the machine is capable of doing in the way of hauling heavy loads over soft ground by pulling a big gun up the Long Valley at Aldershot.

◆ ◆ ◆

The Education of J.P.'s.

LOOKING back on the past year, motorists have little to be thankful for — so far as the administration of the law is concerned. Justices do not seem to have become less prejudiced, and there is still need for education in automobile matters among those who sit in judgment on county benches. It might be well if, during the coming year, a complete and systematic propaganda was undertaken among J.P.'s with a view to convincing them as to the reliability of the modern motor-car and the control which the driver possesses over its mechanism. Where county or local clubs exist, they should take up the idea, and, dividing the lists of magistrates among their members, make certain that none escape from an invitation for a trip by motor-car. That would give favourable opportunity for explanations on many points connected with traffic that are at present obscure to the average magistrate. We feel convinced that such a plan, generally adopted, would have very agreeable results.

◆ ◆ ◆

A National Undertaking.

WHERE local organisations are non-existent, the A.C.G.B.I. might take up the work. It has members throughout the country, and not a county is without its quota of motorists who, if approached, would be willing to assist by allowing magistrates to take trips by cars, and so complete the universal plan advocated. In the early days of the movement such demonstrations before county and other councillors had a softening effect on opponents; it is about time the idea was extended, so that the work of education may have a continuity which, in time, will effect a great change in public opinion. Now that clubs are making arrangements for their open-air doings in 1905 we trust the plan of combining the education of opponents with the pleasure of converts will be widely followed. In this way not only will the progress of automobilism be advanced, but the prosperity of the trade will be increased.

◆ ◆ ◆

The Dangers of the Road.

WHAT has been heralded in the Press as a "Dublin motor fatality" has passed the ordeal of the coroner's inquiry and the magistrate's court with a verdict of acquittal against the motorist in each instance. Miss Perry, who is a well-known motorist in the Irish capital, was proceeding slowly along Baggot Street, Dublin, when a lady about seventy years of age, and with sight that was dim, attempting to cross the roadway was knocked down. She died from the injuries received. The coroner's jury returned a verdict that "the occurrence was purely accidental and could not have been avoided by the driver of the motor-car." The magistrate's view was coincident with that opinion, and the public have had another warning as to the necessity for exercising care when crossing busy streets. Even when the traffic is of the slow moving kind caution and prudence should prevail.

The 1905 Exhibition.

ALREADY interest in motoring circles is being aroused in the exhibition programme for the coming year, and the recurrence of the annual display at the Agricultural Hall, London, is being commented upon by the general Press in terms that admit of no doubt as to the concern of the public in the latest development of automobilism. Several types of vehicles—English as well as foreign—which cannot possibly be got ready for the earlier displays will be seen at the March show, and those who are inclined to believe that the selling season will not really begin till the spring are naturally booking spaces. The last month has seen a notable accession of exhibitors in the light car section. The heavy vehicle department will, as we have already stated, be the most complete display of the kind ever seen.

◆ ◆ ◆

Ripon Wants Prohibition.

IN Yorkshire several attempts have been made to reduce the speed of motor vehicles, and, in fact, to prohibit them altogether from several roads. The latest authority to consider the matter is the Rural Council of Ripon. This august body appointed a committee to examine the matter in all its relationships, and in the end it has been resolved to schedule some of the roads with a view to the Local Government Board prohibiting automobile traffic thereon. These are the roads between High and Low Grantley; Grantley to Thwaite; Warren Lane to Laverton; and Dishforth to Copt Howick. No recommendations are to be made with regard to the restricted speed of ten miles an hour, but the idea of prohibition is sufficiently alarming to cause the hope that the Yorkshire Club will be characteristically alert in safeguarding the national interest of motorists.

Fording the Stream—A Reminiscence of Summer.

◆ ◆ ◆

Subsidised Services.

WITH a view to the advancement of the public interest, the Government of Italy is proposing to grant subsidies to local bodies that are prepared to establish motor-car services—provided that neither tramways nor railways already exist in such districts. These subsidies are likely to be at the maximum rate of £20 a kilometre for a service for passengers and goods traffic; £16 where only passengers are served, and £8 where only goods are conveyed. This is interesting as showing how international is the area of motor-car development. Whilst on the Continent the State seems anxious to help such works of utility, private men of public spirit are rendering almost similar service in South Africa, and owing to unsatisfactory railway arrangements certain Paarl financiers have been approached to run a motor service between Wellington and Capetown, to which they have consented, provided a sufficient number guarantee to make use of the service for a certain period.

◆ ◆ ◆

Dust in 1800.

THE dust, like the poor, is always with us. Modern men must not imagine that the clouds of dust sometimes seen on main roads are the minatory churnings of the motor-car. Even De Quincey found the dust a nuisance long before Hancock's daily journeyings from one end of London to the other. It was in May, 1800, that the opium eater first saw the great Metropolis. "We," he wrote, "were in an open carriage, and, chiefly to avoid the dust, we approached London by rural lanes, where any such could be found, or, at least, along bye-roads, quiet and shady, collateral to the main roads." That was more than a hundred years ago.

◆ ◆ ◆

A Farmers' Resolution.

THE members of the Taunton and West Somerset Farmers' Club are a delightful set of fellows, with no partiality for automobiles, and at a meeting just held have passed a resolution of a very meaningless description, which doubtless is regarded locally as having driven motor-cars off the roads. Mr. S. Kidner was the proposer of the resolution, which reads as follows:—"That the whole question of the public rights and safety be re-considered as regards motor traffic on public roads." What effect this will have we will not venture to imagine, but Mr. Kidner's oration in support of his motion was almost picturesque. The old-time governess cart was trotted out; the carriage driven by a lady was gallantly drawn, and pathos was introduced in the shape of sweet innocent children having to scuttle from their road-playground or else be mangled, maimed, or murdered by a scorching motor-car. The retort that motor-cars had come to stay was rejected as a mere "canting cry," and after such a flood of vapid eloquence the farmers resolved that the question should be re-considered, but omitted to say by whom.

◆ ◆ ◆

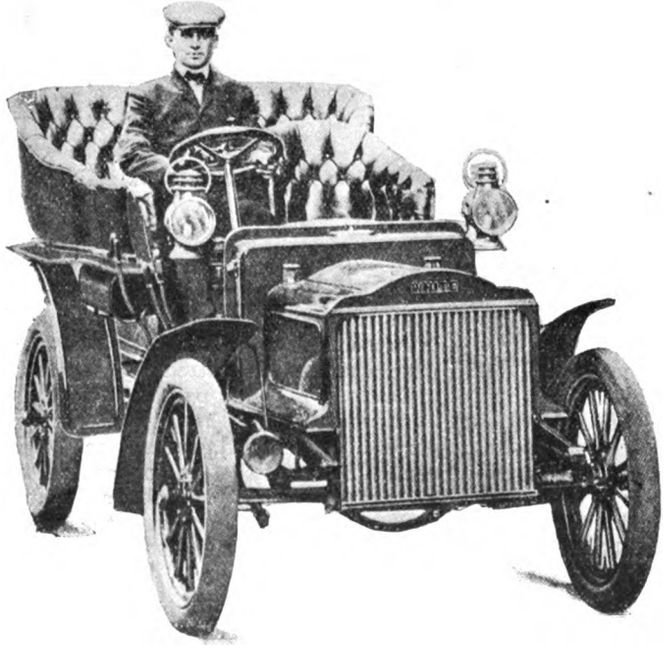
Domesticating Speed.

LADY HENRY SOMERSET has given us a new phrase. The motor-car, she says, has "domesticated speed," and has "added a joy to life which is a distinct asset to existence." With both of these assertions we agree, and there is no doubt that the coming of the car is quickening the movement of traffic in all the main streets. While it is true that progress is always restricted to the rate pursued by the slowest moving vehicles, the growing irritation at their lack of rapid motion is tending towards speedier movement. We are becoming

Digitized by Google

accustomed to more accelerated travel on the roads, and Lady Somerset's saying that the motor-car has "domesticated speed" is not only neat but has the advantage of being true.

◆ ◆ ◆



The Lohner-Porsche Electric Vehicle used by the Fire Brigade of Frankfort-am-Main.

◆ ◆ ◆

See to the Brakes.

It is unfortunate that some motorists venture out with their brakes in bad order, but such is the case, and about the worst possible thing that could happen to a motorist is his car colliding with anything owing to defective brakes. Motor-cars have the reputation of being able to pull up in a few yards; surely it is better that they should live up to it. Always look after the brakes, and if one is faulty do not go out till it is repaired. Some motorists put resin on their band brakes to ensure a good grip, but it is not an advisable practice, as it is detrimental to the brake. A really good brake does not need it; all that is required is a little adjustment from time to time.

The New White Steam Car, with Mr. Rollin White, its Designer, at the Wheel.

◆ ◆ ◆

Delhi to Bombay.

The Reliability Trials from Delhi to Bombay began this week, no fewer than thirty motor vehicles actually starting in the contest. The first day's run was to Agra, a distance of 130 miles from Delhi, and English motorists were delighted with the condition of the roads. Several non-stop runs were reported, h› chief incidents being a few tyres damaged by the nails from bullock shoes. Mr. Basil Johnson on a Napier arrived first at Agra and was equally prominent on the second day's run to Gwalior. The event should do much to popularise the motor-car in the Indian Dependency, and has certainly provided the natives with a new sensation.

◆ ◆ ◆

A Club for Ceylon.

Not only in India, but in Ceylon as well, interest in motoring matters increases continuously. The Automobile Club, which has just been formed with headquarters at Colombo, has already seventy-seven members. Mr. Harold North is the hon. secretary for the organisation, which holds its meetings at the Queen's Hotel, Colombo. We understand one of the objects it has in view is to secure direct relations with some English houses dealing in motor accessories and the like.

27-33, Charing Cross Road, W.C.

Letters sent to *The Motor-Car Journal* next week should be addressed to 39-40, Shoe Lane, E.C. After the 7th prox., however, the offices will be removed to 27-33, Charing Cross Road, London, W.C., where we shall be in the centre of the London motor industry—a matter of convenience to advertisers and subscribers in the Metropolis. We make this early announcement for the benefit of our correspondents in Europe and the United States, who are asked to make prompt note of the new address of the *Motor-Car Journal*.

A sports meeting is being arranged by the Auckland (N. Z.) Automobile Association.

An automobile service for the carriage of the mails between Lille-le-Guillaume and Mayenne, France, is shortly to be inaugurated.

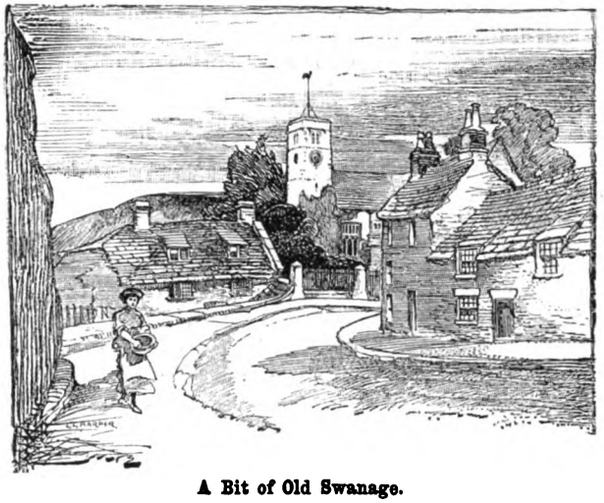
It is announced that instead of the Nice automobile week taking place in February, as originally determined, it is to be postponed until the latter part of April.

A syndicate has been formed to establish a public motor-car service between Northeim and Echte, Germany. The mails between the two places are also to be carried. A service has also been inaugurated between Traunstein and Chiemsee, Bavaria.

It has been decided that the Spa automobile week shall be held from the 3rd to the 10th of September next. The provisional programme comprises a balloon chase, a touring car competition, the Spa-Malchamps hill-climbing test, and a flower fete.

Messrs. Wallis and Watson, of Leeds, inform us that they have purchased the *chassis* of the new 20–24-h.p. Argyll shown at the Paris *Salon*, and that they have taken up the sole agency for the Argyll cars for Leeds, Knaresboro', York, and intervening districts.

Messrs. Muratti, Sons and Co., Ltd., have agreed to present the Ulster Centre of the Motor Cycle Union of Ireland with a massive silver cup, of unique design, as a trophy for a motor-cycle contest to be decided under the auspices of the Motor Union next year. The cup is to become the property of the person who wins it three times. The contest will take place about the end of July next year, but the other details of the event have to be decided.



The new world's motor-bicycle records established by Anzani, referred to in a recent issue of the *Journal*, have not been allowed to stand long, for the other day, on the Parc des Princes track, in Paris, Giupponé, on a Peugeot machine, set up new record times both for the hour and for the 100 kilometres. Within 60 minutes he rode a distance of no less than 56 4-5th miles, and completed the 100 kilometres (62½ miles) in 1 hour 6 min. 36 2-5th sec.

THE HARDY COUNTRY.

ACCORDING to the fashionable bookseller motoring has invaded his profits and whirled people from the library to the country. They no longer find time for the popular novel and have no delight in the *belles lettres*. The fascination of a rush through a dozen counties, with glimpses of ancient churches peering through the breaks in the lines of trees, takes the modern man from his books; and the bookseller has become a dolorous person delighting only in reminiscences of the good old days of not so very long ago. He is a person without hope for the future, when the modern craze, widening and developing, will destroy a taste for reading and he will have to enter the automobile business for means of sustenance.

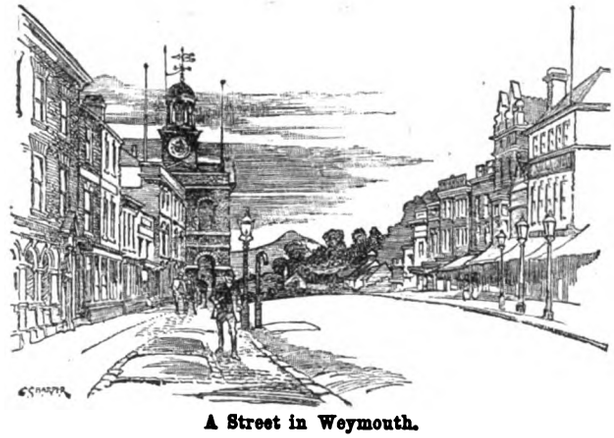
If occasional paragraphs, thoughtlessly written for popular prints, can be credited, such is the outlook of the bookseller. True the

A Bit of Old Swanage.

motor-car has entered into rivalry with the bookshelf; but it has also opened new avenues of literature which were formerly restricted. And in the outpourings of guides and road histories is evidence of a supply to meet the demands, to a large degree, of the motoring section of the community. We study literature in pilgrimages; a glance at an early English church raises a thirst for more knowledge of architecture; scampering across hills and dales whets the desire for closer study of nature, and the newer life led in hotels has opened up definite study of social questions that were of transient interest before. So that in bookselling, as in other things, the "demand" may have been diverted into channels where the tide has not yet risen, but it is in existence, and in due course will be met by modern writers. As Thackeray wrote in his introduction to the "Book of Snobs," the Occasion never arises which does not bring the Man to deal with it.

The series of literary pilgrimages which Messrs. A. and C. Black are publishing is an instance in proof. Circling round authors like Scott, Dickens and Burns are pages of pleasant history and modern happenings. They are more than guides to places teeming with recollections of bookish friends; they are inciting companions to the man with a car, whose trips are likely to be more enjoyably spent with such volumes as signposts than merely touring with his fancy as an alluring mirage.

Literary landmarks of the Wessex novels of Mr. Thomas Hardy are the pegs whereon Mr. C. G. Harper, whose "Ingoldsby Country" opened up the county of Kent in quite a new way, hangs three hundred pages of writing that should be the preliminary stage to the reading of the novels themselves. Outside that part of the country so familiar to Mr. Hardy who knows that "Melchester" is Salisbury, that "Casterbridge" is Dorchester, that "Shottsford Forum" is Blandford, that "Knollsea" is Swanage, that "Anglebury" is Wareham, and so on? Realise these locations and interest is intensified; visit the places and the novels will be read, not scanned.



We know of no better book in this category than Mr. C. G. Harper's "The Hardy Country," which he introduces as follows:—

"In the literary partition of England, wherein the pilgrim may discover tracts definitely and indissolubly dedicated to Dickens, to Tennyson, to Ingoldsby, and many another, no province has been so thoroughly annexed or so effectively occupied as that associated with the Wessex novels written by Mr. Thomas Hardy. He holds Wessex in fee-simple, to the exclusion of all others; and so richly topographical are all those romances that, long ere sketch-maps showing his literary occupancy of it were prepared and published in the uniform edition of his works, there were those to whom the identity of most of his scenes offered no manner of doubt. By the circumstances of birth and of lifelong residence the "Wessex" of the novels has come to denote chiefly his native county of Dorset, and in especial the neighbourhood of Dorchester, the county town; but Mr. Hardy was early an expansionist, and his outposts were long ago thrown forward, to at last make his Wessex in the domain of letters almost coterminous with that ancient kingdom of Saxon times, which included all England south of the Thames and west of Sussex, with the exception of Cornwall."

Mr. Harper is no mere litterateur, gliding from one subject to another with butterfly lightness, but he is an observer, and has gone behind the cobwalls and probed deeper than the thatch into the ways and customs of the people with whom he has spent many pleasant days. We have reminiscences of the past—kings and battles are presented with a wealth of historical lore redolent of Hume and Macaulay; but there is a keen insight into the present ordinary life of the Dorsetshire peasant, as the following excerpt will show:—

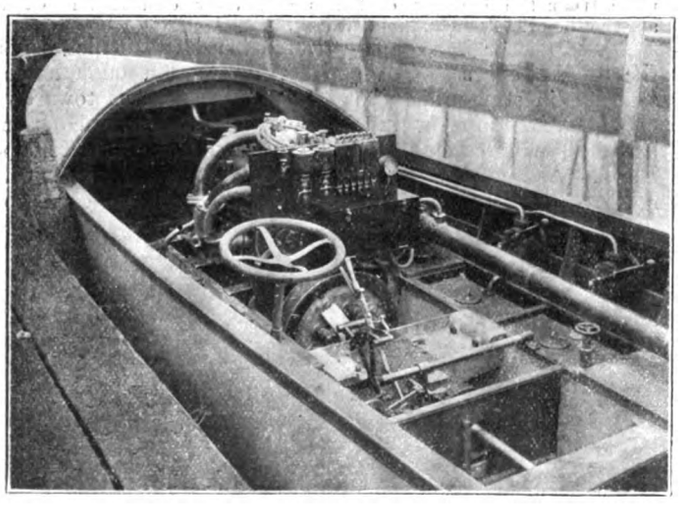
"The old country life still closely encircles the county town, and on market-days takes the place by storm; so that when, by midday, most of the carriers from a ten or fifteen miles radius have deposited their country folk, and the farmers have come in on horseback, or driving, or perhaps by train, the slighter forms, less ruddy faces, and more urban dress of the townsfolk are lost amid the great army of occupation that from farms, cottages, dairies, and sheep-pastures has for the rest of the day taken possession of the streets. The talk is all of the goodness or badness of the hay crop, the prospects of the harvest, how swedes are doing, and the condition of cows, sheep, and pigs; or, if it be on toward autumn, when the hiring of farm-labourers, shepherds, and rural servants in general for the next twelve months is the engrossing topic, then the scarcity of hands and their extravagant demands are the themes of much animated talk."

The author is as facile with his brush as with his pen, and the illustrations scattered about the volume, though having a sameness in style which grows almost reminiscent towards the end, add to the interest of the volume, as will be imagined from the sketches we reproduce by favour of the publishers, Messrs. A. and C. Black. As hinted in the first chapter, the travels are not wholly restricted to Dorsetshire, and the work will be welcome to all

A Street in Weymouth.

who travel westward from London. Mr. Harper delights in contrasts, and some of the most effective writing brings monotony and variety or old and new together in pleasant fashion, as witness our last quotation:—

"The juxtaposition of a place so new as Bournemouth with one so ancient as Poole is a piquant circumstance. When Bournemouth rose, not like Britannia, from the azure main, but from beside it, there was a considerable interval of open country between the hoary seaport and the mint-new pleasure-town. That interval has now shrunk to vanishing-point; for, what with Bournemouth's expansion, growing Parkstone's position midway, and Poole's own attempt to sprout in an eastwardly



Digitized by Google

direction, to meet those manifestations, the green country has been abolished beneath an irruption of bricks and mortar. Poole, besides being ancient, has been a place to reckon with. Already, in 1220, when by a proclamation by Henry III. the ships of many ports were sealed up, Poole appeared among the number. In 1347 its contribution towards the siege of Calais was four ships and ninety-four men, and it was the base from which the English army in France was provisioned. Then in 1349 came that fourteenth century scourge, the Black Death, and Poole, among other towns, was almost depopulated, and lost the Parliamentary representation it had long enjoyed. But it made a good recovery, and in the time of Henry VI. regainedits parliamentary representation. Leland, writing of the place, describes it, two hundred years later, as 'a poore fisshar village, much increased with fair building and use of merchaundise of old tyme.' Poole, after the description was penned, continued to recover itself, and fully regained its lost prosperity.'

In closing this notice of the volume we are tempted to say that motoring and literature are likely to be closely associated in the future. Several writers have already contributed, both learnedly and lightly, to the automobile library that is steadily being formed, and, on the other hand, writers like Conan Doyle, Max Pemberton, Rudyard Kipling, and others have adopted the motor-car as a means of health and pleasure. Had Carlyle been a motorist, some of his more sombre chapters might never have been penned; had Browning ever known the motor-car the Pied Piper of Hamelin might have developed strangely; but we will not reflect long in that strain. Suffice it to say that automobilism is casting its spell over the world of books as well as over the face of the globe.

THE "NAPIER MINOR" MOTOR-BOAT.

SOME particulars of the Napier Minor motor-boat which won the 1904 race for the Harmsworth Cup, but which, under a protest, was awarded to France, may not be without interest. The accompanying picture clearly shows the engine, the steering wheel, clutch and control levers. As in a motor-car the motor is placed forward of the dashboard, which

in motor-launch parlance is termed the instrument board. The boat, which was built for Messrs. S. F. Edge, Limited, by Messrs. Saunders, of Goring-on-Thames, is 35 ft. long and 5 ft. beam. She is constructed on the Saunders sewn principle of cedar and mahogany, with oak beams. The hull is enamelled grey, and the decks are white, and ample accommodation has been provided for about fifteen passengers. The boat is divided into two portions, the fore part containing the machinery, consisting of a 53-m.p. 4-cylinder standard Napier marine motor. The steering and control apparatus are all regulated by one man, who is well protected by the whaleback. The after part of the boat contains a long cockpit, and is fitted with the usual cushions and grating, and has a hood to protect the passengers from rain or spray. The exhaust has been installed in such a manner that no heat emanates from the same, and the discharge is invisible and noiseless.

THE HORSE POWER OF PETROL MOTORS.

ONE of the most puzzling things to the intending purchaser of a motor-car is the apparently incomprehensible and arbitrary horse power ratings of petrol motors. He is shown a certain engine that is rated at 16-h.p., and in the next saleroom is shown one vastly larger in bulk but rated at the same power, while in still another an engine of obviously smaller outside dimensions than the first is stated to be of 20-h.p. Then, again, he is confronted with combinations such as 18-24-h.p., 30-35-h.p., etc. In each case the salesman has a plausible explanation, but as the various explanations do not agree, the purchaser is just as much, or even more, at sea than ever.

Some salesmen explain the 18-24-h.p. expression by saying that 18-h.p. is the French value and 24-h.p. the English. This impression is rather widespread, but that it is not correct is easily shown by the following figures, which may be useful to remember:—An English horse power is equal to 33,000 pounds raised one foot in one minute, or 550 foot-pounds per second. The French horse power (cheval-vapeur) is equal to 542·5 foot-pounds per second, or is ·9863 of an English horse power, or, one English horse power equals 1·0139 French "cheval-vapeur." It will, therefore, be seen that the horse power is larger than the "cheval-vapeur," but that the difference is only about 2 per cent. The French, however, use also the "poncelet" as a unit of power, which is 33 1-3 per cent. larger than the "cheval-vapeur," but as it is mainly used in scientific tests and seldom appears as the power rating of motors in makers' catalogues, there is little excuse for confusion. The "poncelet" is 100 kilogramme-metres per second; the "cheval-vapeur" is 75 kilogramme-metres per second, and the horse power is 76·04kilogramme-metres per second.

In attempting to devise a simple method of computing the approximate power of an engine for the use of the non-technical purchaser, one is at once confronted with the two radically different types of engines now on the market; namely, the horizontal engine of slow speed, and the vertical motor of one or more cylinders. As the latter type, if of average good design, will run as fast as 1,400 or 1,600 revolutions per minute, it may be taken roughly that they will develop one horse power for each ten cubic inches of piston displacement. For example, a four-cylinder engine, having cylinders of four inches bore and five inches stroke, might be figured roughly thus:—$4 \times 4 = 16$, 3-4 of $16 = 12$ = area of piston in square inches. Multiplying this by the stroke, 5 inches, gives 60 cubic inches as the piston displacement (it is 62·83 exactly). Dividing by 10 cubic inches per horse power and multiplying by 4, the number of cylinders, gives 24-h.p., which is very close to the actual horse power; in fact, it is close enough for all practical purposes. With the slow speed engines it is difficult to give even an approximate rule, as their "characteristic" curve of speed and power varies greatly. An approximately correct value may be obtained by allowing from 12 to 20 cubic inches per horse power, according to the speed that the engine is capable of. Thus, if the cylinder dimensions are known, any one can in a few minutes obtain a fairly accurate idea of the power of any given engine irrespective of its catalogue rating or the claims of the salesman.

While the above is true for the average engine under average conditions, yet many motors will, states our American contemporary "The Automobile," do much better because of better design and workmanship. Many engines are rated much below their maximum capacity for various reasons, one being that a low rating avoids disputes as to incapacity to develop the stated power. While it would be highly beneficial to the industry and convenient for the purchasing public for the manufacturers to adopt a uniform rule for rating petrol motors, yet it seems too much to hope for at present.

A MOTION for the purchase of a motor-car for the use of the Glamorgan county surveyor has been remitted back to the committee that proposed it by the County Council.

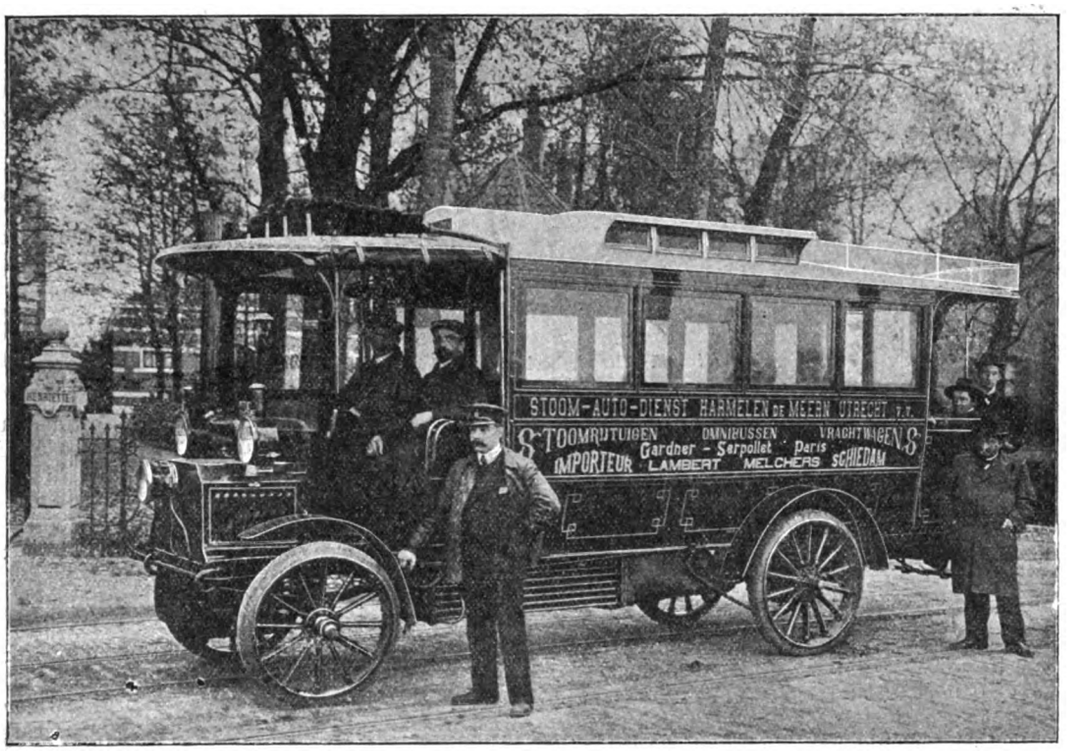
CONTINENTAL NOTES.



The Gordon Bennett Race.

A good deal of attention is just now being devoted to the question as to where the 1905 Gordon Bennett race is to be held. New circuits are being proposed daily, but no definite decision has been arrived at, although prospects seem in favour of what is known as the Circuit d'Auvergne, which is the one proposed by M. Michelin. If selected, however, the course will have to be modified at certain points, notably at Rochefort, where the turning forms such an acute angle that the cars would have to almost stop in order to negotiate the corner.

A Dutch Public Service.

A public automobile service has lately been inaugurated between Utrecht and Harmelen. The accompanying illustration depicts the type of vehicle being used; it is a 20-h.p. Serpollet "steamer," the *chassis* having been imported by Mr. Lambert Melchers, of Schiedam, and fitted with a Dutch-built body having accommodation for twenty-four passengers.

A Dutch Public Motor-Car Service. [*De Aut*

◆ ◆ ◆

The International Motor-Boat Congress.

An International Motor-Boat Congress was held in Paris last week, when the rules and regulations in regard to motor-boat races to come into force in 1906 were discussed. It was agreed that every possible scope should be accorded to builders of engines and hulls, and that there should be no restrictions capable of acting as a handicap against types of machinery or boats not now in common practice. Commencing from 1906, the classification of motor-boats will be made according to metrical dimensions. Length, it was decided, should be the sole rating of racing boats, no limit being imposed on engine power.

◆ ◆ ◆

An International Federation of Motor-Cycle Clubs.

A congress of representatives of the principal motor-cycle clubs of France, Germany, Belgium, Austria and Great Britain (Messrs. M. O'Gorman and Pennell representing the Auto-Cycle Club) was held in Paris last week, when it was resolved to form a Federation Internationale des Clubs Motocyclettistes. The leading club in each country is to appoint a delegate to attend the half-yearly meeting of the F.I.C.M., as the new body is to be known. It has been decided that the 1905 race for the International Motor-Bicycle Cup shall be held on May 14th next.

◆ ◆ ◆

The Paris Salon "Tombola."

Every visitor to the Paris Salon received a numbered ticket entitling him to participate in the "Tombola" or draw for the hundred or so prizes which are annually offered by various firms in connection with the Exhibition. The draw took place on Sunday evening; we have not space to give the whole list of prize-winning numbers, but, in case some English visitors hold lucky numbers we give the first three:—

			Winning No.
1.	...	a 10-h.p. Richard-Brasier Car ...	317586
2.	...	a Dufayel Piano ...	359243
3.	...	a Rheda Car Body ...	221589

◆ ◆ ◆

The De Caters Cup.

Baron de Caters announces the offer of a valuable cup for an international tourist car non-stop competition over a distance of 500 kilometres. Broadly speaking, the idea is that the cars shall be of the ordinary type as sold complete by the manufacturers, but it is proposed that a minimum weight shall be fixed, according to the *chassis*, for the body portion of the car. No detailed rules are at present laid down, it being thought best to take the views of all those who are interested in the matter before drawing up the conditions.

◆ ◆ ◆

A Much-copied Car.

The firm of Rochet-Schneider, of Lyons, occupies a unique position, as cars from its designs are being made under licence in Switzerland, Belgium, and Italy. Specimens of the vehicles turned out in each of these countries were on view at the *Salon*, the Swiss type being represented by Messrs. Martini and Company; the Belgian by La Société la Locomotrice, of Liege, and the Italian by La Fabbrica di Automobili Florentia, of Florence.

The Paris Motor-Car Exhibition—III.

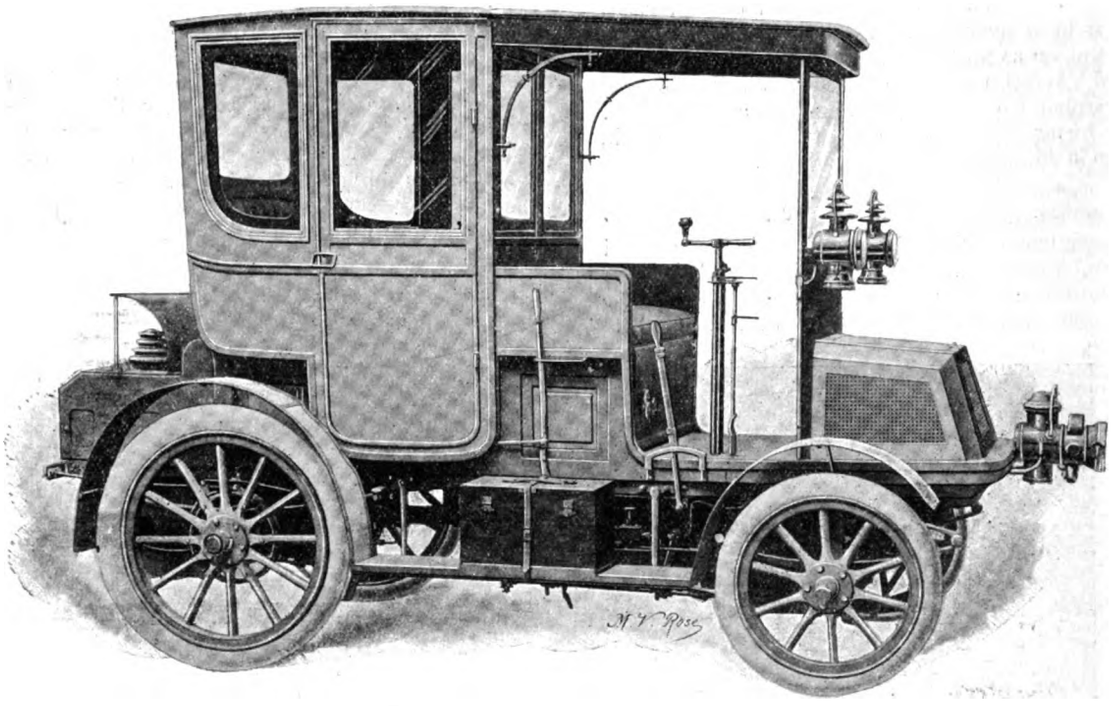

Fig. 42.—The Chaboche Steam Coupe.

THE seventh annual *Salon* in Paris was brought to a close on Sunday last, amidst a display of thousands of Bengal lights. Throughout the day the Grand Palais was invaded by a vast crowd of sightseers—a term we use advisedly, as it was impossible for anyone interested in the cars on view to get sufficiently near to give them close inspection. The final day was marked by a visit from M. Pelletan, the Minister of the French Navy.

M. CHABOCHE displayed several of his 12-h.p. and 20-h.p. steam cars with a double-cylinder vertical engine under the bonnet. The vehicles, which outwardly resemble petrol cars, are driven by means of a cardan shaft and bevel gear on to the rear live axle. The generator, which is located at the rear, has been improved in so far that should anything go wrong with either of the last two elements it may be readily disconnected without preventing the boiler from working. Any form of carriage body can be fitted to the *chassis*, Fig. 42, showing a four-seated coupe.

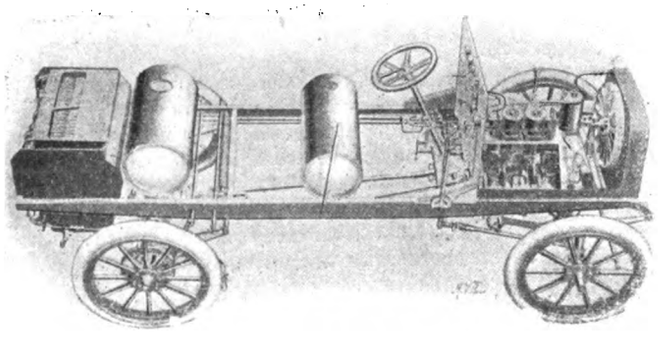

Fig. 43.—View of Chassis of Chaboche 20-h.p. Steam Car.

A novel pneumatic buffer for the springs of motor-cars was to be seen at the stand of Mr. LEONARD HARRIS. As will be seen from Fig. 44, it consists of two light metal saucer-shaped pieces, between which a rubber sphere is inserted. Within the latter is a rubber ball fitted with a valve, so that it may be inflated to any desired pressure. The buffers, which can be fitted to both the front and rear springs, are claimed to not only relieve the springs of all strain, but to take up fully half the shocks received by the tyres, so increasing the life of the latter and the general comfort of the vehicle.

MESSRS. DROUELLE AND COMPANY exhibited a number of electric cars which are being introduced into England by the Garcin-Renault Electric Cars and Accumulators, Limited. The *chassis* consists of a perfectly straight platform to which all the mechanical parts are attached, and upon which practically any form of body can be fitted. The motor is carried in the front end of the frame nearly over the front wheels. It is designed to run at speeds ranging from 300 to 750 revolutions per minute, and is capable of developing 14-h.p. The power is transmitted by means of a cardan shaft direct to the rear live axle, no gear whatever, except that for the differential, being necessary. The battery consists of forty-four cells, of a capacity sufficient to run the car about sixty miles over ordinary roads. The lever by which the speeds are operated is placed just below the steering-wheel. In addition to the electric brake there are two mechanical brakes, one acting on the cardan shaft and the other on the rear wheels.

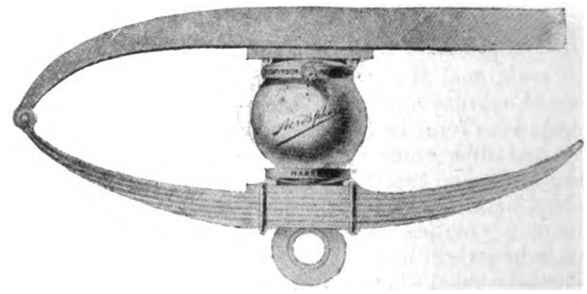

Fig. 44.—The "Aeros" Pneumatic Spring.

Digitized by Google

In addition to the 10-h.p. car, the new features of which have already been described in the *Journal*, LA SOCIETE DES AUTOMOBILES MOTOBLOC, of Bordeaux, represented in England by Messrs. Montague Hawnt and Co., are bringing out a 16-20-h.p. car with a four-cylinder vertical engine. The cylinders, which are 95 mm. diameter by 120 mm. stroke, are cast in two pairs. The valves are all mechanically actuated; the inlets are arranged

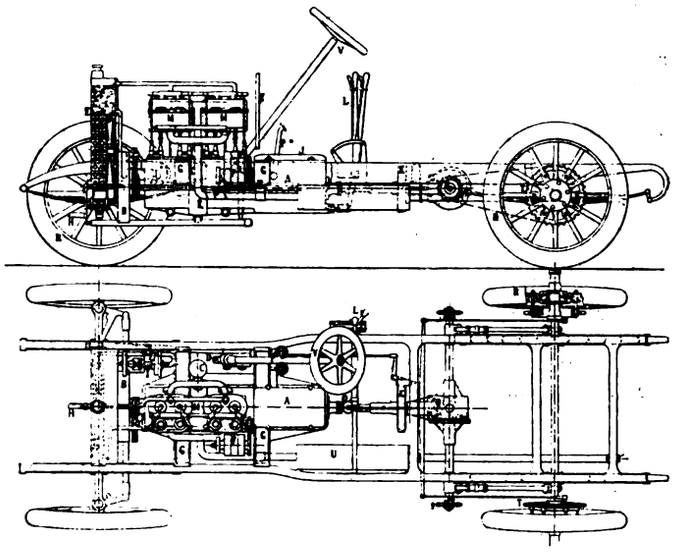

Fig. 45.—Elevation and Plan of Motobloc 16-20-h.p. Car.

in the cylinder heads and are provided with a simple, yet ingenious, variable lift device acted upon both by the governor and by a lever on the steering wheel, by means of which the speed of the engine can be regulated as desired. The water circulation is maintained by a friction-driven pump and a framed ribbed-pipe radiator. The ignition is by a chain-driven low-tension magneto. As in the 10-h.p. car the engine and change-speed gear box form a single "block," the gear box being practically an extension of the engine crank case. The latter encloses a small flywheel, while a second external one is mounted on the *forward* end of the crank shaft. The clutch, which is of relatively small diameter, is of the metal-to-metal type and is enclosed in

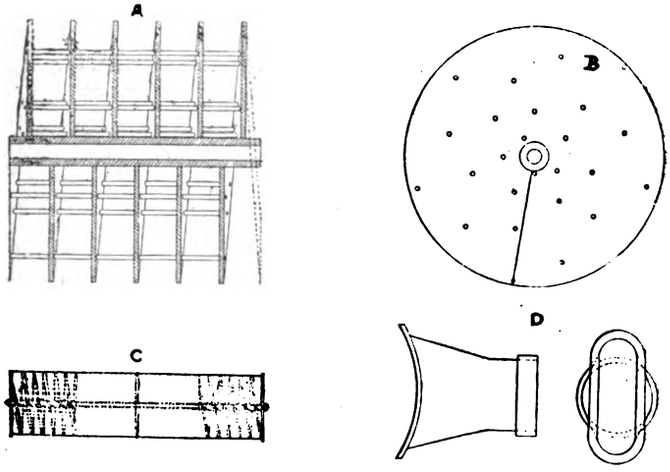

Fig. 46.—Details of "Stanley Perfect" Silencer.

the gear box. The change-speed gear is of the sliding type, giving three speeds forward and a reverse with direct drive on top. A universal joint is provided on the shaft between the gear-box and the differential shaft, side chains connecting the latter with the rear road wheels. It may be added that the frame of the car, which is of pressed steel, is sufficiently long to receive side-entrance bodies. The new 16-20-h.p. Motobloc is altogether an interesting model, and will, we understand, make its appearance in England at the Exhibition at the Agricultural Hall in March next.

The new firm of Messrs. GEORGES RICHARD AND CO. had on view an unfinished *chassis* of their 12-h.p. "Unic" car. The frame is of pressed steel fitted with a governed two-cylinder engine cast in one piece. The valves are all mechanically actuated, the exhaust valves being on the left side and the inlets on the right side of the motor. The valve caps are held in place by yokes, as is also the exhaust pipe casting. The carburettor is of a new self-regulating type. On the starting handle shaft a lever system is introduced, so that as the handle is engaged with the crank-shaft the ignition is automatically retarded; the ignition is by magneto. Three speeds and a reverse, with a direct drive on the top, are provided, the transmission being by a cardan shaft to a live axle. The latter is provided with special radius rods, these being held at their forward ends in spring supports. In addition to the long springs, the easy riding qualities of the vehicle are enhanced by the adoption of the Truffault anti-shock device.

M. P. RAMIER, of Puteaux, the French agent for the Stanley silencer, showed the latest form of this apparatus as devised by Mr. Stanley W. Andrews, whose object has been to provide a light and compact silencer, and which can be readily opened out for cleaning or repairs. Referring to Fig. 46, it will be observed from drawing C, which is a sectional view of the complete silencer, that a spiral path is first provided for the gas to pass through, after which it passes into an expansion chamber divided at its centre by a perforated wall; the gas then passes down a second spiral path exactly similar to the first, before escaping to the open air. Drawing D shows the construction of the special inlet connection. Its round end is, of course, of the

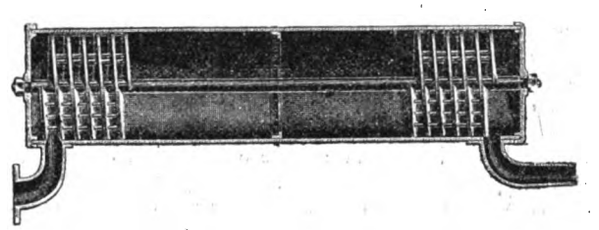

Fig. 47.—Section of "Stanley Perfect" Silencer.

same diameter as the exhaust pipe to which it is connected. The other end of the connection, although different in shape, still retains the same area as the exhaust pipe. Drawing A shows one of the spiral paths contained in the silencer. It is a single casting, having six or seven spiral turns about its centre. The gas in the passage through the spiral path becomes broken up. This is accomplished by means of rods passing through the spiral, as seen in A (as well as in B, which is an end view). These rods, although placed in different positions in the spiral, if brought together into one line, would completely close the space provided for the exhaust gases; but by placing the rods in various positions, taking great care that no two rods cover, the gas is allowed to pass, consequently being completely broken up. It is claimed that the silencer gives rise to no back pressure, and that the gas emerges into the air without any force or noise. The silencer is made in a variety of sizes suitable for engines of from 3-h.p. up to 30-h.p.

Messrs. BENZ AND CO. staged several of their Benz Parsifal cars, which for the 1905 season comprise five models—14-18-h.p., 18-22-h.p., 24-30-h.p., 35-40-h.p., and 60-h.p. All have four-cylinder engines with mechanically-operated inlet valves. The transmission can either be by side chains or by cardan shaft and live axle. The general design is unchanged, but a number of detail improvements have been introduced which render the vehicles well worthy of inspection. A somewhat novel form of petrol car was shown by M. GELAS, of Havre. It is of 12-h.p., and has the engine and transmission gear all supported by and driving the front wheels. No less than six speeds are provided, and a notable feature is the absence of pedals, the clutch and brake being actuated by the driver pulling the pivoted inclined steering column towards him.

One of the most interesting exhibits in the *Salon* was that of the COMPAGNIE DE L'INDUSTRIE ELECTRIQUE ET MECANIQUE of Geneva, which exhibited *chassis* of their 8-12-h.p. double-cylinder and 16-24-h.p. four-cylinder vehicles. As regards the engines themselves, the company appear to have reduced the detachability of the various parts almost to a fine art. By removing half a dozen nuts, for instance, the valve lifting rods can be removed, and by taking off the plate above the cam shaft this can be lifted out, the whole operation taking scarcely more

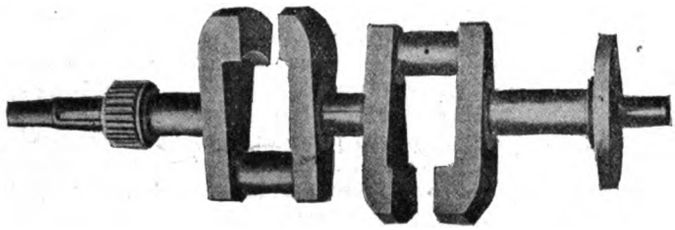

Fig. 48.—The C.I.E.M. Two-Throw Balanced Crank Shaft.

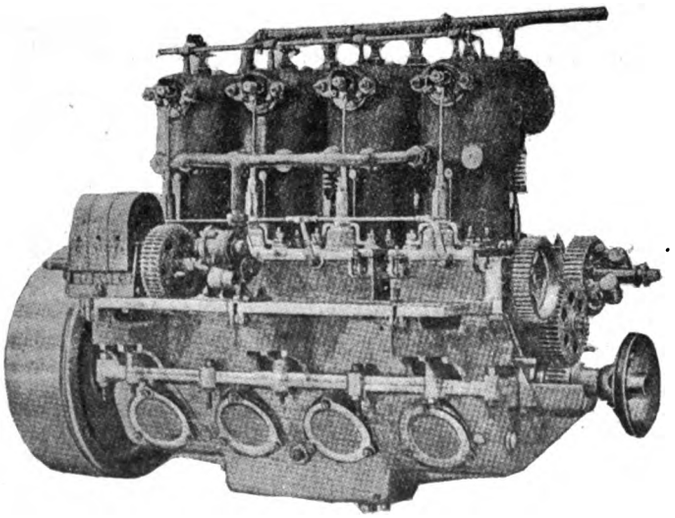
than a minute. The cylinders are cast separately, with the inlet and exhaust valves operated off one cam shaft, all parts being interchangeable. The ignition is by gear-driven magneto, the water-circulating pump being driven off the same shaft. Fig. 49 gives a view of the four-cylinder engine, and Fig. 48 depicts the crank shafts of the double-cylinder motor; from the latter it will be seen that the crank shaft is provided with special counterweights to give a perfect balance. The lubrication of the engine is ensured by pump oil circulation. The pump is driven off the magneto shaft, and sends oil to all the moving parts, where it has a constant circulation through the hollow crank and gear shafts, and is distributed through small holes into all the bearings. The frames of the cars are of pressed steel construction; three speeds and a reverse are provided. The propeller shaft has double cardan joints, and terminates at the gear box end in a sleeve forming part of a yoke, the ends of which are hinged on vertical pieces connected with the cross member supporting the gear box. The joints of the yoke are thus kept in perfect alignment with the ends of the radius rods so as to prevent any possibility of side strain on this part of the



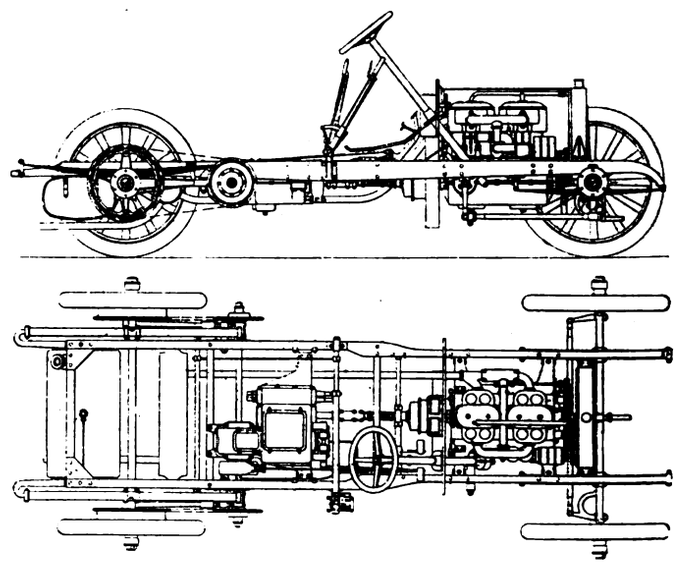


Fig. 49.—The C.I.E.M. 16-24-h.p. Four-Cylinder Motor.

mechanism. There are two rear axles, one of tubular form carrying the road wheels, and the other a live axle terminating in pinions gearing with internally toothed wheels bolted to the road wheels. One of the cars was fitted with a novel self-starting arrangement invented by M. Batault. This consists of a cylinder in which is a piston and a rack kept under tension by a spiral spring. The lower part of the cylinder is cut away to allow of the rack gearing with a toothed ring cut on the flywheel rim. At one end of the cylinder is a valve opened by a hand lever, which on being pushed forward brings the rack of the cylinder into mesh with the teeth on the flywheel. A charge of carbonic acid is at the same time admitted into the cylinder, which, expanding, drives the piston forward, giving half a turn to the engine through the flywheel. Immediately the motor starts the cylinder rises clear, a spring bringing the piston back to its former position. The carbonic acid is carried in a cylinder near the dashboard, the capacity being sufficient for 150 charges.

THE Fiat Company exhibited a *chassis* of their 1905 24-32-h.p. car, which, while comprising no startling departure, embodies a number of detail improvements, more especially as regards the clutch, carburettor and the brakes. The pressed steel frame is now narrowed in front to allow of a larger lock to the front wheels, and the wheel base has been lengthened. The four-cylinder engine has all its valves mechanically operated. The ignition, which is by low-tension magneto with pure nickel make and break tappets, is arranged to be automatically advanced or retarded in accordance with the speed of the engine. Both hand and foot accelerator levers are provided. The clutch is of an entirely new design, it being of the disc type. The change speed gear wheels are of smaller diameter than hitherto, the sprockets being correspondingly larger. The rear wheel brakes are of the internally-expanding variety; water-cooled band brakes are

Figs. 50 and 51.—Elevation and Plan of Fiat 24-32-h.p. Car.

provided on the differential shaft and also on the forward end of the side shaft in the gear box, the latter being automatically applied when the differential brake is full on. For the 1905 season three sizes are being made—16-20-h.p., 24-32-h.p., and 60-h.p.—all with four-cylinder engines.

MESSRS. GREGOIRE AND CO., of Poissy, exhibited an interesting light car which is about to be introduced into country by Messrs. Osborn and Lord. The vehicle is fitted with a pressed steel frame and a double-cylinder engine (80 mm. bore by 110 mm. stroke). The valves are all mechanically actuated off a single cam shaft. The radiator, which is carried in front of the bonnet, is of the framed ribbed pipe type, and the water is circulated on the thermo-syphon system. A two-way switch is attached to the dashboard, as are also sight-feed lubricators leading to the engine and change-speed gear mechanism. Three speeds and a reverse are provided with direct drive on top speed. The transmission is through a large diameter clutch, universal joint, gear box, and from the differential shaft by side chains to the rear wheels.

LES USINES DU PARTINIUM, of Puteaux, represented in this country by Messrs. Gautier and Co., had an excellent display of castings in their special light metal, Partinium, which, judging from the names thereon, appear to be used by all the leading motor-car builders in France.

Digitized by Google

The stand of the RICHARD-BRASIER CO. was continuously surrounded by a crowd of admirers, the attraction being the identical car on which Thery won the 1904 Gordon Bennett race, the cup itself being displayed on the bonnet of the vehicle. The 1905 models of the Richard-Brasier cars, the British agents for which are Messrs. Mann and Overton, comprise 8-h.p. double cylinder, and 12-16-h.p., 16-20-h.p., 24-30-h.p., and 40-50-h.p. four-cylinder cars. Except that the 8-h.p. car has only three speeds forward in addition to the reverse, while the others have four, the following remarks apply to all five vehicles. The main frame is of stamped steel, the engine and gear being supported on a secondary frame of tubular construction. The cylinders, which are cast in pairs, have mechanically-operated inlet valves, these being set on the opposite side to the exhaust valves. Magneto ignition is being retained, as is also the thermo-syphon system of water circulation in conjunction with a fan-cooled radiator. We noticed that the radiating surface has been increased and the fan improved; it may be added, however, that a pump is used on the 40-50-h.p. car. The carburettor is an automatic air-regulation one of the company's own patent; it comprises two spraying nozzles set at an angle to each other, similarly to twin burners in acetylene

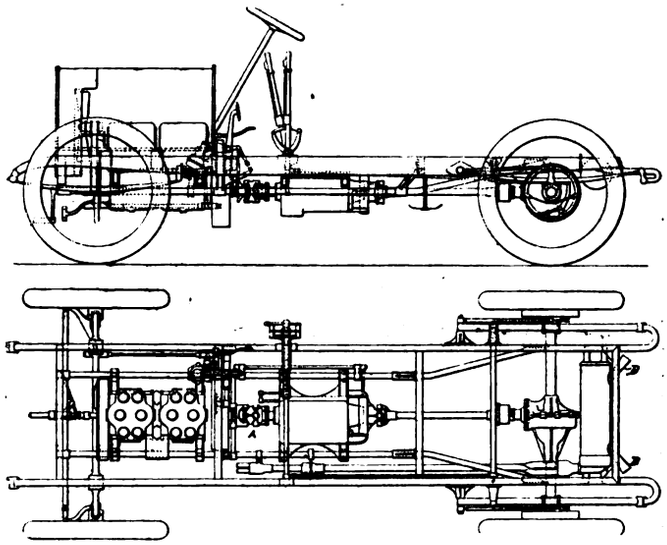

Fig. 52 and 53.—Elevation and Plan of 16-20-h.p. Richard-Brasier Car.

lamps. Except in the case of the 40-50-h.p. car, which is chain driven, the transmission is by means of a cardan shaft and bevel gear on to a live axle. A double universal joint A is introduced (Fig. 53) between the engine and gear-box, this not only relieving the shafts of the latter of all strain, but permitting the clutch to be dismounted without interfering with the gear box in any way. With the object of rendering the cars quieter than ever, and also of keeping down the dust, a new form of silencer is being adopted; it is of large size and is placed transversely across the rear of the car, the burnt gases finally emerging through two flattened pipes B projecting at an angle to the silencer. Enclosed internally-expanding metal-to-metal brakes are now fitted to the hubs of the rear wheels, while a point which will appeal to all who have suffered from "back kicks" of the motor, owing to the ignition not having been retarded, is an arrangement whereby the act of putting the starting handle into gear at the same time automatically retards the ignition; the moment the handle is released the ignition returns to its normal position. Long springs are employed, and we notice that the Truffault anti-shock device hitherto only found on Peugeot cars has been adopted. The frames are of sufficient length to allow roomy side-entrance bodies to be fitted.

A somewhat novel and strange-looking two-seated vehicle was exhibited by LA SOCIETE INDUSTRIELLE D'ALBERT, of Albert (Somme). It is known as the Rochet cab and is illustrated in Fig 54. As will be seen, it is entirely enclosed, the driver sitting and controlling the car entirely from the interior. The 4½-h.p. water-cooled engine is placed at the rear, driving direct on to the differential through the gear, which gives two speeds and reverse. A similar vehicle but fitted with a separate driver's seat was also shown, this being eminently suited for doctor's use.

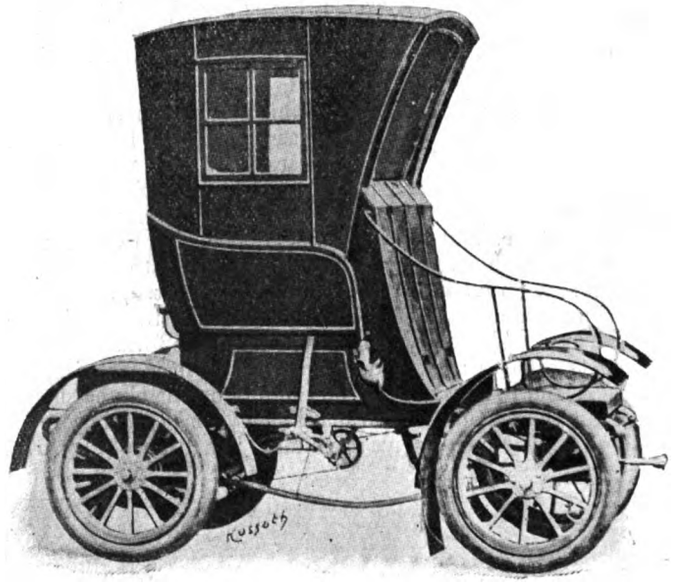

Fig. 54.—The Rochet Cab.

Messrs. CH. MILDE, FILS, AND CO. had an interesting stand on which were shown both electric and petrol-electric cars. The Mildé electric vehicles have already been described in the *Journal*. The motor is of the compound-wound differential type, carried at the centre of the hind axle and driving both rear wheels through internal spur gearing. Although larger batteries can be fitted, the standard one consists of forty-two cells, sufficient for a run of about forty miles on one charge. Fig. 55 illustrates

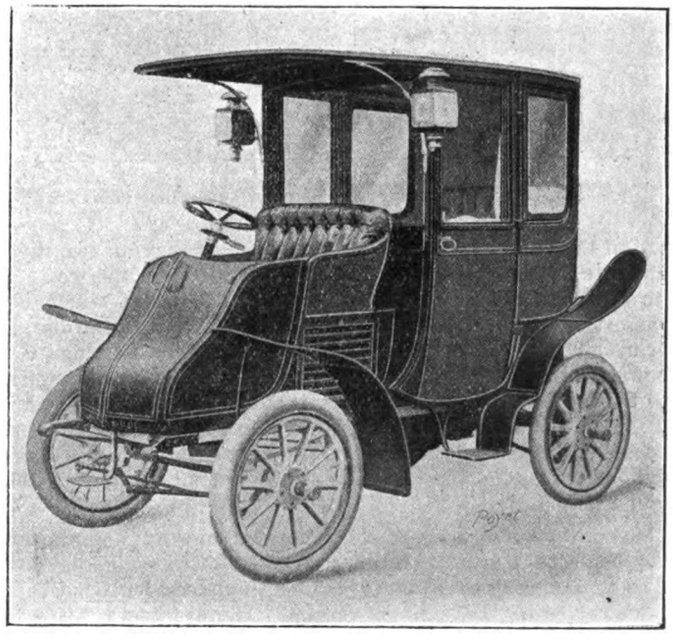

Fig. 55.—The Milde Electrical Coupe.

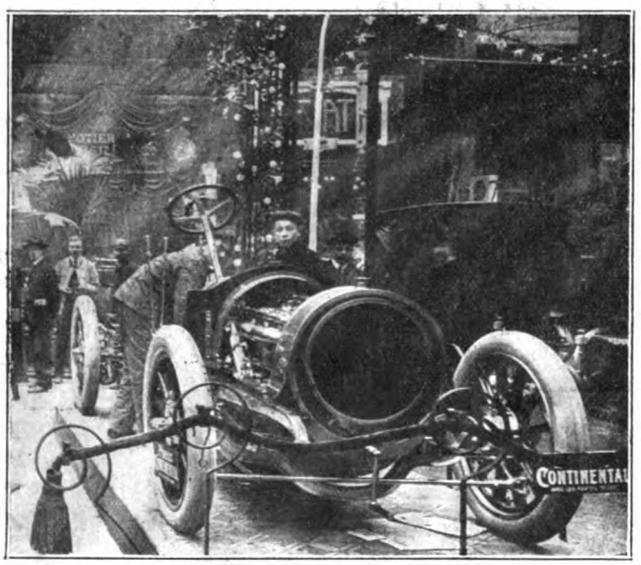
the latest type of Mildé electric car, specially designed for the use of travellers, doctors, and other professional men. As will be seen, it is of neat design, a noticeable feature being the provision for the protection of the driver. Since the Mildé petrol-electric car was first introduced it has been considerably

Digitized by Google

improved. It is being made in two sizes, 6-h.p. and 12-h.p., the first having a single-cylinder and the second a double-cylinder petrol motor. In this system the current generated by the dynamo is sent to a light battery of accumulators located under the rear seats, and thence to the electric motor. The car, having its own power-generating mechanism, is therefore not confined to town work, but can be used as a touring vehicle, while the engine and dynamo can even be used as a portable electric lighting plant.

The GILLET-FOREST Co., which has hitherto advocated the horizontal type of engine, has fallen into line with other makers, and exhibited a range of cars fitted with vertical motors. The latter are made under licence from La Société Metallurgique, an important Belgian concern, and are built in a number of sizes, including 8-h.p. and 12-h.p. two-cylinder and 16-h.p., 24-h.p., 30-h.p., and 40-h.p. four-cylinder. The main features are pressed steel frames, an internally-expanding metal clutch, and a spring drive on the rear end of the cardan shaft, the transmission being by live axle. The expanding clutch takes the form of two brake segments, which are expanded against the inside surface of the flywheel rim by means of a cone sliding on the clutch-shaft, and actuating the segments by means of short arms carrying rollers at their ends. The spring drive is mounted in a drum, *b* (Figs. 57, 58),



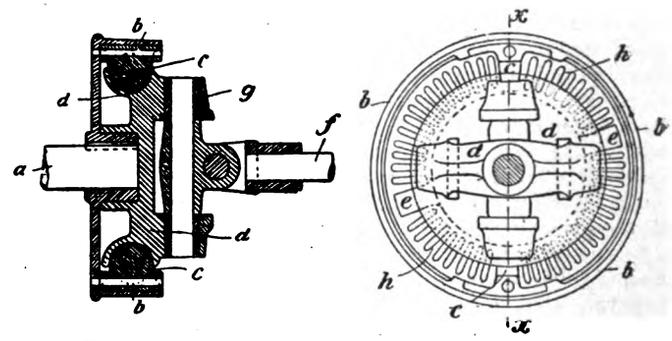


Fig. 56.—Front View of 40-45-h.p. Delaunay-Belleville Car.
(See page 893 last issue).

set on the end of the bevel pinion spindle, *a*, having two lugs, *c*, opposite to each other projecting inwards from the rim. The cardan shaft ends in a forked piece, *d*, each end of which bears against one end of a spiral spring, *h*, laid round the disc, and bearing as to its other end on one of the projecting lugs, *c*, the power being transmitted through the forked ends, the springs, to the lugs on the drum, and by the latter to the bevel pinion. The device is claimed to prevent shock on the bevel drive and to considerably reduce the noise. The horizontal type of engine is still employed in the Gillet-Forest industrial vehicles of 8-h.p. and 12-h.p.

An ingenious form of clutch is used on the "Radia" cars of the SOCIETE L'AUTOMOTRICE, which exhibited a 35-h.p. *chassis*. The engine comprises four separate cylinders, with mechanical inlet valves in the cylinder heads. The flywheel is made with arms which act as a fan to draw a current of air through the radiator. The coil clutch is somewhat on the lines of the Mercedes, but is actuated in a novel way, the coil on the clutch shaft being tightened by means of a pedal-actuated leather cone, which can be brought into engagement with the flywheel. It is only when the leather cone is rotated by the flywheel that the coil is tightened on the shaft, and the power of the engine transmitted to the gear box. A special form of internally-expanding band brake on drums connected with the hubs of the rear wheels forms another feature worthy of notice in the Radia cars.

At the stand of LES USINES PRUNEL, Mr. Foster, of the firm of Messrs. Delamotte and Foster, the British agents, pointed out to us the new features. We first inspected the *chassis* of a 24–30-h.p. car, which has a pressed steel frame. The engine

Figs. 57 and 58.—Details of Gillet-Forest Spring Drive.

has four separate cylinders with the mechanically-operated inlets set on the opposite side to the exhaust valves. In addition to the water circulating pump, the engine is provided with a pump which ensures a constant supply of oil to the various bearings. The gear-box, which gives four speeds and a reverse, is so arranged that it can be removed from the frame with a minimum of trouble. The car has wheel control, push pedals, metal-to-metal expanding brakes and other features of modern vehicles. The Prunel cars also include a double cylinder 10-h.p., a two-cylinder 12-h.p., a single-cylinder 9-h.p, and a four-cylinder 16–20-h.p., all of which appear to be of sound construction and of moderate price.

An extensive range of cars is being made by the DELAHAYE COMPANY for next season, extending from 8 to 25 h.p. They comprise a number of special features, and are excellent specimens of modern automobile construction. The 12-h.p. car is provided with a twin-cylinder vertical engine (100 mm. by 140 mm.), while those of the 16-h.p. and 25-h.p. vehicles have four separate cylinders with the mechanically-operated valves arranged on each side. The larger cars are driven by side chains, and in the 12-h.p. and 24-h.p. types the gear-box does not enclose the differential; in this way, by increasing the length of the shaft between the gear-box and the differential, any desired length of frame for side-entrance cars can be obtained. Among other new features in the Delahaye cars are a water-cooled exhaust, large push pedals of the Mercedes type and double-shaft change-speed gear.

A somewhat novel form of *chassis* construction is adopted by Messrs. LUC COURT AND CO., Lyons, who exhibited a 20–24-h.p.

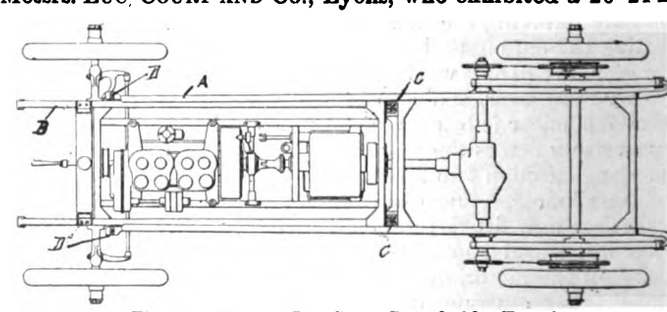

Fig. 59.—Plan of Luc-Court Detachable Chassis.

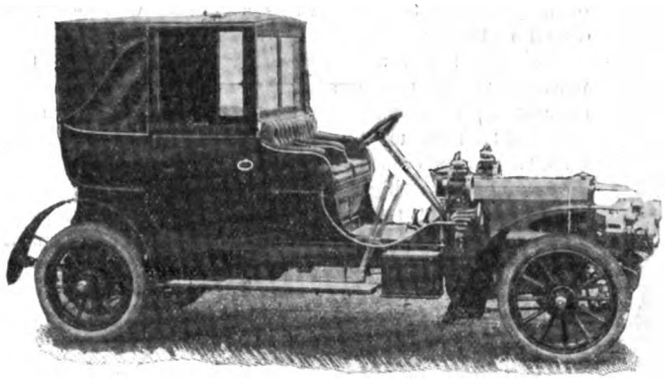

four-cylinder car, built on their special system. The frame is in two parts; one, A, carries the differential shaft and rear axle, and is of the usual length; the front wheels, engine and gear-box are mounted on a separate frame, B. The two parts of the frame are bolted together at the points C, D, so that they can be readily detached when necessary for repairs. In other respects the vehicles follow the usual lines of modern chain-driven vehicles.

(To be continued.)

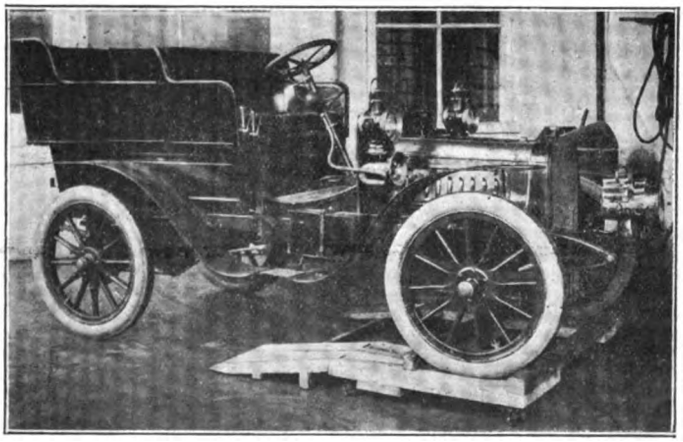
HERE AND THERE.

THE accompanying illustration depicts one of the latest 15-20-h.p. "Brooke" landaulets. The engine is of the four-cylinder type and is fitted with the Brooke new automatic carburettor, which renders it very silent and flexible. The long pressed steel frame enables a body with a wide side entrance door and a

The "Brooke" 15-20-h.p. Landaulet.

large amount of room at the back to be fitted. The wheel base is 10 ft., but, owing to the wide gauge, Messrs. J. W. Brooke and Company, Limited, state that a big lock is obtained, the car, even with this wheel base, being as easily manipulated as one with a base of 7 ft. 6 in.



THE first annual subscription dance of the Blackheath Automobile Club will be held in the Concert Hall, Blackheath, on the 28th prox.

THE DELAHAYE CO. have lately completed a 12-h.p. hospital van for the Associacao dos Empregados No Commercio, of Rio de Janeiro, Brazil.

THE GENERAL PETROLEUM CO. are now supplying their Shell motor spirit in gallon as well as two-gallon tins, a convenience for motor-cyclists.

THE AMERICAN MOTOR CAR AGENCY have recently shipped "Ford" cars to Durban and Cape Town, and also a 10-h.p. specially geared car to Captain Bell, of Malta, for military work.

WE illustrate herewith a small platform turntable Messrs. W. H. Johnson and Sons have used for some time with great success in their Motor Works at King's Lynn, and the great utility of which will be seen at a glance. The table, which is supported on four strong castors, can be folded up to economise space. When required for use the wedge boards are turned

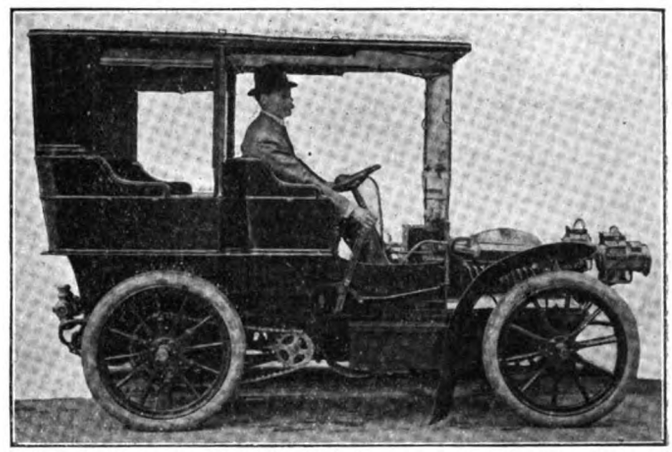
down and the car driven on to the platform; it is then easily pushed round, the whole operation occupying about thirty seconds. Messrs. Johnson point out that this method of turning cars round in a workshop not only saves time, but also a considerable strain on the steering gear.

THE HYDE RUBBER WORKS, LIMITED, are making additions to their manufacturing plant.

JUST over 300 licences for motor vehicles have been issued in Brighton during the year now closing.

THE Austrian Club has officially entered three Austrian Mercedes cars for the 1905 Gordon Bennett race.

CLIMAX MOTORS, LIMITED, has been registered with a capital of £5,000, to manufacture and deal in motors and vehicles.



AN automobile school is to be established in San Francisco, U.S.A., under the auspices of the Young Men's Christian Association.

A PROPOSAL is being made to widen the county bridge carrying the main London and Eastbourne road over the river Medway near Forest Row.

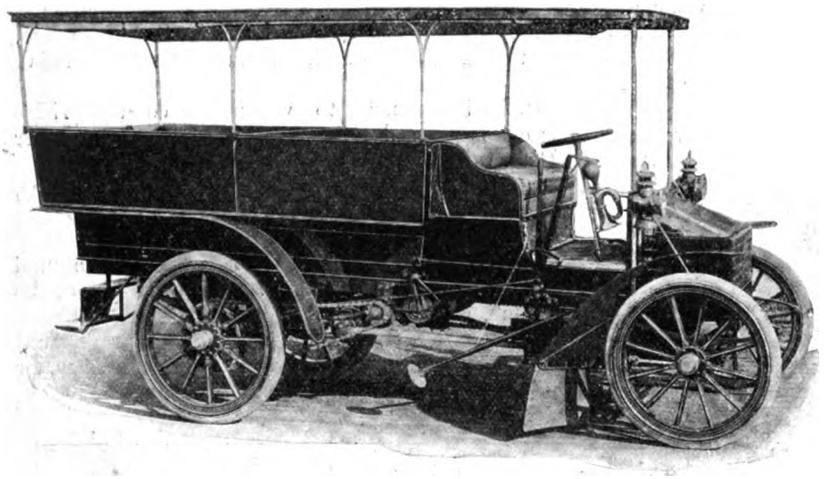
MR. LEONARD BAYNES, 15, Kensington Court Mansions, W., has been appointed wholesale agent for the Wellsaline lubricants in the London district.

THE Eastern Counties Automobile Club has held its annual dinner at the White Hart Hotel, Ipswich. Mr. F. L. Bland, the chairman of the club, was in the chair.

THE Direct Motor Company, Limited, has been registered with a capital of £5,000, to manufacture, hire, purchase, or otherwise acquire, and deal in and with motor-cars.

Mr. W. R. Poynton, a well-known contractor and builder, of Durban, South Africa, on his 15-h.p. Napier Car.

HIS ROYAL HIGHNESS THE PRINCE OF WALES has consented to be Vice-Patron of the Automobile Club of Great Britain and Ireland, His Majesty the King being Patron.



FROM the Panhard and Levassor Company, Paris, comes a handsomely got-up booklet descriptive of their immense works and of the latest models of Panhard vehicles, of which very clear illustrations are also given. Incidentally, it may be mentioned that to meet the demand for their cars the company are equipping a large branch factory at Rheims.

MESSRS. H. E. HALL AND CO., of Tonbridge, have secured the sole agency for the United Kingdom for the Bergmann "Liliput" two-seated car. The transmission is by friction drive, in which the necessary pressure between the friction disc and the fly-wheel is produced automatically by the forward movement of the driving wheels. The little vehicle, which sells at a popular price, is stated to be an excellent hill-climber.

A NEW idea in motor-hoods for lady automobilists has been brought out by Messrs. Lovegroves, of Piccadilly, W. The hood and shoulder tippet are one, and the former can be drawn up as tightly as necessary by the ribbon strings. In this way the wearer becomes entirely shielded from contact with the wind. It fits closely all round, and will in no way disturb the most elaborate coiffure. One good type of hood is made of soft pale blue leather, and lined with pure white fox. The design can, however, be executed in any colour and fur to suit any taste and requirements.

Digitized by Google

THE accompanying illustration shows a special 24-h.p. passenger and mail van recently completed by the Wolseley Company for service in South Africa. The car is arranged to carry six passengers, exclusive of driver and conductor, and about half a ton of mails and luggage, the latter being carried in the space immediately behind the driver's seat. The total weight of the vehicle empty, but in running order, is about 30 cwt. A

standard 24-h.p. four-cylinder engine is fitted and four speeds ranging from seven to twenty-six miles per hour. The radiator is of the "Wolseley" type, and is made exceptionally large to enable the vehicle to run in a hot climate. The draught is induced by a fan driven by the motor.

THE COVENTRY WORKS, LIMITED, has been registered with a capital of £10,000 to carry on the business of manufacturers and factors of and dealers in motor-cycles and vehicles. The registered office is at Coventry Works, Arthur Street, Small Heath, Birmingham.

AUTOMOBILES and parts to the value of £26,178 were exported from the United States during October last, as compared with only £23,826 in the same month a year ago. For the ten months ending with October, the exports totalled £315,375, as against £262,392 for the corresponding period of 1903.

AT the Paris *Salon* about 700 wheels were fitted with Continental tyres—a great increase on the number exhibited last year. At the Continental Company's stand the chief interest centred round the model of Monsieur Lebaudy's airship. The silk skin used for the original airship was manufactured by the Continental Company, and this model was made by the man who constructed the airship for M. Lebaudy.

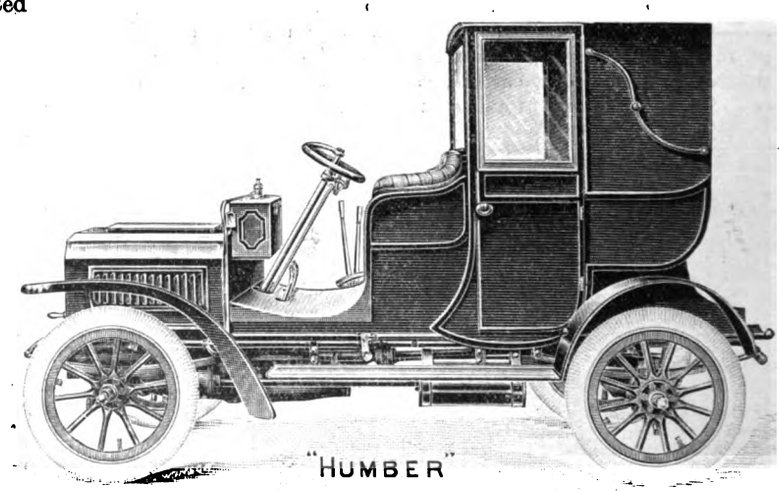
MESSRS. RENAULT FRERES, LIMITED, has been registered with a capital of £50,000 to acquire an English patent relating to motor-cars, now held by Messrs. Renault Frères, of Paris; to make and sell motor-cars and accessories under such patent in the United Kingdom; to acquire the agency for the sale of such cars recently held by the Roadway Autocar Company, Limited, and the lease of the premises on which the last-named company has carried on its business. The first directors are Messrs. F. Renault, W. L. McBride, G. de Wilde, H. Kapferer, and the Hon. E. A. Stonor.

A demonstration with the Pedrail Tractor has been made before the Liverpool Chamber of Commerce. A trial of this engine was recently made from Lincoln to London, 135 miles by road, under observation by respresentatives from the War Office and the Local Government Board, extending over a week. The Pedrail Tractor, a loaded wagon and a War Office van for the official observers took part in the trial, the total weight of the train, including the Pedrail Tractor, being about 13 tons. There was an absence of damage to the road surface as well as no signs of any appreciable wear on the rubber soles of the Pedrail feet.

THE Highways Protection League has been formed "to combat the motor nuisance."

STEAM motor-carriages are being introduced on their local services between Seacombe and Wrexham by the Great Central Railway Company.

THE Great Western Railway Company are extending the rail motor-car system to the Kidderminster, Bewdley, and Stourbridge districts. Cars have been built for service on branch lines in these localities, and they will be introduced in the New Year.



FRANCE has added another new word to the vocabulary of motoring — "domobile" — signifying covered touring cars with sleeping accommodation.

THE Purdue University, of Lafayette, Ind, U.S.A., is now completing plans for the installation of an automobile testing plant. It is intended to conduct this department somewhat along the lines of its locomotive testing plant, which has been in successful operation for more than ten years.

A COMPETITION for the best decorated stand was held in connection with the recent *Salon* in Paris. The Grand Prix du Conseil Municiple (gold medal) was awarded to the Delaunay-Belleville Company, the Grand Prix de L'Automobile Club de France (gold medal) to the Hotchkiss Company, gold medals to Richard-Brazier and Ducellier; silver-gilt medals were awarded to the following exhibitors, De Dietrich, Fémina, Fiat, La Francaise, Markt, Panhard, Renault, and La Société d'Industrie Mecanique.

AT the last meeting of the Ryde Rural District Council, the General Purposes Committee recommended that a letter be written to the Secretary to the Motor Omnibus Company, stating that, in the opinion of the Council, many of the roads on the routes which they have scheduled are unsuited to the proposed traffic, and that the Council will not hold themselves responsible for any accident which may occur owing to the narrowness of the roads, or to overhanging trees or shrubs, or to the weakness of the extreme sides of the roads.

THE new catalogue issued by Messrs. Alfred Dunhill, Limited, as a Christmas greeting is a combination of historic pictures with the fashions of the time. Interspersed with the pages illustrating their special "motorities" are the photographic views taken by Mr. Edward Kennard during the eliminating race in the Isle of Man; previous reference to these illustrations has

The Humber 10-12-h.p. Landaulet.

been made in our columns. Other pictures in the catalogue depict the Mocravat—a cleverly-designed muffler completely covering the throat while motoring. It fits closely to the neck and is adjusted by means of two stud fastenings at the back. Gauntlets, fur gloves and mittens for winter use are also illustrated, together with goggles, match-box cases, and other minor accessories, of which Messrs. A. Dunhill have an almost bewildering selection.

CORRESPONDENCE.

THE USE OF THE ACCELERATOR.—FOOT v. HAND CONTROL.

To the Editor of *The Motor-Car Journal*.

Sir,—In regard to the correspondence which is taking place in the columns of the *Journal* in reference to the use of the accelerator—foot v. hand control—I agree entirely with the remarks made by Mr. Hutton, that is to say, that the happiest form of control is a combination of foot and hand control. For instance, the system adopted on the Crossley car is as follows:—There are two levers on the steering wheel, one to control the timing of the ignition and the other the throttle. The throttle lever can be set in any position according to the engine speed desired. For ordinary driving in traffic and in places where there is a great variation of speed required, the throttle lever is brought back to the position which reduces the engine speed to a minimum, and then the use of the foot accelerator enables the car to jump forward in an instant without taking either hand off the steering wheel. When the foot is taken off the foot accelerator, the throttle immediately goes back to the slow position to which it is set by the lever on the wheel.

This is practically the same control as that adopted by Jenatzy in the Gordon Bennett race in Germany. It is wonderfully effective, very quick, and has the advantage of both systems combined. The disadvantage in connection with the Mercedes control is that to retard the engine speed it is necessary to take one hand off the steering wheel. In an awkward place this might be dangerous. Foot and hand control is the right combination.—Yours truly,

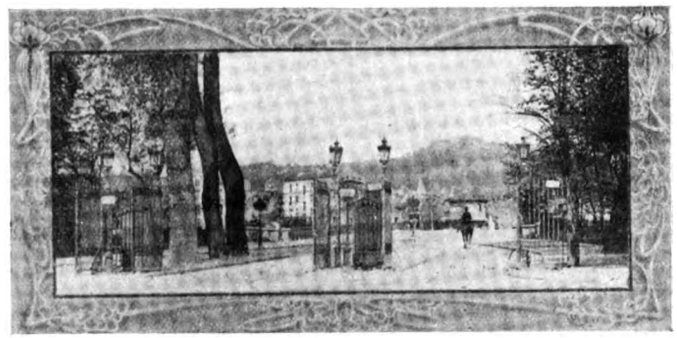
Chas. Jarrott

To the Editor of *The Motor-Car Journal*.

Sir,—I am glad you invite discussion on this topic. I agree with much that Mr. Percy Richardson has said in his article. My experience of the foot pedal accelerator on a 12-14-h.p. Clement, which I drove from Windermere to Southport in safety, though with much nervousness, ended up in my driving the front of the car through a light board partition, just as I finished my journey, on entering my motor-house. Instead of putting my foot on the brake pedal I put it on the accelerator, with the result as above stated. For the moment I had lost my head, or the power to think, just at the critical moment; but this is just the thing to be guarded against, and why the control of a car should be made as proof as possible against this weakness of losing one's head.

I am not a novice, having driven cars for the past six years. I will not tolerate a foot accelerator on any car of mine. My ideal control is as follows:—(1) The car must be fitted with a good carburettor with automatic air supply, so as to dispense with the need of any levers or handles for this purpose being placed on the steering-wheel. (2) There must be two throttles, one to be operated by hand from the steering column, and the other must be connected by positive and well-adjusted levers and connections to the clutch pedal. This now leads me to another point. With this arrangement the governing mechanism, with all its complications and expense, can be abolished, and all the difficulties suggested by Mr. S. F. Edge in his letter in your issue of the 24th inst. will cease to exist. Of course there would be a lever or handle to advance or retard the ignition. We know that several makers are working on these lines, but why all do not do so I cannot understand, as the method is so simple. The law of evolution, I presume, is the reason, and it takes time to find out improvements and develop them.

Further, I am against the use of wire cables as connections for the control levers. I do not care for the idea of the control levers being placed on the top of the steering-wheel, owing to the complications which arise in the mechanical fitments made necessary on the steering column. The simpler forms of plain levers, rods and bell cranks appeal to me as being more practical and workable than many of the ingenious and complicated forms which one often meets on the best cars. I speak from experience on the road and not from theory.—Yours truly,



J. Coop.

To the Editor of *The Motor-Car Journal*.

Sir,—I read Mr. Percy Richardson's article in your issue of December 10th with much interest, and can quite endorse his remarks as to the feeling of security engendered by the knowledge that under one's foot is a control pedal to which the car will instantly respond in case of need. I have driven now for eighteen months a 14-h.p. Chenard and Walcker, and their system of control seems to me, except in one point, quite perfect. The usual change-speed lever and hand-brake are the only two parts the right hand is concerned with. The left hand never need leave the steering wheel, for there is nothing attached to it or its pillar. So much for the hand control. The left foot has, like the left hand, the post of honour, and has to manipulate the governing pedal, which, on this car, regulates the duration of the lift (not the extent, which is always constant) of the inlet valves, and hence the power and through it the speed of the car. The right foot has an easy time of it, except when changing speed or applying the foot brake, for its function is the manipulation of the clutch pedal. The clutch has a double duty. Its leather covered cone face, as usual, connects the flywheel and gear-box; but it has a reverse face of metal, and when the right foot depresses the pedal to the extreme, this reverse face is brought in contact with a stationary rim, and, by braking the clutch, gives a very sweet running and at the same time powerful brake, through the gear-box, to the car. The right foot soon acquires the knack of depressing to the right extent to free the clutch when changing speed, without fear of, by overdoing it, applying the brake; but, to aid the novice, the makers fit a third pedal, the function of which is to declutch only, but which in practice can be discarded, playing the part of leading rein until the rider can manage his mounts. The one drawback that this concentration of control has is that there is a chance which ought to be remote, but which is there all the same, that, if the gear is missed when changing up or down, the clutch brake is disconnected and one has to rely on the powerful hand brakes. With so flexible an engine, this, in practice, is of little moment, for in times of emergency the usual want is not to change speed, but to apply the brake, and this can be done at once by depressing the right pedal, thereby in one action releasing the clutch and putting on the brake. The hands, meanwhile, are absolutely free, and this very fact adds much moral support if the driver finds himself in a tight place, the word being "Forward: both feet up. Stop her: both feet down. Hands: stand by." The timing of the spark in the car being constant, when once set, there is no sparking lever to think of, and so flexible is the left foot control that the car will run down to five miles an hour on fourth speed.

If the trade would only adopt as a standard maxim "one foot one job," and a spare hand free to help in case of need, as Mr. Richardson suggests, one would hear less of cars going wrong owing to their new owners putting accelerators and brakes in simultaneous action, acting unconsciously on "Punch's" advice, as pourtrayed in his cartoon of October 26th. Owner (by roadside, to wife sitting in car, which starts backing downhill): "Pull everything you can see, and put your foot on everything else!"—Yours truly,

Cecil B. Cave-Browne-Cave.

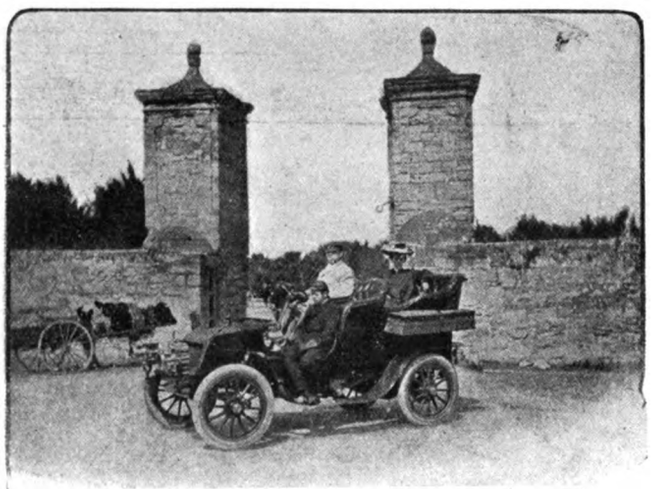
The Port de Suresnes—A well-known spot in the Bois de Boulogne, Paris.

THE COST OF UPKEEP.

To the Editor of *The Motor-Car Journal*.

Sir,—I have read with much interest many letters on this subject, and I feel my own experience may be interesting and perhaps useful to your readers. I have been using a car in my business since 1897. Previous to 1897 for twenty-five years I had kept a horse, and sometimes two, to do the same work I have since been doing with my car. I am, therefore, after seven years' experience, well able to form an unmistakable opinion as to the relative expense and convenience of motor and horse.

I generally paid fifty or sixty guineas for a horse; my dogcart and harness, I suppose, were worth another thirty guineas; my coachman had 26s. per week. In 1897 I bought one of the first 3½-h.p. Benz cars, second-hand, two speeds, no reverse, solid tyres. For this I gave £92 10s.; new sprockets, chains, and a few etceteras brought the total cost up to £114. I drove this little car nearly 14,000 miles in about eighteen months, when I sold it, buying another at once. Since then I have had an ever present desire to drive "another car." My purchases have included a Bollée—two or three French cars, and two or three English. I am naturally fond of anything mechanical; this gives me such interest in any car that I am never quite happy unless I thoroughly understand it. I have bought a lathe, a vice, and a few tools, which enable me to do almost any repair short of forging. Since the repair of my first Benz, I have not spent £1 for mechanical assistance. I have had two slight accidents—once I cannoned a cow, and on another occasion a dog got mixed up with my steering arrangements, which caused a cannon with a chapel, the expense being—the cow episode, nothing—the dog 28s., which the owner of the dog paid.



Now with regard to expense—keep of horse, shoeing, and vet., 15s. per week; man's wages; 26s., stable accommodation when on long journeys average 3s. per week; total £2 4s.; average mileage seventy miles per week. Expense of car—petrol 6s., boy to wash and clean 8s., lubricating oil, charging accumulators, say 4s.; total 18s. per week; average mileage 120, time spent on road not more than driving a horse seventy miles. This shows an actual save of 26s. per week, plus an additional

Digitized by Google

fifty miles. You will notice I have not allowed anything for depreciation of cars. I consider depreciation on horse, trap, and harness is quite equal to that on cars. Another advantage in favour of cars is, when driving my horse in business I was obliged to have my man with me, because the nature of my business is such that during a day's drive I make five or six stoppages, each of about an hour, but I go alone in my car, leaving the boy at home to clean windows, run errands, and to make himself generally useful. I do not think anything can prove more conclusively than this the advantages of a car, but such a result can only be obtained by one who takes the trouble to understand his car, has sufficient mechanical ability to do his running repairs himself, and drives carefully. Judging by my experience with my first car, motoring is an expensive luxury if one calls in a repairer for every little adjustment which may be necessary.

Then again many would-be motorists fear the initial expense. This need not be heavy, because £50 or £60 is quite sufficient to purchase a car which will show the same result as my own, viz., a reduction of 26s. weekly as compared with a horse, provided one has a little mechanical ability and some perseverance. Any average man can easily gain as much knowledge of his car in a couple of months as the average chauffeur. A car costing, say, £60 will, of course, not be a Mercédès, but it will be one which will travel fifteen or twenty miles an hour, and last for some years. On the other hand, if one is more ambitious, and the purpose for which he intends using his car justifies the outlay of £100 or more, I should not purchase such a car as referred to, although one would be as reliable and probably as fast as the other. There is not the slightest doubt in my mind that anyone who keeps a horse, and the necessary man, for the purpose of his business can cover 50 per cent. more ground in the same time, save at least 25s. per week, and get an amount of pleasure unknown to any but motorists, and will after a few months come to the same conclusion as myself, *i.e.*, horses are slow, expensive, and dangerous.—Yours truly,

E. W. 125.

The Old Style and the New.

THE CONSTRUCTION OF SILENCERS.

To the Editor of *The Motor-Car Journal*.

Sir,—Referring to the article on this subject in the *Journal* of the 26th ult., it does not seem to be fully appreciated that to secure a noiseless discharge of the products of combustion in a petrol motor, it is necessary only to deprive these products of their heat. Heat is the cause of the pressure of the gases, and the sudden variations in pressure cause the puffing noise, which it is the object of the silencer to reduce to a minimum. The noise may be reduced essentially in two ways—by placing obstructions in the passage of the exhaust gases, thus causing their gradual expansion, and by depriving the exhaust gases of their heat. In most silencers the gases are forced through tortuous passages and small perforations, which greatly obstruct their free discharge, and while this secures the desired result of dampening the noise in a fair degree, it also causes considerable back pressure on the engine, thereby reducing the power of the latter. On the other hand, cooling the exhaust gases reduces their tension and the noise of discharge without increasing the back pressure. Of course, the expansion itself results in reducing the temperature of the gases, as the energy necessary for the expansion is abstracted from the heat of the gases; but the cooling effect referred to here is due to radiation. On this account I consider that the silencer should therefore be placed where it is subjected to a cooling draught, and should not be covered with asbestos, as it frequently is. The exhaust gases contain a considerable proportion of water vapour, and if the cooling facilities of the silencer are sufficient to partially condense this vapour, the noise of the exhaust will be much reduced.—Yours truly,

W. T. Millburn.

MOTOR-DRIVERS' ORGANISATION.

To the Editor of *The Motor-Car Journal*.

Sir,—In reference to "Terminal's" letter, I quite agree with him that it is time a motor-drivers' union was established. The society could be conducted on the same lines as others are, and every driver ought to have served as much apprenticeship as a motor mechanic—say about three years—and be able to prove himself capable of taking charge of any car. There are too many so-called "motor-drivers" who have had about three weeks' experience and paid a fee of about £5 for it. I myself have paid no fee and have no certificate, but I have my indentures to prove that I have served six years as bound apprentice to the motor trade. But what use are they? I cannot get employment. I have been looking for a situation now for eight weeks, and it is not for the want of trying that I am still out of work; it is owing to these so-called "drivers" offering to work for a small wage. I ask for a living wage. I think no qualified driver ought to work for less than 30s.

Another thing I wish to bring under your notice is the way drivers' licences are issued. Anybody can get a licence even if he has never seen a car before. Now I think if every one who applied for a licence had to pass a strict examination in the mechanism of cars there would be fewer accidents, and the owner and manufacturer would benefit thereby.—Yours truly,

A Would-be Member.

AN INTERESTING MOTOR QUERY.

To the Editor of *The Motor-Car Journal*.

Sir,—In connection with "Inquisitive One's" inquiry, I have been the owner of a motor launch for some years past, and have often noticed a similar state of things at sea after nightfall. The engine appears to go better and the boat faster, but in my opinion it is an illusion. Every boat and every car appears to travel faster by night, owing to the quicker disappearance of the wake in the former case, and of the road marks in the latter. It is well known that professional fishermen attribute the apparent increase in their boat's speed after dark to the "oil on the water at night," which is obviously imagination. A motor will naturally appear to a listener to throw better and produce better-defined explosions at night owing to the increased silence of the surroundings, and the greater attention one naturally concentrates on it in the dark. I have more than once taken the engine speed at night when I felt convinced that both motor and boat were doing more than usual, and both the revolutions per minute and the time of journey proved to be quite normal.—Yours truly,

Marine.

THE GRAPHITIC LUBRICATION OF PETROL MOTORS.

To the Editor of *The Motor-Car Journal*.

Sir,—Referring to the article on this subject in the last issue of the *Journal*, I have used graphite in petrol engines for a number of years, but mixed with the oil in the crank chamber. It is not only good for the cylinders, but for the crank bearings also. The only difficulty was to obtain graphite free from grit; this was overcome by washing and filtering.—Yours truly,

W. D. Bowman.

MOTONEER.

To the Editor of *The Motor-Car Journal*.

Sir,—I suggest as a suitable designation for a motor engineer the word "Motoneer," thereby meaning anyone connected with motor engines and applying in the same way as "Engineer" would be for one associated with, say, steam engine work. The word *chauffeur* means, I take it, the driver, but this hardly comprehends what is altogether intended to be expressed. You might perhaps put this before your readers, as the French word now in use is not altogether palatable nor pronounceable by the Britisher.—Yours truly,

Motoneer.

CHARGING ACCUMULATORS.

To the Editor of *The Motor-Car Journal*.

Sir,—I have read with much interest in your valuable *Journal* many useful queries, electrical and otherwise, and should be glad if you or someone who has had some experience with the Boron cells could give me a few hints. Having some trouble in getting my accumulators charged, I purchased a set of six Boron cells so that I might charge them myself. I have not, however, up to the present found them so satisfactory as I anticipated. The chemicals I use in each jar (or cell) are as follows:—4 oz. bichromate soda, 4 oz. of vitriol diluted with water to the capacity of the jar; porous pot (or cell), diluted vitriol 1 part to 12 of water. The zincs I find use up very quickly, even if they are kept well amalgamated. My accumulators are fifty and sixty ampère hours, and with six cells on I allow them twelve hours charging, and when taken off they register 4·5 volts. But with this charge the accumulators only run a four-cylinder car about 150 miles, sometimes less. The acid is about the right strength in accumulators, viz., 27 deg. Beaume. The chemicals I find have to be renewed practically every time, especially if left to stand a

Digitized by Google

few days, with the addition of new zincs very often, which makes the charging very expensive.

I think my failure is possibly due to not having the proper amount of chemicals. Therefore I shall be very grateful if someone who is using these cells and getting good results from them would be good enough to give me some information how to use them; also the cheapest and best house to buy chemicals and zincs. I think this would be a most interesting topic to others as well as myself.—Yours truly,

CELLS.

THE COST OF MOTOR-CARS.

To the Editor of *The Motor-Car Journal*.

SIR,—The demand of the general public is always for lower prices, but the public does not fully appreciate the fact that a lower price must necessarily mean a lower quality of material and workmanship, which will result in untold annoyances and troubles to the user, and, consequently, a higher cost in the end. The work a motor-car is called upon to perform is so severe that satisfaction can only be expected if both material and workmanship are of the best—and these are always expensive. There are, I find, many members of the general public who are hugging the belief that motor-cars at present prices bring their manufacturers a net gain of several hundred per cent. Such a belief, however, is entirely unfounded; the profit is in most cases only a very reasonable one, and manufacturers who are determined to maintain a high standard of quality have been inclined to advance their prices rather than reduce them.

It is of the greatest importance to the industry in general that a high standard of quality be maintained. Cheapness of construction will lead to dissatisfaction, and the lasting injury that may be done by dissatisfied motorists is, to my idea, certainly a more serious consideration than the loss of a few customers who cannot discriminate between the good and the cheap, or who abstain from buying because, according to their ideas, prices are too high.—Yours truly,

ARIOSO.

REPAIR SHOP EQUIPMENT.

To the Editor of *The Motor-Car Journal*.

SIR,—In answer to "I. N. 26's" letter in the last issue of the *Journal*, it is a very difficult matter to give advice upon, as one always finds that for almost every repair that comes in a new tool is necessary, even if only a box spanner, but usually a fairly equipped shop suitable for engineering purposes would be found suitable also for car repair work. For first-class repair work machinery is indispensable, as in almost all cases lathe work is necessary. With regard to the cradle mentioned, this would answer very well, but personally I would recommend a pit, as much time is saved by the same.—Yours truly,

MOTOR MECHANIC.

QUERIES RE LIGHT CARS.—A VARIETY OF QUESTIONS.

To the Editor of *The Motor-Car Journal*.

SIR,—I should be glad if any readers of the *Journal* would give me some information on the following points. (1) Is it a serious objection to French and American cars that the screw threads are of different gauge to ours, so that if a nut is lost in a country place it may be necessary to write to town for another? (2) Does the carburettor of an Oldsmobile car ever get hot enough to melt solder? (3) Is there any advantage in putting puncture-proof jelly into a single-tube tyre?—Yours truly,

INQUISITIVE.

ON SIR HIRAM MAXIM'S BEHALF.

To the Editor of *The Motor-Car Journal*.

SIR,—We have been asked by our client Sir Hiram Stevens Maxim to call your attention to the advertisement which appears in your *Journal* of the Maxim Daniel Motor Company, 8, Boston Place, Marylebone, N.W., and to inform you that the name has nothing to do, either directly, or indirectly with him or any company with which he is connected or interested.

We think it only right to call the attention of yourself and your numerous readers and would-be motor-car purchasers to these facts.—Yours truly,

CROSSE AND SONS.

AMERICAN STEAM CARS.—Referring to the complaint in last week's *Journal* as to the difficulty of obtaining spare parts for steam cars, we are assured that this does not refer to the White Steam car.
